EXAMPLE 20-11 Suspending a current with a current. A horizontal wire carries a current $I_1 = 80$ A dc. A second parallel wire 20 cm below it (Fig. 20–25) must carry how much current I_2 so that it doesn't fall due to gravity? The lower wire has a mass of 0.12 g per meter of length.

APPROACH If wire 2 is not to fall under gravity, which acts downward, the magnetic force on it must be upward. This means that the current in the two wires must be in the same direction. We can find the current I_2 by equating the magnitudes of the magnetic force and the gravitational force on the wire.

SOLUTION The force of gravity on wire 2 is downward. For each 1.0 m of wire length, the gravitational force has magnitude

$$
F = mg = (0.12 \times 10^{-3} \text{ kg/m})(1.0 \text{ m})(9.8 \text{ m/s}^2) = 1.18 \times 10^{-3} \text{ N}.
$$

The magnetic force on wire 2 must be upward, and Eq. $20-7$ gives

$$
F=\frac{\mu_0}{2\pi}\frac{I_1I_2}{d}l
$$

where $d = 0.20$ m and $I_1 = 80$ A. We solve this for I_2 and set the two force magnitudes equal (letting $l = 1.0$ m):

$$
I_2 = \frac{2\pi d}{\mu_0 I_1} \left(\frac{F}{l}\right) = \frac{2\pi (0.20 \text{ m})}{(4\pi \times 10^{-7} \text{ T} \cdot \text{m/A})(80 \text{ A})} (1.18 \times 10^{-3} \text{ N/m}) = 15 \text{ A}.
$$

* Definition of the Ampere and the Coulomb

You may have wondered how the constant μ_0 in Eq. 20–6 could be exactly $4\pi \times 10^{-7} \text{T} \cdot \text{m/A}$. Here is how it happened. With an older definition of the ampere, μ_0 was measured experimentally to be very close to this value. Today, however, μ_0 is *defined* to be exactly $4\pi \times 10^{-7} \text{ T} \cdot \text{m/A}$. This, of course, could not be done if the ampere were defined independently. The ampere, the unit of current, is now defined in terms of the magnetic field B it produces using the defined value of μ_0 .

In particular, we use the force between two parallel current-carrying wires, Eq. 20–7, to define the ampere precisely. If $I_1 = I_2 = 1$ A exactly, and the two wires are exactly 1 m apart, then

$$
\frac{F}{l} = \frac{\mu_0}{2\pi} \frac{I_1 I_2}{d} = \frac{(4\pi \times 10^{-7} \,\mathrm{T \cdot m/A})}{(2\pi)} \frac{(1 \,\mathrm{A})(1 \,\mathrm{A})}{(1 \,\mathrm{m})} = 2 \times 10^{-7} \,\mathrm{N/m}.
$$

Definitions of ampere and coloumb Thus, one ampere is defined as that current flowing in each of two long parallel wires, *I* m apart, which results in a force of exactly 2×10^{-7} N/m of length of each wire.

This is the precise definition of the ampere. The coulomb is then defined as being *exactly* one ampere-second: $1 C = 1 A \cdot s$.

566 CHAPTER 20 Magnetism

20-7 Solenoids and Electromagnets

A long coil of wire consisting of many loops (or turns) of wire is called a **solenoid**. The magnetic field within a solenoid can be fairly large because it is the sum of the fields due to the current in each loop (Fig. $20-26$). A solenoid acts like a magnet; one end can be considered the north pole and the other the south pole, depending on the direction of the current in the loops (use the right-hand rule). Since the magnetic field lines leave the north pole of a magnet, the north pole of the solenoid in Fig. 20–26 is on the right. As we will see in the next Section, the magnetic field inside a tightly wrapped solenoid with N turns of wire in a length l , each carrying current I , is

$$
B = \mu_0 I N / l.
$$

 $(20-8)$

If a piece of iron is placed inside a solenoid, the magnetic field is increased greatly because the iron becomes a magnet. The resulting magnetic field is the sum of that due to the current and that due to the iron, and can be hundreds or thousands of times that due to the current alone (see Section $20-12$). Such an iron-core solenoid is an electromagnet.

Electromagnets have many practical applications, from use in motors and generators to producing large magnetic fields for research. Sometimes an iron core is not present—the magnetic field comes only from the current in the wire coils. For some applications, the current-carrying wires are made of superconducting material kept below the transition temperature (Section 18–9). Very high fields can be produced with superconducting wire without using an iron core. No electric power is needed to maintain large current in the superconducting coils, which means large savings of energy; nor must huge amounts of heat be dissipated.

Another useful device consists of a solenoid into which a rod of iron is partially inserted. This combination is also referred to as a solenoid. One simple use is as a doorbell (Fig. $20-27$). When the circuit is closed by pushing the button, the coil effectively becomes a magnet and exerts a force on the iron rod. The rod is pulled into the coil and strikes the bell. A large solenoid is used in the starters of cars; when you engage the starter, you are closing a circuit that not only turns the starter motor, but activates a solenoid that first moves the starter into direct contact with the gears on the engine's flywheel. Solenoids are used as switches in many devices. They have the advantage of moving mechanical parts quickly and accurately.

Modern circuit breakers that protect houses and buildings from overload and fire contain not only a "thermal" part (bimetallic strip as described in Section 18–6, Fig. 18–19) but also a magnetic sensor. If the current is above a certain level, the magnetic field it produces pulls an iron plate that breaks the same contact points as in Fig. 18–19b and c. In more sophisticated circuit breakers, including ground fault circuit interrupters (GFCIs—discussed in Section 21-8), a solenoid is used. The iron rod of Fig. 20–27, instead of striking a bell, strikes one side of a pair of points, opening them and opening the circuit. Magnetic circuit breakers react quickly $(< 10$ msec), and for buildings are designed to react to the high currents of shorts (but not shut off for the start-up surges of motors).

FIGURE 20-26 Magnetic field of a solenoid. The north pole of this solenoid, thought of as a magnet, is on the right, and the south pole is on the left.

PHYSICS APPLIED **Electromagnets and solenoids**

(大) PHYSICS APPLIED Magnetic circuit breakers

The total current enclosed by the path shown is $I_{\text{encl}} = I_1 + I_2$.

FIGURE 20-28 Arbitrary path enclosing electric currents, for Ampère's law. The path is broken

20-8 Ampère's Law

In Section $20-5$ we saw that Eq. 20-6 gives the relation between the current in a long straight wire and the magnetic field it produces. This equation is valid *only* for a long straight wire. Is there a general relation between a current in a wire of any shape and the magnetic field around it? Yes: the French scientist André Marie Ampère (1775–1836) proposed such a relation shortly after Oersted's discovery. Consider any (arbitrary) closed path around a current, as shown in Fig. 20–28, and imagine this path as being made up of short segments each of length Δl . We take the product of the length of each segment times the component of magnetic field \vec{B} parallel to that segment. If we now sum all these terms, the result (said Ampère) will be equal to μ_0 times the net current I_{encl} that passes through the surface enclosed by the path. This is known as Ampère's law and can be written

AMPÈRE'S LAW

$$
\sum B_{\parallel} \Delta l = \mu_0 I_{\text{encl}}.\tag{20-9}
$$

The symbol Σ means "the sum of" and B_{\parallel} means the component of **B** parallel to that particular Δl . The lengths Δl are chosen small enough so that B_{\parallel} is essentially constant on each length. The sum must be made over a closed path, and I_{encl} is the total net current enclosed by the closed path.

*** Field Due to a Straight Wire**

We can check Ampère's law by applying it to the simple case of a long straight wire carrying a current I . Let us find the magnitude of B at point A, a distance r from the wire in Fig. 20–29. The magnetic field lines are circles with the wire at their center (as in Fig. 20-8). As the path to be used in Eq. 20-9, we choose a convenient one: a circle of radius r , because at any point on this path, **B** will be tangent to this circle. For any short segment of the circle (Fig. 20–29), \vec{B} will be parallel to that segment, so $B_{\parallel} = B$. Suppose we break the circular path down into 100 segments.[†] Then Ampère's law states that

$$
(B \Delta l)_1 + (B \Delta l)_2 + (B \Delta l)_3 + \cdots + (B \Delta l)_{100} = \mu_0 I
$$

The dots represent all the terms we did not write down. All the segments are the same distance from the wire, so by symmetry we expect B to be the same at each segment. We can then factor out B from the sum:

$$
B(\Delta l_1 + \Delta l_2 + \Delta l_3 + \cdots + \Delta l_{100}) = \mu_0 I.
$$

The sum of the segment lengths Δl is just the circumference of the circle, $2\pi r$.

[†]Actually, Ampère's law is precisely accurate when there is an infinite number of infinitesimally short segments, but that leads into calculus.

FIGURE 20-29 Circular path of

Thus we have

 α r

$$
B = \frac{\mu_0 I}{2\pi r}
$$

 $B(2\pi r) = \mu_0 I,$

This is just Eq. 20–6 for the field near a long straight wire, so Ampère's law agrees with experiment in this case.

A great many experiments indicate that Ampère's law is valid in general. However, it can be used to calculate the magnetic field mainly for simple or symmetric situations. Its importance is that it relates the magnetic field to the current in a direct and mathematically elegant way. Ampère's law is thus considered one of the basic laws of electricity and magnetism. It is valid for any situation where the currents and fields are not changing in time.

* Field Inside a Solenoid

We now use Ampère's law to calculate the magnetic field inside a solenoid, a long coil of wire with many loops or turns, Fig. 20-30. Each loop produces a magnetic field as shown in Fig. 20–9, and the total field inside the solenoid will be the sum of the fields due to each current loop as shown in Fig. 20-30a for a few loops. If the loops of the solenoid are many and are closely spaced, the field inside will be essentially parallel to the axis except at the ends, as shown in Fig. 20–30b. Outside the solenoid, the field lines spread out in space, so the magnetic field is much weaker outside the solenoid than inside. For applying Ampère's law, we choose the path abcd shown in Fig. 20–31 far from either end. We consider this path as made up of four straight segments, the sides of the rectangle: ab, bc, cd, da. Then Ampère's law, Eq. 20–9, becomes

$$
(B_{\parallel} \Delta l)_{ab} + (B_{\parallel} \Delta l)_{bc} + (B_{\parallel} \Delta l)_{cd} + (B_{\parallel} \Delta l)_{da} = \mu_0 I_{encl}.
$$

The first term in the sum on the left will be (nearly) zero since the field outside the solenoid is negligible compared to the field inside. Furthermore, \vec{B} is perpendicular to the segments bc and da, so these terms are zero, too. Thus the left side of our equation above is simply $(B_{\parallel} \Delta l)_{cd} = B_l$, where B is the field inside the solenoid, and l is the length cd. We set Bl equal to μ_0 times the current enclosed

FIGURE 20-31 Cross-sectional view into a solenoid. The magnetic field inside is straight except at the ends. Red dashed lines indicate the path chosen for use in Ampère's law. ⊙ and ⊗ are electric current direction (in the wire loops) out of the page and into the page.

by our chosen rectangular loop: if a current I flows in the wire of the solenoid, the total current enclosed by our path abcd is NI , where N is the number of loops (or turns) our path encircles (five in Fig. 20-31). Thus Ampère's law gives us

$$
Bl = \mu_0 NI
$$

and

 $B = \frac{\mu_0 I N}{I},$ [solenoid] (20-8 repeated)

which we quoted in the previous Section. This is the magnetic field magnitude inside a solenoid. B depends only on the number of loops per unit length, N/l , and the current I . The field does not depend on the position within the solenoid, so B is uniform inside the solenoid. This is strictly true only for an infinite solenoid, but it is a good approximation for real ones for points not close to the ends.

The direction of the magnetic field is found using right-hand-rule-1 (Fig. 20–8c), and is as shown in Fig. 20-31.

B due to straight wire using Ampère's law

FIGURE 20-30 (a) Magnetic field due to several loops of a solenoid. (b) For many closely spaced loops, the field is very nearly uniform.

Magnetic field inside a solenoid

FIGURE 20-32 Calculating the torque on a current loop in a magnetic field \vec{B} . (a) Loop face parallel to \vec{B} field lines; (b) top view; (c) loop makes an angle to \vec{B} , reducing the torque since the lever arm is reduced.

Torque on current loop

Magnetic dipole moment

20-9 Torque on a Current Loop; **Magnetic Moment**

When an electric current flows in a closed loop of wire placed in an external magnetic field, as shown in Fig. 20-32, the magnetic force on the current can produce a torque. This is the principle behind a number of important practical devices, including voltmeters, ammeters, and motors. (We discuss these applications in the next Section.) The interaction between a current and a magnetic field is important in other areas as well, including atomic physics.

Current flows through the loop in Fig. 20–32a, whose face we assume is parallel to \vec{B} and is rectangular. \vec{B} exerts no force and no torque on the horizontal segments of wire because they are parallel to the field and $\sin \theta = 0$ in Eq. 20–1. But the magnetic field does exert a force on each of the vertical sections of wire as shown, \vec{F}_1 and \vec{F}_2 (see also top view, Fig. 20–32b). By right-hand-rule-2 (Fig. 20–11c) the direction of the force on the upward current on the left is in the opposite direction from the equal magnitude force \vec{F}_2 on the descending current on the right. These forces give rise to a net torque that tends to rotate the coil about its vertical axis.

Let us calculate the magnitude of this torque. From Eq. 20–2 (current $\perp \vec{B}$), the force $F = IaB$, where a is the length of the vertical arm of the coil. The lever arm for each force is $b/2$, where b is the width of the coil and the "axis" is at the midpoint. The torques produced by \vec{F}_1 and \vec{F}_2 act in the same direction, so the total torque is the sum of the two torques:

$$
\tau = IaB\frac{b}{2} + IaB\frac{b}{2} = IabB = IAB,
$$

where $A = ab$ is the area of the coil. If the coil consists of N loops of wire, the current is then NI, so the torque becomes

$$
\tau = NIAB.
$$

If the coil makes an angle θ with the magnetic field, as shown in Fig. 20–32c, the forces are unchanged, but each lever arm is reduced from $\frac{1}{2}b$ to $\frac{1}{2}b \sin \theta$. Note that the angle θ is taken to be the angle between \vec{B} and the perpendicular to the face of the coil, Fig. 20–32c. So the torque becomes

$$
\tau = NIAB \sin \theta. \tag{20-10}
$$

This formula, derived here for a rectangular coil, is valid for any shape of flat coil. The quantity *NIA* is called the **magnetic dipole moment** of the coil:

$$
M = NIA \tag{20-11}
$$

and is considered a vector perpendicular to the coil.

EXAMPLE 20-12 Torque on a coil. A circular coil of wire has a diameter of 20.0 cm and contains 10 loops. The current in each loop is 3.00 A, and the coil is placed in a 2.00-T external magnetic field. Determine the maximum and minimum torque exerted on the coil by the field.

APPROACH Equation 20–10 is valid for any shape of coil, including circular loops. Maximum and minimum torque are determined by the angle θ the coil makes with the magnetic field.

SOLUTION The area of one loop of the coil is

 $A = \pi r^2 = \pi (0.100 \text{ m})^2 = 3.14 \times 10^{-2} \text{ m}^2$.

The maximum torque occurs when the coil's face is parallel to the magnetic field, so $\theta = 90^{\circ}$ in Fig. 20–32c, and $\sin \theta = 1$ in Eq. 20–10:

 $\tau = NIAB \sin \theta = (10)(3.00 \text{ A})(3.14 \times 10^{-2} \text{ m}^2)(2.00 \text{ T})(1) = 1.88 \text{ N} \cdot \text{m}.$

The minimum torque occurs if $\sin \theta = 0$, for which $\theta = 0^{\circ}$, and then $\tau = 0$ from Eq. 20-10.

NOTE If the coil is free to turn, it will rotate toward the orientation with $\theta = 0^{\circ}$.

20-10 Applications: Galvanometers, **Motors, Loudspeakers**

* Galvanometer

The basic component of analog meters (those with pointer and dial), including analog ammeters, voltmeters, and ohmmeters, is a galvanometer. We have already seen how these meters are designed (Section 19–8), and now we can examine how the crucial element, a galvanometer, works. As shown in Fig. 20-33, a galvanometer consists of a coil of wire (with attached pointer) suspended in the magnetic field of a permanent magnet. When current flows through the loop of wire, the magnetic field exerts a torque on the loop, as given by Eq. 20–10,

$$
\tau = NIAB \sin \theta.
$$

This torque is opposed by a spring which exerts a torque τ_s approximately proportional to the angle ϕ through which it is turned (Hooke's law). That is,

$$
\tau_{\rm s}=k\phi,
$$

where k is the stiffness constant of the spring. The coil and attached pointer rotate to the angle where the torques balance. When the needle is in equilibrium at rest, the torques are equal: $k\phi = NIAB \sin \theta$, or

$$
\phi = \frac{NIAB\sin\theta}{k}
$$

The deflection of the pointer, ϕ , is directly proportional to the current I flowing in the coil, but also depends on the angle θ the coil makes with \vec{B} . For a useful meter we need ϕ to depend only on the current *I*, independent of θ . To solve this problem, magnets with curved pole pieces are used and the galvanometer coil is wrapped around a cylindrical iron core as shown in Fig. 20-34. The iron tends to concentrate the magnetic field lines so that \vec{B} always points parallel to the face of the coil at the wire outside the core. The force is then always perpendicular to the face of the coil, and the torque will not vary with angle. Thus ϕ will be proportional to I, as required.

Electric Motors

An electric motor changes electric energy into (rotational) mechanical energy. A motor works on the same principle as a galvanometer, except that there is no spring so the coil can rotate continuously in one direction. The coil is larger and is mounted on a large cylinder called the **rotor** or **armature**, Fig. 20–35. Actually, there are several coils, although only one is indicated in the Figure. The armature is mounted on a shaft or axle. When the armature is in the position shown in Fig. 20–35, the magnetic field exerts forces on the current in the loop as shown. However, when the coil, which is rotating clockwise in Fig. 20–35, passes beyond the vertical position, the forces would then act to return the coil back to vertical if the current remained the same. But if the current could somehow be reversed at that critical moment, the forces would reverse, and the coil would continue rotating in the same direction. Thus, alternation of the current is necessary if a motor is to turn continuously in one direction. This can be achieved in a dc motor with the use of commutators and brushes: as shown in Fig. 20–36, the brushes are stationary contacts that rub against the conducting commutators mounted on the motor shaft. At every half revolution, each commutator changes its connection over to the other brush. Thus the current in the coil reverses every half revolution as required for continuous rotation.

FIGURE 20-33 Galvanometer.

FIGURE 20-34 Galvanometer coil wrapped on an iron core.

FIGURE 20-35 Diagram of a simple dc motor.

FIGURE 20-36 The commutator-brush arrangement in a dc motor ensures alternation of the current in the armature to keep rotation continuous. The commutators are attached to the motor shaft and turn with it, whereas the brushes remain stationary.

*SECTION 20-10 Applications: Galvanometers, Motors, Loudspeakers 571

FIGURE 20-37 Motor with many windings.

FIGURE 20-38 Loudspeaker.

PHYSI **APPLIED** The mass spectrometer

FIGURE 20-39 Bainbridge-type mass spectrometer. The magnetic fields B and B' point out of the paper (indicated by the dots).

Most motors contain several coils, called windings, each located in a different place on the armature, Fig. 20-37. Current flows through each coil only during a small part of a revolution, at the time when its orientation results in the maximum torque. In this way, a motor produces a much steadier torque than can be obtained from a single coil.

An ac motor, with ac current as input, can work without commutators since the current itself alternates. Many motors use wire coils to produce the magnetic field (electromagnets) instead of a permanent magnet. Indeed the design of most motors is more complex than described here, but the general principles remain the same.

* Loudspeakers

A **loudspeaker** also works on the principle that a magnet exerts a force on a current-carrying wire. The electrical output of a stereo or TV set is connected to the wire leads of the speaker. The speaker leads are connected internally to a coil of wire, which is itself attached to the speaker cone, Fig. 20–38. The speaker cone is usually made of stiffened cardboard and is mounted so that it can move back and forth freely. A permanent magnet is mounted directly in line with the coil of wire. When the alternating current of an audio signal flows through the wire coil, which is free to move within the magnet, the coil experiences a force due to the magnetic field of the magnet. As the current alternates at the frequency of the audio signal, the coil and attached speaker cone move back and forth at the same frequency, causing alternate compressions and rarefactions of the adjacent air, and sound waves are produced. A speaker thus changes electrical energy into sound energy, and the frequencies and intensities of the emitted sound waves can be an accurate reproduction of the electrical input.

20–11 **Mass Spectrometer**

A mass spectrometer is a device to measure masses of atoms. It is used today not only in physics but also in chemistry, geology, and medicine, often to identify atoms (and their concentration) in given samples. As shown in Fig. 20–39, ions are produced by heating, or by an electric current, in the source or sample S. They pass through slit s_1 and enter a region where there are crossed electric and magnetic fields. Ions follow a straight-line path in this region if the electric force qE (upward on a positive ion) is just balanced by the magnetic force qvB (downward on a positive ion): that is, if $qE = qvB$, or

$$
v = \frac{E}{B}
$$

Only those ions whose speed is $v = E/B$ will pass through undeflected and emerge through slit s_2 . (This arrangement is called a **velocity selector**.) In the semicircular region, after s_2 , there is only a magnetic field, B' , so the ions follow a circular path. The radius of the circular path is found from their mark on film (or detectors) if B' is fixed; if instead r is fixed by the position of a detector, then B' is varied until detection occurs. Newton's second law, $\Sigma F = ma$, applied to an ion moving in a circle under the influence only of the magnetic

572 CHAPTER 20 Magnetism

field B' gives $qvB' = mv^2/r$. Since $v = E/B$, we have

$$
m=\frac{qB'r}{v}=\frac{qBB'r}{E}\cdot
$$

All the quantities on the right side are known or can be measured, and thus m can be determined.

Historically, the masses of many atoms were measured this way. When a pure substance was used, it was sometimes found that two or more closely spaced marks would appear on the film. For example, neon produced two marks whose radii corresponded to atoms of mass 20 and 22 atomic mass units (u). Impurities were ruled out and it was concluded that there must be two types of neon with different masses. These different forms were called isotopes. It was soon found that most elements are mixtures of isotopes, and the difference in mass is due to different numbers of neutrons (discussed in Chapter 30).

EXAMPLE 20-13 Mass spectrometry. Carbon atoms of atomic mass 12.0 u are found to be mixed with another, unknown, element. In a mass spectrometer with fixed B' , the carbon traverses a path of radius 22.4 cm and the unknown's path has a 26.2-cm radius. What is the unknown element? Assume they have the same charge.

APPROACH The carbon and unknown atoms pass through the same electric and magnetic fields. Hence their masses are proportional to the radius of their respective paths (see equation above).

SOLUTION We write a ratio for the masses, using the equation at the top of this page:

$$
\frac{m_x}{m_C} = \frac{qBB'r_x/E}{qBB'r_C/E} = \frac{26.2 \text{ cm}}{22.4 \text{ cm}} = 1.17.
$$

Thus $m_x = 1.17 \times 12.0$ u = 14.0 u. The other element is probably nitrogen (see the periodic table, inside the back cover).

NOTE The unknown could also be an isotope such as carbon-14 $\binom{14}{6}$ C). See Appendix B. Further physical or chemical analysis would be needed.

20-12 Ferromagnetism: Domains and Hysteresis

We saw in Section 20-1 that iron (and a few other materials) can be made into strong magnets. These materials are said to be ferromagnetic.

Sources of Ferromagnetism

Microscopic examination reveals that a magnet is made up of tiny regions known as domains, at most about 1 mm in length or width. Each domain behaves like a tiny magnet with a north and a south pole. In an unmagnetized piece of iron, the domains are arranged randomly, Fig. 20-40a. The magnetic effects of the domains cancel each other out, so this piece of iron is not a magnet. In a magnet, the domains are preferentially aligned in one direction as shown in Fig. 20–40b (downward in this case). A magnet can be made from an unmagnetized piece of iron by placing it in a strong magnetic field. (You can make a needle magnetic, for example, by stroking it with one pole of a strong magnet.) The magnetization direction of domains may actually rotate slightly to be more nearly parallel to an external field, or the borders of domains move so domains with magnetic orientation parallel to the external field grow larger (compare Figs. 20–40a and b). This explains how a magnet can pick up unmagnetized pieces of iron like paper clips. The magnet's field causes a slight alignment of the domains in the unmagnetized object, which becomes a temporary magnet with its north pole facing the south pole of the permanent magnet, and vice versa; thus, attraction results. Similarly, elongated iron filings in a magnetic field

FIGURE 20-40 (a) An unmagnetized piece of iron is made up of domains that are randomly arranged. Each domain is like a tiny magnet; the arrows represent the magnetization direction, with the arrowhead being the N pole. (b) In a magnet, the domains are preferentially aligned in one direction (down in this case), and may be altered in size by the magnetization process.

Isotopes

FIGURE 20-41 Iron filings line up along magnetic field lines due to a permanent magnet.

E start on \bigoplus and end on \bigoplus

FIGURE 20-42 Iron-core toroid.

acquire aligned domains and align themselves to reveal the shape of the magnetic field, Fig. 20–41. See also this Chapter's opening photograph p. 554.

An iron magnet can remain magnetized for a long time, and is referred to as a "permanent magnet." But if you drop a magnet on the floor or strike it with a hammer, you can jar the domains into randomness and the magnet loses some or all of its magnetism. Heating a permanent magnet can also cause loss of magnetism, for raising the temperature increases the random thermal motion of atoms, which tends to randomize the domains. Above a certain temperature known as the **Curie temperature** $(1043 \text{ K}$ for iron), a magnet cannot be made at all.

The striking similarity between the fields produced by a bar magnet and by a loop of electric current or a solenoid (Figs. $20-4b$, $20-9$, and $20-30$) offers a clue that perhaps the magnetic field produced by a current may have something to do with ferromagnetism. According to modern atomic theory, the atoms that make up any material can be roughly visualized as having electrons that orbit around a central nucleus. The electrons are charged, and so constitute an electric current and therefore produce a magnetic field. Electrons themselves produce an additional magnetic field, almost as if they and their electric charge were spinning about their own axes. It is the magnetic field due to electron $spin[†]$ that is believed to produce ferromagnetism in most ferromagnetic materials.

It is believed today that all magnetic fields are caused by electric currents. This means that magnetic field lines always form closed loops, unlike electric field lines which begin on positive charges and end on negative charges.

* Magnetic Permeability

If a piece of iron is placed inside a solenoid to form an electromagnet, the magnetic field increases greatly over that produced by the current in the solenoid coils alone. The total magnetic field **B** is then the sum of two terms, $\mathbf{B} = \mathbf{B}_0 + \mathbf{B}_M$ where \vec{B}_0 is the field due to the current in the wire and \vec{B}_M is the additional field due to the iron (or other magnetic material inserted instead). Often $B_M \gg B_0$. The total field can also be written by replacing the constant μ_0 in Eq. 20-8 $(B = \mu_0 NI/l$ for a solenoid) by the **magnetic permeability** μ , which is characteristic of the magnetic material inside the coil. Then $B = \mu N I/l$. For ferromagnetic materials, μ is much greater than μ_0 . For all other materials, its value is very close to μ_0 .[†] The value of μ , however, is not constant for ferromagnetic materials; it depends on the strength of the "external" field B_0 , as the following experiment shows.

* Hysteresis

To make measurements on magnetic materials, a toroid is used, which is essentially a long solenoid bent into the shape of a donut (Fig. $20-42$), so practically all the lines of \bf{B} remain within the toroid. Consider a toroid with an iron core that is initially unmagnetized and there is no current in the wire loops. Then the current I is slowly increased. The total magnetic field B , which is the sum of the field due to the current alone (B_0) plus the field due to the iron, also increases, but follows the curved line shown in the graph of

³All materials are slightly magnetic. Nonferromagnetic materials fall into two principal classes: (1) paramagnetic materials consist of atoms that have a net magnetic dipole moment which can align slightly with an external field, just as the galvanometer coil in Fig. 20-33 experiences a torque that tends to align it; (2) **diamagnetic** materials have atoms with no net dipole moment, but in the presence of an external field electrons revolving in one direction increase in speed slightly whereas electrons revolving in the opposite direction are reduced in speed; the result is a slight net magnetic effect that opposes the external field.

[†]The name "spin" comes from the early suggestion that the additional magnetic field arises from the electron "spinning" on its axis (as well as "orbiting" the nucleus) to produce the extra field. However, this view of a spinning electron is oversimplified and not valid (see Chapter 28).

FIGURE 20-43 Total magnetic field B in an iron-core toroid as a function of the external field B_0 (B_0 is caused by the current I in the coil).

Fig. 20–43. (Note the different scales: $B \gg B_0$.) At the initial point a, the domains are randomly oriented. As B_0 increases, the domains become more and more aligned until at point b, nearly all are aligned. The iron is said to be approaching saturation. Next, suppose current in the coils is reduced, so the field B_0 decreases. If the current (and B_0) is reduced to zero, point c in Fig. 20–44, the domains do *not* become completely random. Instead, some permanent magnetism remains in the iron core. If the current is increased in the opposite direction, enough domains can be turned around so the total B becomes zero at point d. As the reverse current is increased further, the iron approaches saturation in the opposite direction, point e. Finally, if the current is again reduced to zero and then increased in the original direction, the total field follows the path efgb, again approaching saturation at point b.

Notice that the field did not pass through the origin (point a) in this cycle. The fact that the curve does not retrace itself on the same path is called hysteresis. The curve bcdefgb is called a hysteresis loop. In such a cycle, much energy is transformed to thermal energy (friction) due to realigning of the domains. Note that at points c and f, the iron core is magnetized even though there is no current in the coils. These points correspond to a permanent magnet.

FIGURE 20-44 Hysteresis curve.

Hysteresis

Summary

A magnet has two poles, north and south. The north pole is that end which points toward geographic north when the magnet is freely suspended. Like poles of two magnets repel each other, whereas unlike poles attract.

We can imagine that a magnetic field surrounds every magnet. The SI unit for magnetic field is the tesla (T) .

Electric currents produce magnetic fields. For example, the lines of magnetic field due to a current in a straight wire form circles around the wire, and the field exerts a force on magnets (or currents) near it.

A magnetic field exerts a force on an electric current. For a straight wire of length l carrying a current I , the force has magnitude

$$
F = IlB\sin\theta, \tag{20-1}
$$

where θ is the angle between the magnetic field \vec{B} and the current. The direction of the force is perpendicular to the current-carrying wire and to the magnetic field, and is given by a right-hand rule. Equation 20-1 serves as the definition of magnetic field \vec{B} .

Similarly, a magnetic field exerts a force on a charge q moving with velocity v of magnitude

$$
F = qvB\sin\theta, \tag{20-3}
$$

where θ is the angle between \vec{v} and \vec{B} . The direction of \vec{F} is perpendicular to \vec{v} and to \vec{B} (again a right-hand rule). The path of a charged particle moving perpendicular to a uniform magnetic field is a circle.

The magnitude of the magnetic field produced by a current I in a long straight wire, at a distance r from the wire, is

$$
B = \frac{\mu_0}{2\pi} \frac{I}{r} \tag{20-6}
$$

Two currents exert a force on each other via the magnetic field each produces. Parallel currents in the same direction attract each other; currents in opposite directions repel.

The magnetic field inside a long tightly wound solenoid is

$$
B = \mu_0 NI/l, \tag{20-8}
$$

where N is the number of loops in a length l of coil, and I is the current in each loop.

Summary 575

[*Ampère's law states that around any chosen closed loop path, the sum of each path segment Δl times the component of \vec{B} parallel to the segment equals μ_0 times the current I enclosed by the closed path:

$$
\sum B_{\parallel} \Delta l = \mu_0 I_{\text{encl}}. \tag{20-9}
$$

[*The torque τ on N loops of current I in a magnetic field \vec{B} is

$$
= NIAB \sin \theta. \tag{20-10}
$$

The force or torque exerted on a current-carrying wire by a magnetic field is the basis for operation of many devices, such as meters, motors, and loudspeakers.]

Questions

- 1. A compass needle is not always balanced parallel to the Earth's surface, but one end may dip downward. Explain.
- 2. Draw the magnetic field lines around a straight section of wire carrying a current horizontally to the left.
- 3. In what direction are the magnetic field lines surrounding a straight wire carrying a current that is moving directly away from you?
- 4. A horseshoe magnet is held vertically with the north pole on the left and south pole on the right. A wire passing between the poles, equidistant from them, carries a current directly away from you. In what direction is the force on the wire?
- 5. Will a magnet attract any metallic object, or only those made of iron? (Try it and see.) Why is this so?
- 6. Two iron bars attract each other no matter which ends are placed close together. Are both magnets? Explain.
- 7. The magnetic field due to current in wires in your home can affect a compass. Discuss the effect in terms of currents, including if they are ac or dc.
- 8. If a negatively charged particle enters a region of uniform magnetic field which is perpendicular to the particle's velocity, will the kinetic energy of the particle increase, decrease, or stay the same? Explain your answer. (Neglect gravity and assume there is no electric field.)
- 9. In Fig. 20–45, charged particles move in the vicinity of a current-carrying wire. For each charged particle, the arrow indicates the direction of motion of the particle, and the $+$ or $-$ indicates the sign of the charge. For each of the particles, indicate the

direction of the magnetic force due to the magnetic field produced by the wire.

FIGURE 20-45 Question 9.

10. Three particles, a, b, and c, enter a magnetic field as shown in Fig. 20-46.

[*A mass spectrometer uses electric and magnetic fields to determine the masses of atoms.]

Iron and a few other materials that are ferromagnetic can be made into strong permanent magnets. Ferromagnetic materials are made up of tiny **domains**—each a tiny magnet which are preferentially aligned in a permanent magnet.

[*When iron or another ferromagnetic material is placed in a magnetic field B_0 due to a current, the iron becomes magnetized. When the current is turned off, the material remains magnetized; when the current is increased in the opposite direction, a graph of the total field B versus B_0 is a hysteresis loop, and the fact that the curve does not retrace itself is called hysteresis.]

11. A positively charged particle in a nonuniform magnetic field follows the trajectory shown in Fig. 20-47. Indicate the direction of the magnetic field everywhere in space, assuming the path is always in the plane of the page, and indicate the relative magnitudes of the field in each region.

- 12. Can an iron rod attract a magnet? Can a magnet attract an iron rod? What must you consider to answer these questions?
- 13. Explain why a strong magnet held near a CRT television screen (Section $17-10$) causes the picture to become distorted. Also, explain why the picture sometimes goes completely black where the field is the strongest. [But don't risk damage to your TV by trying this.]
- 14. Suppose you have three iron rods two of which are magnetized but the third is not. How would you determine which two are the magnets without using any additional objects?
- 15. Can you set a resting electron into motion with a magnetic field? With an electric field? Explain.
- 16. A charged particle is moving in a circle under the influence of a uniform magnetic field. If an electric field that points in the same direction as the magnetic field is turned on, describe the path the charged particle will take.
- 17. The force on a particle in a magnetic field is the idea behind electromagnetic pumping. It is used to pump metallic fluids (such as sodium) and to pump blood in artificial heart machines. The basic design is shown in Fig. 20–48. An electric field is applied perpendicular to a blood vessel and to a magnetic field. Explain how ions are caused to move. Do positive and negative ions feel a force in the same direction?

18. A beam of electrons is directed toward a horizontal wire carrying a current from left to right (Fig. 20-49). In what direction is the beam deflected?

- 19. Describe electric and/or magnetic fields that surround a moving electric charge.
- 20. A charged particle moves in a straight line through a particular region of space. Could there be a nonzero magnetic field in this region? If so, give two possible situations.
- 21. If a moving charged particle is deflected sideways in some region of space, can we conclude, for certain, that $\vec{B} \neq 0$ in that region? Explain.
- 22. In a particular region of space there is a uniform magnetic field \vec{B} . Outside this region, $B = 0$. Can you inject an electron from outside into the field perpendicularly so that it will move in a closed circular path in the field? What if the electron is injected near the center?
- 23. How could you tell whether moving electrons in a certain region of space are being deflected by an electric field or by a magnetic field (or by both)?
- 24. How can you make a compass without using iron or other ferromagnetic material?
- 25. Two long wires carrying equal currents I are at right angles to each other, but don't quite touch. Describe the magnetic force one exerts on the other.
- 26. A horizontal current-carrying wire, free to move in Earth's gravitational field, is suspended directly above a second, parallel, current-carrying wire. (a) In what direction is the current in the lower wire? (b) Can the upper wire be held in stable equilibrium due to the magnetic force of the lower wire? Explain.
- 27. Why will either pole of a magnet attract an unmagnetized piece of iron?
- 28. An unmagnetized nail will not attract an unmagnetized paper clip. However, if one end of the nail is in contact with a magnet, the other end *will* attract a paper clip. Explain.
- * 29. Two ions have the same mass, but one is singly ionized and the other is doubly ionized. How will their positions on the film of a mass spectrometer (Fig. 20-39) differ?
- 30. What would be the effect on B inside a long solenoid if (a) the diameter of all the loops was doubled, (b) the spacing between loops was doubled, or (c) the solenoid's length was doubled along with a doubling in the total number of loops?
- 31. A type of magnetic switch similar to a solenoid is a relay (Fig. 20–50). A relay is an electromagnet (the iron rod inside the coil does not move) which, when activated, attracts a piece of iron on a pivot. Design a relay to close an electrical switch. A relay is used when you need to switch on a circuit carrying a very large current but you do not want that large current flowing through the main switch. For example, the starter switch of a car is connected to a relay so that the large current needed for the starter doesn't pass to the dashboard switch.

FIGURE 20-50 Ouestion 31.

Problems

20-3 Force on Electric Current in Magnetic Field

- 1. (I) (a) What is the magnitude of the force per meter of length on a straight wire carrying an 8.40-A current when perpendicular to a 0.90-T uniform magnetic field? (b) What if the angle between the wire and field is 45.0° ?
- 2. (I) Calculate the magnitude of the magnetic force on a 160-m length of straight wire stretched between two towers carrying a 150-A current. The Earth's magnetic field of 5.0×10^{-5} T makes an angle of 65° with the wire.
- 3. (I) How much current is flowing in a wire 4.80 m long if the maximum force on it is 0.750 N when placed in a uniform 0.0800-T field?
- 4. (II) A 1.5-m length of wire carrying 4.5 A of current is oriented horizontally. At that point on the Earth's surface, the dip angle of the Earth's magnetic field makes an angle of 38° to the wire. Estimate the magnitude of the magnetic force on the wire due to the Earth's magnetic field of 5.5×10^{-5} T at this point.
- 5. (II) The force on a wire carrying 8.75 A is a maximum of 1.28 N when placed between the pole faces of a magnet. If the pole faces are 55.5 cm in diameter, what is the approximate strength of the magnetic field?
- 6. (II) The magnetic force per meter on a wire is measured to be only 35% of its maximum possible value. Sketch the relationship of the wire and the field if the force had been a maximum, and sketch the relationship as it actually is, calculating the angle between the wire and the magnetic field.
- (II) The force on a wire is a maximum of 6.50×10^{-2} N 7. when placed between the pole faces of a magnet. The current flows horizontally to the right and the magnetic field is vertical. The wire is observed to "jump" toward the observer when the current is turned on. (a) What type of magnetic pole is the top pole face? (b) If the pole faces have a diameter of 10.0 cm, estimate the current in the wire if the field is 0.16 T. (c) If the wire is tipped so that it makes an angle of 10.0° with the horizontal, what force will it now feel?
- 8. (II) Suppose a straight 1.00-mm-diameter copper wire could just "float" horizontally in air because of the force due to the Earth's magnetic field \vec{B} , which is horizontal, perpendicular to the wire, and of magnitude 5.0×10^{-5} T. What current would the wire carry? Does the answer seem feasible? Explain briefly.

20-4 Force on Charge Moving in Magnetic Field

- 9. (I) Alpha particles of charge $q = +2e$ and mass $m =$ 6.6×10^{-27} kg are emitted from a radioactive source at a speed of 1.6×10^7 m/s. What magnetic field strength would be required to bend them into a circular path of radius $r = 0.25$ m?
- 10. (I) Determine the magnitude and direction of the force on an electron traveling 8.75×10^5 m/s horizontally to the east in a vertically upward magnetic field of strength 0.75 T.
- 11. (I) Find the direction of the force on a negative charge for each diagram shown in Fig. 20-51, where \vec{v} (green) is the velocity of the charge and \vec{B} (blue) is the direction of the magnetic field. $(\otimes$ means the vector points inward. © means it points outward, toward vou.)

FIGURE 20-51 Problem 11.

12. (I) Determine the direction of \vec{B} for each case in Fig. 20–52, where \vec{F} represents the maximum magnetic force on a positively charged particle moving with velocity \vec{v} .

- 13. (I) An electron is projected vertically upward with a speed of 1.70×10^6 m/s into a uniform magnetic field of 0.350 T that is directed horizontally away from the observer. Describe the electron's path in this field.
- 14. (II) A 5.0-MeV (kinetic energy) proton enters a 0.20-T field, in a plane perpendicular to the field. What is the radius of its path?
- 15. (II) An electron experiences the greatest force as it travels 2.9×10^{6} m/s in a magnetic field when it is moving northward. The force is upward and of magnitude 7.2×10^{-13} N. What are the magnitude and direction of the magnetic field?
- 16. (II) What is the velocity of a beam of electrons that go undeflected when passing through perpendicular electric and magnetic fields of magnitude 8.8×10^3 V/m and 3.5×10^{-3} T, respectively? What is the radius of the electron orbit if the electric field is turned off?
- 17. (II) A doubly charged helium atom whose mass is 6.6×10^{-27} kg is accelerated by a voltage of 2100 V. (a) What will be its radius of curvature if it moves in a plane perpendicular to a uniform 0.340-T field? (b) What is its period of revolution?
- **18.** (II) A proton (mass m_p), a deuteron $(m = 2m_p, Q = e)$, and an alpha particle $(m = 4m_p, Q = 2e)$ are accelerated by the same potential difference V and then enter a uniform magnetic field \vec{B} , where they move in circular paths perpendicular to \vec{B} . Determine the radius of the paths for the deuteron and alpha particle in terms of that for the proton.

19. (II) Show that the time T required for a particle of charge q moving with constant speed v to make one circular revolution in a uniform magnetic field \vec{B} ($\perp \vec{v}$) is

$$
T = \frac{2\pi m}{aB}
$$

[*Hint*: see Example 20–5 and Chapter 5.]

- 20. (II) A particle of charge q moves in a circular path of radius r in a uniform magnetic field B . Show that its momentum is $p = qBr$.
- 21. (II) A particle of mass m and charge q moves in a circular path in a magnetic field B . Show that its kinetic energy is proportional to r^2 , the square of the radius of curvature of its path.
- 22. (II) Show that the angular momentum of the particle in Problem 21 is $L = qBr^2$ about the center of the circle.
- 23. (III) A $3.40-g$ bullet moves with a speed of 160 m/s perpendicular to the Earth's magnetic field of 5.00×10^{-5} T. If the bullet possesses a net charge of 13.5×10^{-9} C, by what distance will it be deflected from its path due to the Earth's magnetic field after it has traveled 1.00 km?
- 24. (III) Suppose the Earth's magnetic field at the equator has magnitude 0.40×10^{-4} T and a northerly direction at all points. Estimate the speed a singly ionized uranium ion ($m = 238$ u, $q = e$) would need to circle the Earth 5.0 km above the equator. Can you ignore gravity?
- 25. (III) A proton moving with speed $v = 2.0 \times 10^5$ m/s in a field-free region abruptly enters an essentially uniform magnetic field $B = 0.850 \text{ T } (\vec{B} \perp \vec{v}).$ If the proton enters the magnetic field region at a 45° angle as shown in Fig. 20-53, (a) at what angle does it leave, and (b) at what distance x does it exit the field?

FIGURE 20-53 Problem 25.

20-5 and 20-6 Magnetic Field of Straight Wire, Force **Between Two Wires**

- 26. (I) A jumper cable used to start a stalled vehicle carries a 65-A current. How strong is the magnetic field 6.0 cm away from it? Compare to the Earth's magnetic field.
- 27. (I) If an electric wire is allowed to produce a magnetic field no larger than that of the Earth (0.55×10^{-4} T) at a distance of 25 cm, what is the maximum current the wire can carry?
- 28. (I) In Fig. 20–54, a long straight wire carries current I out of the page toward you. Indicate, with appropriate arrows, the

- 29. (I) A vertical straight wire carrying an upward 24-A current exerts an attractive force per unit length of 8.8×10^{-4} N/m on a second parallel wire 7.0 cm away. What current (magnitude and direction) flows in the second wire?
- 30. (I) Determine the magnitude and direction of the force between two parallel wires 35 m long and 6.0 cm apart, each carrying 25 A in the same direction.
- 31. (II) An experiment on the Earth's magnetic field is being carried out 1.00 m from an electric cable. What is the maximum allowable current in the cable if the experiment is to be accurate to $\pm 1.0\%$?
- 32. (II) A power line carries a current of 95 A along the tops of 8.5-m-high poles. What is the magnitude of the magnetic field produced by this wire at the ground? How does this compare with the Earth's field of about $\frac{1}{2}$ G?
- 33. (II) Two long thin parallel wires 13.0 cm apart carry 25-A currents in the same direction. Determine the magnetic field at point P, 12.0 cm from one wire and 5.0 cm from the other (Fig. 20-55).

- **FIGURE 20-55** Problem 33.
- 34. (II) A horizontal compass is placed 18 cm due south from a straight vertical wire carrying a 35-A current downward. In what direction does the compass needle point at this location? Assume the horizontal component of the Earth's field at this point is 0.45×10^{-4} T and the magnetic declination is 0°.
- 35. (II) A long horizontal wire carries 22.0 A of current due north. What is the net magnetic field 20.0 cm due west of the wire if the Earth's field there points north but downward. 37° below the horizontal, and has magnitude 5.0×10^{-5} T?
- 36. (II) A straight stream of protons passes a given point in space at a rate of 1.5×10^9 protons/s. What magnetic field do they produce 2.0 m from the beam?
- 37. (II) Determine the magnetic field midway between two long straight wires 2.0 cm apart in terms of the current I in one when the other carries 15 A. Assume these currents are (a) in the same direction, and (b) in opposite directions.
- 38. (II) A long pair of wires conducts 25.0 A of dc current to, and from, an instrument. If the insulated wires are of negligible diameter but are 2.8 mm apart, what is the magnetic field 10.00 cm from their midpoint, in their plane (Fig. 20-56)? Compare to the magnetic field of the Earth.

- $39.$ (II) A third wire is placed in the plane of the two wires shown in Fig. 20-56, parallel and just to the right. If it carries 25.0 A upward, what force per meter of length does it exert on each of the other two wires? Assume it is 2.8 mm from the nearest wire, center to center.
- 40. (II) A compass needle points 23° E of N outdoors. However, when it is placed 12.0 cm to the east of a vertical wire inside a building, it points 55° E of N. What are the magnitude and direction of the current in the wire? The Earth's field there is 0.50 \times 10⁻⁴ T and is horizontal.
- 41. (II) A rectangular loop of wire lies in the same plane as a straight wire, as shown in Fig. 20-57. There is a current of 2.5 A in both wires. Determine the magnitude and direction of the net force on the loop.

FIGURE 20-57 Problem 41.

42. (II) A long horizontal wire carries a current of 48 A. A second wire, made of 2.5-mm-diameter copper wire and parallel to the first, is kept in suspension magnetically 15 cm below (Fig. $20-58$). (a) Determine the magnitude and direction of the current in the lower wire. (b) Is the lower wire in stable equilibrium? (c) Repeat parts (a) and (b) if the second wire is suspended 15 cm *above* the first due to the latter's field.

FIGURE 20-58 Problem 42.

43. (II) Two long wires are oriented so that they are perpendicular to each other. At their closest, they are 20.0 cm apart (Fig. 20-59). What is the magnitude of the magnetic field at a point midway between them if the top one carries a current of 20.0 A and the bottom one carries 5.0 A?

$$
I_T = 20.0 \text{ A}
$$

10.0 cm

$$
B = ? \begin{array}{c} \bullet \\ \bullet \\ 10.0 \text{ cm} \\ \bullet \end{array}
$$

10.0 cm
Bottom wire
$$
I_B = 5.0 \text{ A}
$$

FIGURE 20-59 Problem 43.

Problems 579

- 44. (II) Two long straight parallel wires are 15 cm apart. Wire A carries 2.0 A current. Wire B's current is 4.0 A in the same direction. (a) Determine the magnetic field magnitude due to wire A at the position of wire B. (b) Determine the magnetic field due to wire B at the position of wire A. (c) Are these two magnetic fields equal and opposite? Why or why not? (d) Determine the force on wire A due to wire B, and the force on wire B due to wire A. Are these two forces equal and opposite? Why or why not?
- 45. (II) Three long parallel wires are 3.8 cm from one another. (Looking along them, they are at three corners of an equilateral triangle.) The current in each wire is 8.00 A, but its direction in wire M is opposite to that in wires N and P (Fig. 20-60). Determine the magnetic force per unit length on each wire due to the other two.

FIGURE 20-60 Problems 45, 46, and 74.

- 46. (II) In Fig. 20–60, determine the magnitude and direction of the magnetic field at the midpoint of the side of the triangle between wire M and wire N.
- 47. (II) Let two long parallel wires, a distance d apart, carry equal currents I in the same direction. One wire is at $x = 0$, the other is at $x = d$, Fig. 20–61. Determine **B** along the x axis between the wires as a function of x .

FIGURE 20-61 Problem 47.

20-7 Solenoids and Electromagnets

- 48. (I) A thin 12-cm-long solenoid has a total of 420 turns of wire and carries a current of 2.0 A. Calculate the field inside near the center.
- 49. (I) A 30.0-cm long solenoid 1.25 cm in diameter is to produce a field of 0.385 T at its center. How much current should the solenoid carry if it has 975 turns of the wire?
- 50. (II) A 550-turn solenoid is 15 cm long. The current in it is 33 A. A 3.0-cm-long straight wire cuts through the center of the solenoid, along a diameter. This wire carries a 22-A current downward (and is connected by other wires that don't concern us). What is the force on this wire assuming the solenoid's field points due east?

51. (III) You have 1.0 kg of copper and want to make a practical solenoid that produces the greatest possible magnetic field for a given voltage. Should you make your copper wire long and thin, short and fat, or something else? Consider other variables, such as solenoid diameter, length, and so on.

* 20-8 Ampère's Law

*52. (II) A toroid is a solenoid in the shape of a circle (Fig. 20-62). Use Ampère's law along the circular path, shown dashed in Fig. 20-62a, to determine that the magnetic field (a) inside the toroid is $B = \mu_0 NI/2\pi R$, where N is the total number of turns, and (b) outside the toroid is $B = 0$. (c) Is the field inside a toroid uniform like a solenoid's? If not, how does it vary?

FIGURE 20-62 Problem 52. (a) A toroid. (b) A section of the toroid showing direction of the current for three loops: ⊙ means current toward you, and \otimes means current away from you.

*53. (III) (a) Use Ampère's law to show that the magnetic field between the conductors of a coaxial cable (Fig. 20-63) is $B = \mu_0 I/2\pi r$ if r is greater than the radius of the inner wire and less than the radius of the outer cylindrical braid. (b) Show that $B = 0$ outside the coaxial cable.

FIGURE 20-63 Coaxial cable. Problem 53.

* 20-9 and 20-10 Torque on Current Loop, Applications

*54. (I) A single square loop of wire 22.0 cm on a side is placed with its face parallel to the magnetic field between the pole pieces of a large magnet. When 6.30 A flows in the coil, the torque on it is $0.325 \text{ m} \cdot \text{N}$. What is the magnetic field strength?

- * 55. (I) A galvanometer needle deflects full scale for a 53.0- μ A current. What current will give full-scale deflection if the magnetic field weakens to 0.860 of its original value?
- $*56$. (I) If the restoring spring of a galvanometer weakens by 25% over the vears, what current will give full-scale deflection if it originally required $36 \mu A$?
- $*57.$ (I) If the current to a motor drops by 12%, by what factor does the output torque change?
- $*$ 58. (II) Show that the magnetic dipole moment M of an electron orbiting the proton nucleus of a hydrogen atom is related to the orbital angular momentum L of the electron by

$$
M = \frac{e}{2m} L
$$

* 59. (II) A circular coil 16.0 cm in diameter and containing nine loops lies flat on the ground. The Earth's magnetic field at this location has magnitude 5.50×10^{-5} T and points into the Earth at an angle of 56.0° below a line pointing due north. If a 7.20-A clockwise current passes through the coil, (a) determine the torque on the coil, and (b) which edge of the coil rises up: north, east, south, or west?

* 20-11 Mass Spectrometer

- $*60.$ (I) Protons move in a circle of radius 5.10 cm in a 0.566-T magnetic field. What value of electric field could make their paths straight? In what direction must it point?
- * 61. (I) In a mass spectrometer, germanium atoms have radii of curvature equal to 21.0, 21.6, 21.9, 22.2, and 22.8 cm. The largest radius corresponds to an atomic mass of 76 u. What are the atomic masses of the other isotopes?

General Problems

- 67. Protons with momentum 4.8×10^{-16} kg·m/s are magnetically steered clockwise in a circular path 2.0 km in diameter at Fermi National Accelerator Laboratory in Illinois. Determine the magnitude and direction of the field in the magnets surrounding the beam pipe.
- 68. A proton and an electron have the same kinetic energy upon entering a region of constant magnetic field. What is the ratio of the radii of their circular paths?
- 69. The power cable for an electric trolley (Fig. 20–64) carries a horizontal current of 330 A toward the east. The Earth's magnetic field has a strength 5.0×10^{-5} T and makes an angle of dip of 22° at this location. Calculate the magnitude and direction of the magnetic force on a 15-m length of this cable.

70. Calculate the force on an airplane which has acquired a net charge of $1550 \mu C$ and moves with a speed of 120 m/s perpendicular to the Earth's magnetic field of 5.0×10^{-5} T.

- * 62. (II) Suppose the electric field between the electric plates in the mass spectrometer of Fig. 20–39 is 2.48 \times 10⁴ V/m and the magnetic fields $B = B' = 0.68$ T. The source contains carbon isotopes of mass numbers 12, 13, and 14 from a long-dead piece of a tree. (To estimate atomic masses, multiply by 1.67×10^{-27} kg.) How far apart are the lines formed by the singly charged ions of each type on the photographic film? What if the ions were doubly charged?
- * 63. (II) A mass spectrometer is being used to monitor air pollutants. It is difficult, however, to separate molecules with nearly equal mass such as CO (28.0106 u) and N_2 (28.0134 u). How large a radius of curvature must a spectrometer have if these two molecules are to be separated on the film by 0.50 mm?
- *64. (II) One form of mass spectrometer accelerates ions by a voltage V before they enter a magnetic field B . The ions are assumed to start from rest. Show that the mass of an ion is $m = qB^2R^2/2V$, where R is the radius of the ions' path in the magnetic field and q is their charge.

20-12 Ferromagnetism, Hysteresis

- * 65. (I) A long thin solenoid has 430 loops of wire per meter, and a 25-A current flows through the wire. If the permeability of the iron is $3000\mu_0$, what is the total field B inside the solenoid?
- $*66.$ (II) An iron-core solenoid is 38 cm long and 1.8 cm in diameter, and has 640 turns of wire. The magnetic field inside the solenoid is 2.2 T when 48 A flows in the wire. What is the permeability μ at this high field strength?
- 71. Near the equator, the Earth's magnetic field points almost horizontally to the north and has magnitude $B = 0.50 \times 10^{-4}$ T. What should be the magnitude and direction for the velocity of an electron if its weight is to be exactly balanced by the magnetic force?
- 72. A doubly charged helium atom, whose mass is 6.6×10^{-27} kg, is accelerated by a voltage of 2400 V. (a) What will be its radius of curvature in a uniform 0.240 -T field? (b) What is its period of revolution?
- 73. A sort of "projectile launcher" is shown in Fig. 20-65. A large current moves in a closed loop composed of fixed rails, a power supply, and a very light, almost frictionless bar touching the rails. A magnetic field is perpendicular to the plane of the circuit. If the bar has a length $L = 22$ cm, a mass of 1.5 g, and is placed in a field of 1.7 T, what constant current flow is needed to accelerate the bar from rest to 28 m/s in a distance of 1.0 m? In what direction must the magnetic field point?

FIGURE 20-65 Problem 73.

74. In Fig. 20–60 the top wire is 1.00-mm-diameter copper wire and is suspended in air due to the two magnetic forces from the bottom two wires. The current flow through the two bottom wires is 95 A in each. Calculate the required current flow in the suspended wire.

75. Two stiff parallel wires a distance *l* apart in a horizontal plane act as rails to support a light metal rod of mass m (perpendicular to each rail), Fig. 20-66. A magnetic field \vec{B} , directed vertically upward (outward in the diagram), acts throughout. At $t = 0$, wires connected to the rails are connected to a constant current source and a current I begins to flow through the system. Determine the speed of the rod, which starts from rest at $t = 0$, as a function of time (a) assuming no friction between the rod and the rails, and (b) if the coefficient of friction is μ_k . (c) Does the rod move east or west if the current through it heads north?

FIGURE 20-66 Looking down on a rod sliding on rails. Problem 75.

- 76. Estimate the approximate maximum deflection of the electron beam near the center of a TV screen due to the Earth's 5.0×10^{-5} T field. Assume the CRT screen (Section 17-10) is 22 cm from the electron gun, where the electrons are accelerated (a) by 2.0 kV , or (b) by 30 kV . Note that in color TV sets, the CRT beam must be directed accurately to within less than 1 mm in order to strike the correct phosphor. Because the Earth's field is significant here, mu-metal shields are used to reduce the Earth's field in the CRT.
- 77. The cyclotron (Fig. $20-67$) is a device used to accelerate elementary particles such as protons to high speeds. Particles starting at point A with some initial velocity travel in circular orbits in the magnetic field B . The particles are accelerated to higher speeds each time they pass through the gap between the metal "dees," where there is an electric field E. (There is no electric field inside the hollow metal dees.) The electric field changes direction each half-cycle, owing to an ac voltage $V = V_0 \sin 2\pi f t$, so that the particles are increased in speed at each passage through the gap. (a) Show that the frequency f of the voltage must be $f = Bq/2\pi m$, where q is the charge on the particles and m their mass. (b) Show that the kinetic energy of the particles increases by $2qV_0$ each revolution, assuming that the gap is small. (c) If the radius of the cyclotron is 2.0 m and the magnetic field strength is 0.50 T, what will be the maximum kinetic energy of accelerated protons in MeV?

582 CHAPTER 20 Magnetism 78. Four very long straight parallel wires, located at the corners of a square of side *l*, carry equal currents I_0 perpendicular to the page as shown in Fig. 20-68. Determine the magnitude and direction of \vec{B} at the center C of the square.

FIGURE 20-68 Problem 78.

79. Magnetic fields are very useful in particle accelerators for "beam steering"; that is, the magnetic fields can be used to change the beam's direction without altering its speed (Fig. 20-69). Show how this works with a beam of protons. What happens to protons that are not moving with the speed that the magnetic field is designed for? If the field extends over a region 5.0 cm wide and has a magnitude of 0.33 T, by approximately what angle will a beam of protons traveling at 1.0×10^7 m/s be bent?

80. The magnetic field B at the center of a circular coil of wire carrying a current I (as in Fig. 20-9) is

$$
B = \frac{\mu_0 NI}{2r},
$$

where N is the number of loops in the coil and r is its radius. Suppose that an electromagnet uses a coil 1.2 m in diameter made from square copper wire 1.6 mm on a side. The power supply produces $120V$ at a maximum power output of 4.0 kW . (a) How many turns are needed to run the power supply at maximum power? (b) What is the magnetic field strength at the center of the coil? (c) If you use a greater number of turns and this same power supply (so the voltage remains at 120 V), will a greater magnetic field strength result? Explain.

- 81. Near the Earth's poles the magnetic field is about 1 G $(1 \times 10^{-4} \text{ T})$. Imagine a simple model in which the Earth's field is produced by a single current loop around the equator. Roughly estimate the current this loop would carry. [*Hint*: use the formula given in Problem 80.]
- 82. You want to get an idea of the magnitude of magnetic fields produced by overhead power lines. You estimate that the two wires are each about 30 m above the ground and are about 3 m apart. The local power company tells you that the lines operate at 10 kV and provide a maximum of 40 MW to the local area. Estimate the maximum magnetic field you might experience walking under these power lines, and compare to the Earth's field. [For an ac current, values are rms, and the magnetic field will be changing.]
- 83. (a) What value of magnetic field would make a beam of electrons, traveling to the right at a speed of 4.8×10^6 m/s, go undeflected through a region where there is a uniform electric field of $10,000 \text{ V/m}$ pointing vertically up? (b) What is the direction of the magnetic field if it is known to be perpendicular to the electric field? (c) What is the frequency of the circular orbit of the electrons if the electric field is turned off?
- 84. A proton follows a spiral path through a gas in a magnetic field of 0.010 T, perpendicular to the plane of the spiral, as shown in Fig. 20-70. In two successive loops, at points P and Q, the radii are 10.0 mm and 8.5 mm, respectively. Calculate the change in the kinetic energy of the proton as it travels from P to Q.

FIGURE 20-70 Problem 84.

- 85. A 32-cm-long solenoid, 1.8 cm in diameter, is to produce a 0.30-T magnetic field at its center. If the maximum current is 5.7 A, how many turns must the solenoid have?
- 86. Two long straight aluminum wires, each of diameter 0.50 mm, carry the same current but in opposite directions. They are suspended by 0.50-m-long strings as shown in Fig. 20-71. If the suspension strings make an angle of 3.0° with the vertical, what is the current in the wires?

FIGURE 20-71 Problem 86.

87. An electron enters a uniform magnetic field $B = 0.23$ T at a 45 $^{\circ}$ angle to **B**. Determine the radius r and pitch p (distance between loops) of the electron's helical path assuming its speed is 3.0×10^6 m/s. See Fig. 20-72.

FIGURE 20-72 Problem 87.

Answers to Exercises

- A: Near the poles, where the field lines are closer together.
- B: Counterclockwise.
- $C: 0.15 N.$
- D: Zero.
- E: Negative; the direction of the helical path would be reversed.
- F: 2.0 cm.

One of the great laws of physics is Faraday's law of induction, which says that a changing magnetic flux produces an induced emf. This photo shows a bar magnet moving inside a coil of wire, and the galvanometer registers an induced current. This phenomenon of electromagnetic induction is the basis for many practical devices, from generators to alternators to transformers, tape recording, and computer memory.

CHAPTER 21

Electromagnetic Induction and Faraday's Law

n Chapter 20, we discussed two ways in which electricity and magnetism are related: (1) an electric current produces a magnetic field; and (2) a magnetic field exerts a force on an electric current or moving electric charge. These discoveries were made in 1820–1821. Scientists then began to wonder: if electric currents produce a magnetic field, is it possible that a magnetic field can produce an electric current? Ten years later the American Joseph Henry $(1797-1878)$ and the Englishman Michael Faraday $(1791-1867)$ independently found that it was possible. Henry actually made the discovery first. But Faraday published his results earlier and investigated the subject in more detail. We now discuss this phenomenon and some of its world-changing applications such as the electric generator.

-1 Induced EMF

In his attempt to produce an electric current from a magnetic field, Faraday used an apparatus like that shown in Fig. 21-1. A coil of wire, X, was connected to a battery. The current that flowed through X produced a magnetic field that was intensified by the iron core around which the wire was wrapped. Faraday hoped that a strong steady current in X would produce a great enough magnetic

FIGURE 21-1 Faraday's experiment to induce an emf.

field to produce a current in a second coil Y which shared the same iron core. This second circuit, Y, contained a galvanometer to detect any current but contained no battery. He met no success with constant currents. But the longsought effect was finally observed when Faraday noticed the galvanometer in circuit Y deflect strongly at the moment he closed the switch in circuit X. And the galvanometer deflected strongly in the opposite direction when he opened the switch in X. A constant current in X produced a constant magnetic field which produced no current in Y. Only when the current in X was starting or stopping was a current produced in Y.

Faraday concluded that although a constant magnetic field produces no current in a conductor, a *changing* magnetic field can produce an electric current. Such a current is called an **induced current**. When the magnetic field through coil Y changes, a current occurs in Y as if there were a source of emf in circuit Y. We therefore say that

a changing magnetic field induces an emf.

Faraday did further experiments on electromagnetic induction, as this phenomenon is called. For example, Fig. 21-2 shows that if a magnet is moved quickly into a coil of wire, a current is induced in the wire. If the magnet is quickly removed, a current is induced in the opposite direction $(\vec{B}$ through the coil decreases). Furthermore, if the magnet is held steady and the coil of wire is moved toward or away from the magnet, again an emf is induced and a current flows. Motion or change is required to induce an emf. It doesn't matter whether the magnet or the coil moves. It is their *relative motion* that counts.

 \bullet CAUTION Changing \vec{B} , not \vec{B} itself, *induces* current

Changing \vec{B} induces an emf

CAUTION Relative motion-magnet or coil moving induces current

FIGURE 21-2 (a) A current is induced when a magnet is moved toward a coil, momentarily increasing the magnetic field through the coil. (b) The induced current is opposite when the magnet is moved away from the coil $(\vec{B}$ decreases). Note that the galvanometer zero is at the center of the scale and the needle deflects left or right, depending on the direction of the current. In (c) , no current is induced if the magnet does not move relative to the coil. It is the relative motion that counts here: the magnet can be held steady and the coil moved, which also induces an emf.

FIGURE 21-3 Determining the flux through a flat loop of wire. This loop is square, of side l and area $A = l^2$.

FIGURE 21-4 Magnetic flux Φ_B is proportional to the number of lines of \vec{B} that pass through the loop.

FIGURE $21-5$ Example $21-1$.

21-2 Faraday's Law of Induction; Lenz's Law

Faraday investigated quantitatively what factors influence the magnitude of the emf induced. He found first of all that the more rapidly the magnetic field changes, the greater the induced emf in a loop of wire. But the emf is not simply proportional to the rate of change of the magnetic field, \vec{B} ; it depends also on the loop's area and angle. That is, the emf is proportional to the rate of change of the **magnetic flux**, Φ_B , through the loop. Magnetic flux for a uniform magnetic field through a loop of area A is defined as

$$
\Phi_B = B_\perp A = BA \cos \theta. \qquad [B \text{ uniform}] \quad (21-1)
$$

Here B_1 is the component of the magnetic field \vec{B} perpendicular to the face of the loop, and θ is the angle between **B** and a line perpendicular to the face of the loop. These quantities are shown in Fig. $21-3$ for a square loop of side l whose area is $A = l^2$. When the face of the loop is parallel to \vec{B} , $\theta = 90^\circ$ and $\Phi_B = 0$. When **B** is perpendicular to the loop, $\theta = 0^{\circ}$, and

$$
\Phi_B = BA.
$$
 [uniform $\vec{B} \perp$ loop face]

As we saw in Chapter 20, the lines of \vec{B} (like lines of \vec{E}) can be drawn such that the number of lines per unit area is proportional to the field strength. Then the flux Φ_B can be thought of as being proportional to the *total number of lines* passing through the area enclosed by the loop. This is illustrated in Fig. 21-4, where the loop is viewed from the side (on edge). For $\theta = 90^{\circ}$, no magnetic field lines pass through the loop and $\Phi_B = 0$, whereas Φ_B is a maximum when $\theta = 0^\circ$. The unit of magnetic flux is the tesla-meter²; this is called a **weber**: $1 \text{ Wb} = 1 \text{ T} \cdot \text{m}^2$.

CONCEPTUAL EXAMPLE 21-1 Determining flux. A square loop of wire encloses area A_1 as shown in Fig. 21–5. A uniform magnetic field \vec{B} perpendicular to the loop extends over the area A_2 . What is the magnetic flux through the loop A_1 ?

RESPONSE We assume that the magnetic field is zero outside the area A_2 . The total magnetic flux through area A_1 is the flux through area A_2 , which by Eq. 21-1 for a uniform field is BA_2 , plus the flux through the remaining area (= $A_1 - A_2$), which is zero because $B = 0$. So the total flux is $\Phi_B = BA_2 + 0(A_1 - A_2) = BA_2$. It is *not* equal to BA_1 because **B** is not uniform over A_1 .

EXAMPLE 21-2 Calculate the flux. A square loop of wire 10.0 cm on a side is in a 1.25 -T magnetic field B . What are the maximum and minimum values of flux that can pass through the loop?

APPROACH The flux is given by Eq. 21–1. It is a maximum for $\theta = 0^{\circ}$, which occurs when the plane of the loop is perpendicular to \vec{B} . The minimum value occurs when $\theta = 90^{\circ}$ and the plane of the loop is aligned with **B**. **SOLUTION** From Eq. $21-1$, the maximum value is

$$
\Phi_B = BA \cos \theta = (1.25 \text{ T})(0.100 \text{ m})(0.100 \text{ m}) \cos 0^\circ = 0.0125 \text{ Wb}.
$$

The minimum value is 0 Wb when $\theta = 90^{\circ}$ and $\cos 90^{\circ} = 0$.

EXERCISE A Find the flux in Example $21-2$ when the perpendicular to the coil makes a 35 $^{\circ}$ angle with **B**.

With our definition of flux, Eq. 21–1, we can now write down the results of Faraday's investigations. If the flux through a loop of wire changes by an amount $\Delta \Phi_B$ over a very brief time interval Δt , the induced emf at this instant is

$$
\mathscr{E} = -\frac{\Delta \Phi_B}{\Delta t}.
$$
 [1 loop] (21-2a)

This fundamental result is known as Faraday's law of induction, and it is one of the basic laws of electromagnetism.

FIGURE 21-3 Determining the flux through a flat loop of wire. This loop is square, of side l and area $A = l^2$.

FIGURE 21-4 Magnetic flux Φ_B is proportional to the number of lines of \vec{B} that pass through the loop.

FIGURE $21-5$ Example $21-1$.

21-2 Faraday's Law of Induction; Lenz's Law

Faraday investigated quantitatively what factors influence the magnitude of the emf induced. He found first of all that the more rapidly the magnetic field changes, the greater the induced emf in a loop of wire. But the emf is not simply proportional to the rate of change of the magnetic field, \vec{B} ; it depends also on the loop's area and angle. That is, the emf is proportional to the rate of change of the **magnetic flux**, Φ_B , through the loop. Magnetic flux for a uniform magnetic field through a loop of area A is defined as

$$
\Phi_B = B_\perp A = BA \cos \theta. \qquad [B \text{ uniform}] \quad (21-1)
$$

Here B_1 is the component of the magnetic field \vec{B} perpendicular to the face of the loop, and θ is the angle between **B** and a line perpendicular to the face of the loop. These quantities are shown in Fig. $21-3$ for a square loop of side l whose area is $A = l^2$. When the face of the loop is parallel to \vec{B} , $\theta = 90^\circ$ and $\Phi_B = 0$. When **B** is perpendicular to the loop, $\theta = 0^{\circ}$, and

$$
\Phi_B = BA.
$$
 [uniform $\vec{B} \perp$ loop face]

As we saw in Chapter 20, the lines of \vec{B} (like lines of \vec{E}) can be drawn such that the number of lines per unit area is proportional to the field strength. Then the flux Φ_B can be thought of as being proportional to the *total number of lines* passing through the area enclosed by the loop. This is illustrated in Fig. 21-4, where the loop is viewed from the side (on edge). For $\theta = 90^{\circ}$, no magnetic field lines pass through the loop and $\Phi_B = 0$, whereas Φ_B is a maximum when $\theta = 0^\circ$. The unit of magnetic flux is the tesla-meter²; this is called a **weber**: $1 \text{ Wb} = 1 \text{ T} \cdot \text{m}^2$.

CONCEPTUAL EXAMPLE 21-1 Determining flux. A square loop of wire encloses area A_1 as shown in Fig. 21–5. A uniform magnetic field \vec{B} perpendicular to the loop extends over the area A_2 . What is the magnetic flux through the loop A_1 ?

RESPONSE We assume that the magnetic field is zero outside the area A_2 . The total magnetic flux through area A_1 is the flux through area A_2 , which by Eq. 21-1 for a uniform field is BA_2 , plus the flux through the remaining area (= $A_1 - A_2$), which is zero because $B = 0$. So the total flux is $\Phi_B = BA_2 + 0(A_1 - A_2) = BA_2$. It is *not* equal to BA_1 because **B** is not uniform over A_1 .

EXAMPLE 21-2 Calculate the flux. A square loop of wire 10.0 cm on a side is in a 1.25 -T magnetic field B . What are the maximum and minimum values of flux that can pass through the loop?

APPROACH The flux is given by Eq. 21–1. It is a maximum for $\theta = 0^{\circ}$, which occurs when the plane of the loop is perpendicular to \vec{B} . The minimum value occurs when $\theta = 90^{\circ}$ and the plane of the loop is aligned with **B**. **SOLUTION** From Eq. $21-1$, the maximum value is

$$
\Phi_B = BA \cos \theta = (1.25 \text{ T})(0.100 \text{ m})(0.100 \text{ m}) \cos 0^\circ = 0.0125 \text{ Wb}.
$$

The minimum value is 0 Wb when $\theta = 90^{\circ}$ and $\cos 90^{\circ} = 0$.

EXERCISE A Find the flux in Example $21-2$ when the perpendicular to the coil makes a 35 $^{\circ}$ angle with **B**.

With our definition of flux, Eq. 21–1, we can now write down the results of Faraday's investigations. If the flux through a loop of wire changes by an amount $\Delta \Phi_B$ over a very brief time interval Δt , the induced emf at this instant is

$$
\mathscr{E} = -\frac{\Delta \Phi_B}{\Delta t}.
$$
 [1 loop] (21-2a)

This fundamental result is known as Faraday's law of induction, and it is one of the basic laws of electromagnetism.
If the circuit contains N closely wrapped loops, the emfs induced in each loop add together, so

$$
\mathscr{E} = -N \, \frac{\Delta \Phi_B}{\Delta t}.
$$

$$
[N\text{ loops}] \quad (21-2b)
$$

The minus sign in Eqs. $21-2$ is there to remind us in which direction the induced emf acts. Experiments show that

a current produced by an induced emf moves in a direction so that its magnetic field opposes the original change in flux.

This is known as **Lenz's law**. Be aware that we are now discussing two distinct magnetic fields: (1) the changing magnetic field or flux that induces the current, and (2) the magnetic field produced by the induced current (all currents produce a field). The second field opposes the change in the first.

Let us now apply Lenz's law to the relative motion between a magnet and a coil, Fig. 21-2. The changing flux through the coil induces an emf in the coil, producing a current. This induced current produces its own magnetic field. In Fig. 21–2a the distance between the coil and the magnet decreases. The magnet's magnetic field (and number of field lines) through the coil increases, and therefore the flux increases. The magnetic field of the magnet points upward. To oppose the upward increase, the magnetic field inside the coil produced by the induced current needs to point *downward*. Thus, Lenz's law tells us that the current moves as shown (use the right-hand rule). In Fig. $21-2b$, the flux *decreases* (because the magnet is moved away and B decreases), so the induced current in the coil produces an upward magnetic field through the coil that is "trying" to maintain the status quo. Thus the current in Fig. 21–2b is in the opposite direction from Fig. 21–2a.

It is important to note that an emf is induced whenever there is a change in flux through the coil, and we now consider some more possibilities.

Since magnetic flux $\Phi_B = BA \cos \theta$, we see that an emf can be induced in three ways: (1) by a changing magnetic field B ; (2) by changing the area A of the loop in the field; or (3) by changing the loop's orientation θ with respect to the field. Figures $21-1$ and $21-2$ illustrated case 1. Examples of cases 2 and 3 are illustrated in Figs. 21-6 and 21-7, respectively.

FARADAY'S LAW OF INDUCTION

Lenz's law

FIGURE 21-6 A current can be induced by changing the area of the coil, even though B doesn't change. In both this case and that of Fig. $21-7$, the *flux* through the coil is reduced as we go from (a) to (b) . Here the brief induced current acts in the direction shown so as to try to maintain the original flux ($\Phi = BA$) by producing its own magnetic field into the page. That is, as the area A decreases, the current acts to increase B in the original (inward) direction.

Three ways to change the magnetic flux: change B , A , or θ

FIGURE 21-7 A current can be induced by rotating a coil in a magnetic field. The flux through the coil changes from (a) to (b) because θ (in Eq. 21-1) went from 0° (cos $\theta = 1$) to 90° (cos $\theta = 0$).

FIGURE $21-8$ Example $21-3$: An induction stove.

PROBLEM SOLVING Lenz's Law

Lenz's law is used to determine the direction of the (conventional) electric current induced in a loop due to a change in magnetic flux inside the loop. To produce an induced current you need

- (a) a closed conducting loop, and
- (b) an external magnetic flux through the loop that is changing in time.
- **1.** Determine whether the magnetic flux ($\Phi = BA \cos \theta$) inside the loop is decreasing, increasing, or unchanged.
- 2. The magnetic field due to the induced current: (a) points in the same direction as the external

RESPONSE The ac current sets up a changing magnetic field that passes through the pan bottom. This changing magnetic field induces a current in the pan bottom, and since the pan offers resistance, electric energy is transformed to thermal energy which heats the pot and its contents. A glass container offers such high resistance that little current is induced and little energy is transferred $(P = V^2/R)$.

CONCEPTUAL EXAMPLE 21-3 Induction stove. In an induction stove (Fig. 21–8), an ac current passes around a coil that is the "burner" (a burner that never gets hot). Why will it heat a metal pan but not a glass container?

> field if the flux is decreasing; (b) points in the opposite direction as the external field if the flux is increasing; or (c) is zero if the flux is not changing.

- 3. Once you know the direction of the induced magnetic field, use right-hand-rule-1 (p. 562) to find the direction of the induced current.
- 4. Always keep in mind that there are two magnetic fields: (1) an external field whose flux must be changing if it is to induce an electric current, and (2) a magnetic field produced by the induced current.

FIGURE $21-9$ Example $21-4$.

Magnetic field of induced current opposes change in external flux, not necessarily opposing the external field **CONCEPTUAL EXAMPLE 21-4** Practice with Lenz's law. In which direction is the current induced in the loop for each situation in Fig. 21–9?

RESPONSE (a) Initially, the magnetic field pointing out of the page passes through the loop. If you pull the loop out of the field, magnetic flux through the loop decreases; so the induced current will be in a direction to maintain the decreasing flux through the loop: the current will be counterclockwise to produce a magnetic field outward (toward the reader).

 (b) The external field is into the page. The coil area gets smaller, so the flux will decrease; hence the induced current will be clockwise, producing its own field into the page to make up for the flux decrease.

(c) Magnetic field lines point out from the N pole of a magnet, so as the magnet moves toward the loop, the magnet's field points into the page and is getting stronger. The current in the loop will be induced in the counterclockwise direction in order to produce a field \vec{B} *out* of the page.

 (d) The field is in the plane of the loop, so no magnetic field lines pass through the loop and the flux through the loop is zero throughout the process; hence there is no change in external magnetic flux with time, and there will be no induced emf or current in the loop.

 (e) Initially there is no flux through the loop. When you start to rotate the loop, the external field through the loop begins increasing to the left. To counteract this change in flux, the loop will have current induced in a counterclockwise direction so as to produce its own field to the right.

EXAMPLE 21-5 Pulling a coil from a magnetic field. A square coil of wire with side $l = 5.00$ cm contains 100 loops and is positioned perpendicular to a uniform 0.600-T magnetic field, as shown in Fig. 21-10. It is quickly pulled from the field at constant speed (moving perpendicular to \vec{B}) to a region where B drops abruptly to zero. At $t = 0$, the right edge of the coil is at the edge of the field. It takes 0.100s for the whole coil to reach the field-free region. The coil's total resistance is 100 Ω . Find (*a*) the rate of change in flux through the coil, and (b) the emf and current induced. (c) How much energy is dissipated in the coil? (d) What was the average force required?

APPROACH We start by finding how the magnetic flux, $\Phi_B = BA$, changes during the time interval $\Delta t = 0.100$ s. Faraday's law then gives the induced emf and Ohm's law gives the current.

SOLUTION (a) The area of the coil is $A = l^2 = (5.00 \times 10^{-2} \text{ m})^2 = 2.50 \times 10^{-3} \text{ m}^2$. The flux is initially $\Phi_B = BA = (0.600 \text{ T})(2.50 \times 10^{-3} \text{ m}^2) = 1.50 \times 10^{-3} \text{ Wb}$. After 0.100 s, the flux is zero. The rate of change in flux is constant (because the coil is square), equal to

$$
\frac{\Delta \Phi_B}{\Delta t} = \frac{0 - (1.50 \times 10^{-3} \text{ Wb})}{0.100 \text{ s}} = -1.50 \times 10^{-2} \text{ Wb/s}.
$$

(b) The emf induced (Eq. 21-2) in the 100-loop coil during this 0.100-s interval is

$$
\mathcal{E} = -N \frac{\Delta \Phi_B}{\Delta t} = -(100)(-1.50 \times 10^{-2} \,\text{Wb/s}) = 1.50 \,\text{V}.
$$

The current is found by applying Ohm's law to the 100- Ω coil:

$$
I = \frac{\mathcal{E}}{R} = \frac{1.50 \text{ V}}{100 \Omega} = 1.50 \times 10^{-2} \text{ A} = 15.0 \text{ mA}.
$$

By Lenz's law, the current must be clockwise to produce more \vec{B} into the page and thus oppose the decreasing flux into the page.

(c) The total energy dissipated in the coil is the product of the power $(= I^2 R)$ and the time:

$$
E = Pt = I2Rt = (1.50 \times 10^{-2} \text{ A})^{2}(100 \ \Omega)(0.100 \text{ s}) = 2.25 \times 10^{-3} \text{ J}.
$$

 (d) We can use the result of part (c) and apply the work-energy principle: the energy dissipated E is equal to the work W needed to pull the coil out of the field (Chapter 6). Because $W = \overline{F}d$ where $d = 5.00$ cm, then

$$
\overline{F} = \frac{W}{d} = \frac{2.25 \times 10^{-3} \text{ J}}{5.00 \times 10^{-2} \text{ m}} = 0.0450 \text{ N}.
$$

Alternate Solution (d) We can also calculate the force directly using $F = IlB$, Eq. 20–2 for constant **B**. The force the magnetic field exerts on the top and bottom sections of the square coil of Fig. 21-10 are in opposite directions and cancel each other. The magnetic force \vec{F}_{M} exerted on the left vertical section of the square coil acts to the left as shown because the current is up (clockwise). The right side of the loop is in the region where $\vec{B} = 0$. Hence the external force, to the right, needed to just overcome the magnetic force to the left (on $N = 100$ loops) is

$$
F_{\text{ext}} = NIIB = (100)(0.0150 \text{ A})(0.0500 \text{ m})(0.600 \text{ T}) = 0.0450 \text{ N},
$$

which is the same answer, confirming our use of energy conservation above.

EXERCISE B What is the direction of the induced current in the circular loop due to the current shown in each part of Fig. 21-11?

 $\overline{\mathcal{K}}$ PHYSICS APPLIED **Blood flow measurement**

FIGURE 21-14 Measurement of blood velocity from the induced emf. Example 21-7.

21-3 EMF Induced in a Moving Conductor

Another way to induce an emf is shown in Fig. 21–12a, and this situation helps illuminate the nature of the induced emf. Assume that a uniform magnetic field \vec{B} is perpendicular to the area bounded by the U-shaped conductor and the movable rod resting on it. If the rod is made to move at a speed v , it travels a distance $\Delta x = v \Delta t$ in a time Δt . Therefore, the area of the loop increases by an amount $\Delta A = l \Delta x = Iv \Delta t$ in a time Δt . By Faraday's law there is an induced emf & whose magnitude is given by

$$
\mathcal{E} = \frac{\Delta \Phi_B}{\Delta t} = \frac{B \Delta A}{\Delta t} = \frac{Blv \Delta t}{\Delta t} = Blv.
$$
 (21-3)

Equation 21–3 is valid as long as B , l, and v are mutually perpendicular. (If they are not, we use only the components of each that are mutually perpendicular.) An emf induced on a conductor moving in a magnetic field is sometimes called *motional emf*.

We can also obtain Eq. 21-3 without using Faraday's law. We saw in Chapter 20 that a charged particle moving perpendicular to a magnetic field B with speed v experiences a force $F = qvB$ (Eq. 20–4). When the rod of Fig. 21–12a moves to the right with speed v , the electrons in the rod also move with this speed. Therefore, since $\vec{v} \perp \vec{B}$, each electron feels a force $F = qvB$, which acts up the page as shown in Fig. 21–12b. If the rod was not in contact with the U-shaped conductor, electrons would collect at the upper end of the rod, leaving the lower end positive (see signs in Fig. $21-12b$). There must thus be an induced emf. If the rod does slide on the U-shaped conductor (Fig. 21–12a), the electrons will flow into the U. There will then be a clockwise (conventional) current in the loop. To calculate the emf, we determine the work W needed to move a charge q from one end of the rod to the other against this potential difference: $W =$ force \times distance $= (qvB)(l)$. The emf equals the work done per unit charge, so $\mathscr{E} = W/q = qvBl/q = Blv$, the same result as from Faraday's law above, Eq. 21-3.

EXERCISE C In what direction will the electrons flow in Fig. $21-12$ if the rod moves to the left, decreasing the area of the current loop?

EXAMPLE 21-6 Does a moving airplane develop a large emf? An airplane travels 1000 km/h in a region where the Earth's magnetic field is 5.0×10^{-5} T and is nearly vertical (Fig. 21–13). What is the potential difference induced between the wing tips that are 70 m apart?

APPROACH We consider the wings to be a 70-m-long conductor moving through the Earth's magnetic field. We use Eq. 21-3 to get the emf.

SOLUTION Since $v = 1000 \text{ km/h} = 280 \text{ m/s}$, and $\vec{v} \perp \vec{B}$, we have

$$
\mathcal{E} = Blv = (5.0 \times 10^{-5} \text{ T})(70 \text{ m})(280 \text{ m/s}) = 1.0 \text{ V}.
$$

NOTE Not much to worry about.

EXAMPLE 21-7 Electromagnetic blood-flow measurement. The rate of blood flow in our body's vessels can be measured using the apparatus shown in Fig. $21-14$, since blood contains charged ions. Suppose that the blood vessel is 2.0 mm in diameter, the magnetic field is 0.080 T, and the measured emf is 0.10 mV. What is the flow velocity of the blood?

APPROACH The magnetic field **B** points horizontally from left to right (N pole toward S pole). The induced emf acts over the width $l = 2.0$ mm of the blood vessel (Fig. 21–14), perpendicular to \vec{B} and \vec{v} , just as in Fig. 21–12. We can then use Eq. 21-3 to get v .

SOLUTION We solve for v in Eq. 21-3:

$$
v = \frac{\mathcal{E}}{Bl} = \frac{(1.0 \times 10^{-4} \text{ V})}{(0.080 \text{ T})(2.0 \times 10^{-3} \text{ m})} = 0.63 \text{ m/s}.
$$

NOTE In actual practice, an alternating current is used to produce an alternating magnetic field. The induced emf is then alternating.

CHAPTER 21 Electromagnetic Induction and Faraday's Law 590

Additional Example

EXAMPLE 21-8 Force on the rod. To make the rod of Fig. 21-12a move to the right at speed v , you need to apply an external force on the rod to the right. (a) Explain and determine the magnitude of the required force. (b) What external power is needed to move the rod? (Do not confuse this external force on the rod with the upward force on the electrons shown in Fig. $21-12b$.)

APPROACH When the rod moves to the right, electrons flow upward in the rod according to right-hand-rule-3 ($p.562$). So the conventional current is downward in the rod. We can see this also from Lenz's law: the outward magnetic flux through the loop is increasing, so the induced current must oppose the increase. Thus the current is clockwise so as to produce a magnetic field into the page (right-hand-rule-1). The magnetic force on the moving rod is $F = IIB$ for a constant B (Eq. 20-2). Right-hand-rule-2 tells us this magnetic force is to the left, and is thus a "drag force" opposing our effort to move the rod to the right.

SOLUTION (a) The magnitude of the external force, to the right, needs to balance the magnetic force $F = IlB$. The current $I = \mathcal{E}/R = Blv/R$ (see Eq. 21–3), and the resistance R is that of the whole circuit: the rod and the U-shaped conductor. The force F required to move the rod is thus

$$
F = IlB = \left(\frac{Blv}{R}\right)lB = \frac{B^2l^2}{R}v.
$$

If B , l , and R are constant, then a constant speed v is produced by a constant force. (Constant R implies that the parallel rails have negligible resistance.) (b) The external power needed to move the rod for constant R is

$$
P_{\rm ext} = Fv = \frac{B^2 l^2 v^2}{R}.
$$

The power dissipated in the resistance is $P = I^2 R$. With $I = \mathcal{E}/R = Blv/R$,

$$
P_{\rm R}=I^2R=\frac{B^2l^2v^2}{R},
$$

so the power input equals that dissipated in the resistance at any moment.

21-4 Changing Magnetic Flux Produces an **Electric Field**

We have seen that a changing magnetic flux induces an emf; there also is an induced current. This implies there is an electric field in a wire, causing the electrons to start moving. Indeed, this and other results suggest the important conclusion that

a changing magnetic field induces an electric field.

This applies not only to wires and other conductors, but is a general result that applies to any region in space: an electric field will be induced at any point in space where there is a changing magnetic field.

We can get a simple formula for E in terms of B for the case of electrons in a moving conductor, as in Fig. $21-12$. The electrons feel a force (upwards in Fig. $21-12b$); and if we put ourselves in the reference frame of the conductor, this force accelerating the electrons implies that there is an electric field in the conductor. Electric field is defined as the force per unit charge, $E = F/q$, where here $F = qvB$ (Eq. 20–4). Thus the effective field E in the rod must be

$$
E = \frac{F}{q} = \frac{qvB}{q} = vB.
$$

SECTION 21-4 Changing Magnetic Flux Produces an Electric Field 591

FIGURE 21-15 An ac generator.

FIGURE $21-16$ (a) A dc generator with one set of commutators, and (b) a dc generator with many sets of commutators and windings.

FIGURE 21-17 The emf is induced in the segments ab and cd, whose velocity components perpendicular to the field \vec{B} are $v \sin \theta$.

21-5 Electric Generators

We discussed alternating currents (ac) in Section 18–7. Now we examine how ac is generated, by an electric generator or dynamo, one of the most important practical results of Faraday's great discovery. A generator transforms mechanical energy into electric energy, just the opposite of what a motor does. A simplified diagram of an **ac generator** is shown in Fig. $21-15$. A generator consists of many loops of wire (only one is shown) wound on an *armature* that can rotate in a magnetic field. The axle is turned by some mechanical means (falling water, steam turbine, car motor belt), and an emf is induced in the rotating coil. An electric current is thus the *output* of a generator. Suppose in Fig. 21-15 that the armature is rotating clockwise; then right-hand-rule-3 applied to charged particles in the wire (or Lenz's law) tells us that the (conventional) current in the wire labeled b on the armature is outward; therefore the current is outward at brush b. (Each brush is fixed and presses against a continuous slip ring that rotates with the armature.) After one-half revolution, wire b will be where wire a is now in the drawing, and the current then at brush b will be inward. Thus the current produced is alternating.

The frequency f is 60 Hz for general use in the United States and Canada, whereas 50 Hz is used in many countries. Most of the power generated in the United States is done at steam plants, where the burning of fossil fuels (coal, oil, natural gas) boils water to produce high-pressure steam that turns a turbine connected to the generator axle (Fig. $15-21$). At nuclear power plants, the nuclear energy released is used to produce steam to turn turbines. Indeed, a heat engine (Chapter 15) connected to a generator is the principal means of generating electric power. The frequency of 60 Hz or 50 Hz is maintained very precisely by power companies.

A dc generator is much like an ac generator, except the slip rings are replaced by split-ring commutators, Fig. 21-16a, just as in a dc motor. The output of such a generator is as shown and can be smoothed out by placing a capacitor in parallel with the output (Section $19-6$). More common is the use of many armature windings, as in Fig. 21–16b, which produces a smoother output.

Automobiles used to use dc generators. Today they mainly use alternators, which avoid the problems of wear and electrical arcing (sparks) across the splitring commutators of de generators. Alternators differ from generators in that an electromagnet, called the *rotor*, is fed by current from the battery and is made to rotate by a belt from the engine. The magnetic field of the turning rotor passes through a surrounding set of stationary coils called the *stator*, inducing an alternating current in the stator coils, which is the output. This ac output is changed to dc for charging the battery by the use of semiconductor diodes, which allow current flow in one direction only.

Deriving the Generator Equation

Figure $21-17$ shows the wire loop on a generator armature. The loop is being made to rotate clockwise in a uniform magnetic field \vec{B} . The velocity of the two lengths ab and cd at this instant are shown. Although the sections of wire bc and da are moving, the force on electrons in these sections is toward the side of the wire, not along the wire's length. The emf generated is thus due only to the force on charges in the sections ab and cd. From right-hand-rule-3, we see that the direction of the induced current in ab is from a toward b. And in the lower section, it is from c to d; so the flow is continuous in the loop. The magnitude of the emf generated in ab is given by Eq. $21-3$, except that we must take the component of the velocity perpendicular to B :

$$
\mathscr{E}=Blv
$$

where l is the length of ab. From Fig. 21–17 we can see that $v_1 = v \sin \theta$, where θ is the angle the face of the loop makes with the vertical. The emf induced in cd has the same magnitude and is in the same direction. Therefore their emfs add,

592 CHAPTER 21 Electromagnetic Induction and Faraday's Law

and the total emf is

 $\mathscr{E} = 2NBlv \sin \theta$.

where we have multiplied by N , the number of loops in the coil.

If the coil is rotating with constant angular velocity ω , then the angle $\theta = \omega t$. We also have from the angular equations (Eq. 8–4) that $v = \omega r = \omega(h/2)$, where h is the length of bc or ad. Thus $\mathscr{E} = 2NB\omega l(h/2) \sin \omega t$, or

$$
\mathscr{E}=N B \omega A \sin \omega t,
$$

where $A = lh$ is the area of the loop. This equation holds for any shape coil, not just for a rectangle as derived. Thus, the output emf of the generator is sinusoidally alternating (see Fig. 21–18 and Section 18–7). Since ω is expressed in radians per second, we can write $\omega = 2\pi f$, where f is the frequency.

-6 Back EMF and Counter Torque; Eddy Currents

* Back EMF

A motor turns and produces mechanical energy when a current is made to flow in it. From our description in Section 20–10 of a simple dc motor, you might expect that the armature would accelerate indefinitely due to the torque on it. However, as the armature of the motor turns, the magnetic flux through the coil changes and an emf is generated. This induced emf acts to oppose the motion (Lenz's law) and is called the back emf or counter emf. The greater the speed of the motor, the greater the back emf. A motor normally turns and does work on something, but if there were no load, the motor's speed would increase until the back emf equaled the input voltage. When there is a mechanical load, the speed of the motor may be limited also by the load. The back emf will then be less than the external applied voltage. The greater the mechanical load, the slower the motor rotates and the lower is the back emf ($\& \propto \omega$, Eq. 21-5).

EXAMPLE 21-9 Back emf in a motor. The armature windings of a dc motor have a resistance of 5.0 Ω . The motor is connected to a 120-V line, and when the motor reaches full speed against its normal load, the back emf is 108 V. Calculate (a) the current into the motor when it is just starting up, and (b) the current when the motor reaches full speed.

APPROACH As the motor is just starting up, it is turning very slowly, so there is no induced back emf. The only voltage is the 120-V line. The current is given by Ohm's law with $R = 5.0 \Omega$. At full speed, we must include as emfs both the 120-V applied emf and the opposing back emf.

SOLUTION (a) At start up, the current is controlled by the 120 V applied to the coil's 5.0- Ω resistance. By Ohm's law,

$$
I = \frac{V}{R} = \frac{120 \text{ V}}{5.0 \Omega} = 24 \text{ A}.
$$

(b) When the motor is at full speed, the back emf must be included in the equivalent circuit shown in Fig. 21-19. In this case, Ohm's law (or Kirchhoff's rule) gives

$$
120\,\mathrm{V} - 108\,\mathrm{V} = I(5.0\,\Omega).
$$

Therefore

$$
I = \frac{12 \text{ V}}{5.0 \text{ }\Omega} = 2.4 \text{ A}.
$$

NOTE This result shows that the current can be very high when a motor first starts up. This is why the lights in your house may dim when the motor of the refrigerator (or other large motor) starts up. The large initial current causes the voltage at the outlets to drop, since the house wiring has resistance and there is some voltage drop across it when large currents are drawn.

FIGURE 21-18 An ac generator produces an alternating current. The output emf $\mathscr{E} = \mathscr{E}_0 \sin \omega t$, where $\mathscr{E}_0 = N A \omega B$ (Eq. 21-5).

 $(21-5)$

CONCEPTUAL EXAMPLE 21-10 Motor overload. When using an appliance such as a blender, electric drill, or sewing machine, if the appliance is overloaded or jammed so that the motor slows appreciably or stops while the power is still connected, the device can burn out and be ruined. Explain why this happens.

RESPONSE The motors are designed to run at a certain speed for a given applied voltage, and the designer must take the expected back emf into account. If the rotation speed is reduced, the back emf will not be as high as expected ($\& \propto \omega$, Eq. 21–5), and the current will increase, and may become large enough that the windings of the motor heat up to the point of ruining the motor.

* Counter Torque

In a generator, the situation is the reverse of that for a motor. As we saw, the mechanical turning of the armature induces an emf in the loops, which is the output. If the generator is not connected to an external circuit, the emf exists at the terminals but there is no current. In this case, it takes little effort to turn the armature. But if the generator is connected to a device that draws current, then a current flows in the coils of the armature. Because this current-carrying coil is in an external magnetic field, there will be a torque exerted on it (as in a motor), and this torque opposes the motion (use right-hand-rule-2 for the force on a wire, in Fig. $21-15$ or $21-17$). This is called a **counter torque**. The greater the electrical load—that is, the more current that is drawn—the greater will be the counter torque. Hence the external applied torque will have to be greater to keep the generator turning. This makes sense from the conservation of energy principle. More mechanical-energy input is needed to produce more electrical-energy output.

* Eddy Currents

Induced currents are not always confined to well-defined paths such as in wires. Consider, for example, the rotating metal wheel in Fig. 21-20a. An external magnetic field is applied to a limited area of the wheel as shown and points into the paper. The section of wheel in the magnetic field has an emf induced in it because the conductor is moving, carrying electrons with it. The flow of (conventional) current in the wheel is upward in the region of the magnetic field (Fig. 21–20b), and the current follows a downward return path outside that region. Why? According to Lenz's law, the induced currents oppose the change that causes them. Consider the part of the wheel labeled c in Fig. 21-20b, where the magnetic field is zero but is just about to enter a region where **B** points into the page. To oppose this inward increase in magnetic field, the induced current is counterclockwise to produce a field pointing out of the page (right-hand-rule-1). Similarly, region d is about to move to e, where \vec{B} is zero; hence the current is clockwise to produce an inward field opposed to this decreasing flux inward. These currents are referred to as eddy currents. They can be present in any conductor that is moving across a magnetic field or through which the magnetic flux is changing.

In Fig. 21–20b, the magnetic field exerts a force \vec{F} on the induced currents it has created, and that force opposes the rotational motion. Eddy currents can be used in this way as a smooth braking device on, say, a rapid-transit car. In order to stop the car, an electromagnet can be turned on that applies its field either to the wheels or to the moving steel rail below. Eddy currents can also be used to dampen (reduce) the oscillation of a vibrating system. Eddy currents, however, can be a problem. For example, eddy currents induced in the armature of a motor or generator produce heat ($P = I\mathscr{E}$) and waste energy. To reduce the eddy currents, the armatures are laminated; that is, they are made of very thin sheets of iron that are well insulated from one another. The total path length of the eddy currents is confined to each slab, which increases the total resistance; hence the current is less and there is less wasted energy.

FIGURE 21-20 Production of eddy currents in a rotating wheel.

Counter toraue

Walk-through metal detectors at airports (Fig. 21-21) detect metal objects using electromagnetic induction and eddy currents. Several coils are situated in the walls of the walk-through at different heights. In a technique called "pulse induction," the coils are given repeated brief pulses of current (on the order of microseconds), hundreds or thousands of times a second. Each pulse in a coil produces a magnetic field for a very brief period of time. When a passenger passes through the walk-through, any metal object being carried will have eddy currents induced in it. The eddy currents persist briefly after each input pulse, and the small magnetic field produced by the persisting eddy current (before the next external pulse) can be detected, setting off an alert or alarm. Stores and libraries use similar systems to prevent theft.

Transformers and Transmission of Power

A transformer is a device for increasing or decreasing an ac voltage. Transformers are found everywhere: in TV sets to give the high voltage needed for the picture tube, in converters for plugging in a portable stereo, on utility poles (Fig. $21-22$) to reduce the high voltage from the electric company to a usable voltage in houses $(120 V or 240 V)$, and in many other applications. A transformer consists of two coils of wire known as the primary and secondary coils. The two coils can be interwoven (with insulated wire); or they can be linked by an iron core which is laminated to minimize eddy-current losses (Section $21-6$), as shown in Fig. $21-23$. Transformers are designed so that (nearly) all the magnetic flux produced by the current in the primary coil also passes through the secondary coil, and we assume this is true in what follows. We also assume that energy losses (in resistance and hysteresis) can be ignored—a good approximation for real transformers, which are often better than 99% efficient.

When an ac voltage is applied to the primary coil, the changing magnetic field it produces will induce an ac voltage of the same frequency in the secondary coil. However, the voltage will be different according to the number of loops in each coil. From Faraday's law, the voltage or emf induced in the secondary coil is

$$
V_{\rm S} = N_{\rm S} \frac{\Delta \Phi_B}{\Delta t}
$$

where N_s is the number of turns in the secondary coil, and $\Delta \Phi_B / \Delta t$ is the rate at which the magnetic flux changes.

The input primary voltage, V_p , is related to the rate at which the flux changes through it,

$$
V_{\rm P} = N_{\rm P} \frac{\Delta \Phi_B}{\Delta t},
$$

where N_p is the number of turns in the primary coil. We divide these two equations, assuming little or no flux is lost, to find

$$
\frac{V_{\rm S}}{V_{\rm P}} = \frac{N_{\rm S}}{N_{\rm P}}.
$$

This *transformer equation* tells how the secondary (output) voltage is related to the primary (input) voltage; V_s and V_p in Eq. 21–6 can be the rms values (Section 18-7) for both, or peak values for both. DC voltages don't work in a transformer because there would be no changing magnetic flux.

PHYSICS APPLIED Airport metal detector

FIGURE 21-21 Airport metal detector.

FIGURE 21-22 Repairing a stepdown transformer on a utility pole.

FIGURE 21-23 Step-up transformer ($N_{\rm P} = 4$, $N_{\rm S} = 12$).

 $(21-6)$ Transformer equation

If the secondary coil contains more loops than the primary coil $(N_s > N_p)$, we have a **step-up transformer**. The secondary voltage is greater than the primary voltage. For example, if the secondary coil has twice as many turns as the primary coil, then the secondary voltage will be twice that of the primary voltage. If N_s is less than N_p , we have a **step-down transformer**.

Although ac voltage can be increased (or decreased) with a transformer, we don't get something for nothing. Energy conservation tells us that the power output can be no greater than the power input. A well-designed transformer can be greater than 99% efficient, so little energy is lost to heat. The power output thus essentially equals the power input. Since power $P = IV$ (Eq. 18–5), we have

> $I_{\rm P}V_{\rm P} = I_{\rm S}V_{\rm S}$, $\frac{I_{\rm S}}{I_{\rm p}} = \frac{N_{\rm p}}{N_{\rm s}}.$ $(21-7)$

EXAMPLE 21-11 Portable radio transformer. A transformer for home use of a portable radio reduces 120-V ac to 9.0-V ac. (Such a device also contains diodes to change the 9.0-V ac to dc, to be like its 9.0-V battery.) The secondary coil contains 30 turns and the radio draws 400 mA. Calculate (a) the number of turns in the primary coil, (b) the current in the primary, and (c) the power transformed.

APPROACH We assume the transformer is ideal, with no flux loss, so we can use Eq. 21–6 and then Eq. 21–7.

SOLUTION (a) This is a step-down transformer, and from Eq. 21–6 we have

$$
N_{\rm P} = N_{\rm S} \frac{V_{\rm P}}{V_{\rm S}} = \frac{(30)(120 \text{ V})}{(9.0 \text{ V})} = 400 \text{ turns.}
$$

(b) From Eq. $21-7$,

$$
I_{\rm P} = I_{\rm S} \frac{N_{\rm S}}{N_{\rm P}} = (0.40 \,\mathrm{A}) \left(\frac{30}{400} \right) = 0.030 \,\mathrm{A}.
$$

 (c) The power transformed is

 $P = I_{S}V_{S} = (0.40 \text{ A})(9.0 \text{ V}) = 3.6 \text{ W}.$

NOTE The power in the primary coil, $P = (0.030 \text{ A})(120 \text{ V}) = 3.6 \text{ W}$, is the same as the power in the secondary coil. There is 100% efficiency in power transfer for our ideal transformer.

EXERCISE D How many turns would you want in the secondary coil of the transformer in Example 21–11 ($N_p = 400$ turns) if it were to reduce the voltage from 120-V ac to 3.0-V ac?

A transformer operates only on ac. A dc current in the primary coil does not produce a changing flux and therefore induces no emf in the secondary. However, if a dc voltage is applied to the primary through a switch, at the instant the switch is opened or closed there will be an induced current in the secondary. For example, if the dc is turned on and off as shown in Fig. $21-24a$, the voltage induced in the secondary is as shown in Fig. $21-24b$. Notice that the secondary voltage drops to zero when the dc voltage is steady. This is basically how, in the ignition system of an automobile, the high voltage is created to produce the spark across the gap of a spark plug that ignites the gas-air mixture. The transformer is referred to simply as an "ignition coil," and transforms the 12 V of the battery (when switched off in the primary) into a spike of as much as $30 \, \text{kV}$ in the secondary.

FIGURE 21-24 A dc voltage turned on and off as shown in (a) produces voltage pulses in the secondary (b). Voltage scales in (a) and (b) are not the same.

Transformer equation II

FIGURE 21-25 The transmission of electric power from power plants to homes makes use of transformers at various stages.

Transformers play an important role in the transmission of electricity. Power plants are often situated some distance from metropolitan areas, so electricity must then be transmitted over long distances (Fig. 21–25). There is always some power loss in the transmission lines, and this loss can be minimized if the power is transmitted at high voltage, using transformers, as the following Example shows.

EXAMPLE 21-12 Transmission lines. An average of 120 kW of electric power is sent to a small town from a power plant 10 km away. The transmission lines have a total resistance of 0.40Ω . Calculate the power loss if the power is transmitted at (a) 240 V and (b) $24,000$ V.

APPROACH We cannot use $P = V^2/R$ because if R is the resistance of the transmission lines, we don't know the voltage drop along them; the given voltages are applied across the lines plus the load (the town). But we can determine the current I in the lines (= P/V), and then find the power loss from $P_L = I^2 R$, for both cases (a) and (b) .

SOLUTION (a) If 120 kW is sent at 240 V, the total current will be

$$
I = \frac{P}{V} = \frac{1.2 \times 10^5 \text{ W}}{2.4 \times 10^2 \text{ V}} = 500 \text{ A}.
$$

The power loss in the lines, P_L , is then

$$
P_{\rm L} = I^2 R = (500 \,\mathrm{A})^2 (0.40 \,\Omega) = 100 \,\mathrm{kW}.
$$

Thus, over 80% of all the power would be wasted as heat in the power lines! (b) If 120 kW is sent at $24,000 \text{ V}$, the total current will be

$$
I = \frac{P}{V} = \frac{1.2 \times 10^5 \text{ W}}{2.4 \times 10^4 \text{ V}} = 5.0 \text{ A}.
$$

The power loss in the lines is then

$$
P_{\rm L} = I^2 R = (5.0 \,\mathrm{A})^2 (0.40 \,\Omega) = 10 \,\mathrm{W},
$$

which is less than $\frac{1}{100}$ of 1%.

NOTE We see that the higher voltage results in less current, and thus less power is wasted as heat in the transmission lines. It is for this reason that power is usually transmitted at very high voltages, as high as 700 kV.

The great advantage of ac, and a major reason it is in nearly universal use, is that the voltage can easily be stepped up or down by a transformer. The output voltage of an electric generating plant is stepped up prior to transmission. Upon arrival in a city, it is stepped down in stages at electric substations prior to distribution. The voltage in lines along city streets is typically 2400 V and is stepped down to 240 V or 120 V for home use by transformers (Figs. 21-22 and 21-25).

PHYSICS APPLIED Transformers help power transmission

FIGURE 21-26 Diagram of a microphone that works by induction.

 \overline{X} PHYSICS APPLIED Computers and digital information

21-8 Applications of Induction: Sound Systems, Computer Memory, Seismograph, GFCI

Microphone

There are various types of *microphones*, and many operate on the principle of induction. In one form, a microphone is just the inverse of a loudspeaker (Section 20-10). A small coil connected to a membrane is suspended close to a small permanent magnet, as shown in Fig. 21-26. The coil moves in the magnetic field when sound waves strike the membrane and this motion induces an emf. The frequency of the induced emf will be just that of the impinging sound waves, and this emf is the "signal" that can be amplified and sent to loudspeakers, or sent to a recorder.

Read/Write on Tape and Disks

Recording and playback on tape or disks is done by magnetic heads. Recording tapes for use in audio and video tape recorders contain a thin layer of magnetic oxide on a thin plastic tape. During recording, the audio and/or video signal voltage is sent to the recording head, which acts as a tiny electromagnet (Fig. $21-27$) that magnetizes the tiny section of tape passing over the narrow gap in the head at each instant. In playback, the changing magnetism of the moving tape at the gap causes corresponding changes in the magnetic field within the soft-iron head, which in turn induces an emf in the coil (Faraday's law). This induced emf is the output signal that can be amplified and sent to a loudspeaker (audio) or to the picture tube (video). In audio and video recorders, the signals may be *analog*—they vary continuously in amplitude over time. The variation in degree of magnetization of the tape at any point reflects the variation in amplitude and frequency of the audio or video signal.

Digital information, such as used on computer disks (hard drive or zip drive) or on magnetic computer tape and some types of digital tape recorders, is read and written using heads that are basically the same as just described (Fig. $21-27$). The essential difference is in the signals, which are not analog, but are digital, and in particular binary, meaning that only two values are possible for each of the extremely high number of predetermined spaces on the tape or disk. The two possible values are usually referred to as 1 and 0. The signal voltage does not vary continuously but rather takes on only two values, $+5V$ and 0V, for example, corresponding to the 1 or 0. Thus, information is carried as a series of "bits," each of which can have only one of two values, 1 or 0.

FIGURE $21-27$ (a) Read/Write (playback/recording) head for tape or disk. In writing or recording, the electric input signal to the head, which acts as an electromagnet, magnetizes the passing tape or disk. In reading or playback, the changing magnetic field of the passing tape or disk induces a changing magnetic field in the head, which in turn induces in the coil an emf that is the output signal. (b) Photo of a hard drive showing several platters and read/write heads that can quickly move from the edge of the disk to the center.

Credit Card Swipe

When you swipe your credit card at a store or gas station, the magnetic stripe on the back of the card passes over a read head just as in a tape recorder or computer. The magnetic stripe contains personal information about your account and connects by telephone line for approval if your account is in order.

Seismograph

In geophysics, a **seismograph** measures the intensity of earthquake waves using a magnet and a coil of wire. Either the magnet or the coil is fixed to the case. and the other is inertial (suspended by a spring; Fig. $21-28$). The relative motion of magnet and coil when the Earth shakes induces an emf output.

Ground Fault Circuit Interrupter (GFCI)

Fuses and circuit breakers (Sections 18–6 and 20–7) protect buildings from fire, and apparatus from damage, due to undesired high currents. But they do not turn off the current until it is very much greater than that which causes permanent damage to humans or death ($\approx 100 \text{ mA}$). If fast enough, they may protect in case of a short. A ground fault circuit interrupter (GFCI) is meant to protect humans; GFCIs can react to currents as small as 5 mA.

FIGURE 21-28 One type of seismograph, in which the coil is fixed to the case and moves with the Earth.

FIGURE 21-29 A ground fault circuit interrupter (GFCI).

Electromagnetic induction is the physical basis of a GFCI. As shown in Fig. 21-29, the two conductors of a power line leading to an electrical device (red) pass through a small iron ring. Around the ring are many loops of thin wire that serve as a sensing coil. Under normal conditions (no ground fault), the current moving in the hot wire is exactly balanced by the returning current in the neutral wire. If something goes wrong and the hot wire touches the ungrounded metal case of the device or appliance, some of the entering current can pass through a person who touches the case and then to ground (a ground fault). Then the return current in the neutral wire will be less than the entering current in the hot wire, so there is a *net current* passing through the GFCI's iron ring. Because the current is ac, it is changing and produces a changing magnetic field in the iron, thus inducing an emf in the sensing coil wrapped around the iron. For example, if a device draws 8.0 A, and there is a ground fault through a person of $100 \text{ mA} (= 0.1 \text{ A})$, then 7.9 A will appear in the neutral wire. The emf induced in the sensing coil by this 100-mA difference is amplified by a simple transistor circuit and sent to its own solenoid circuit breaker that opens the circuit at the switch S.

If the case of the faulty device is grounded, the current difference is even higher when there is a fault, and the GFCI trips immediately.

GFCIs can sense currents as low as 5 mA and react in 1 msec, saving lives. They can be small enough to fit as a wall outlet (Fig. $21-30$), or as a plug-in unit into which you plug a hair dryer or toaster. It is especially important to have GFCIs installed in kitchens, bathrooms, outdoors, and near swimming pools, where people are most in danger of touching ground. GFCIs always have a "test" button (to be sure it works) and a "reset" button (after it goes off).

FIGURE 21-30 A GFCI wall outlet. GFCIs can be recognized because they have "test" and "reset" buttons.

* Mutual Inductance

If two coils of wire are near one another, as in Fig. 21-31, a changing current in one will induce an emf in the other. We apply Faraday's law to coil 2: the emf \mathscr{E}_2 induced in coil 2 is proportional to the rate of change of flux passing through it. A changing flux in coil 2 is produced by a changing current in coil 1. So \mathscr{E}_2 is proportional to the rate of change of the current in coil 1:

Mutual inductance

FIGURE 21-31 A changing current in one coil will induce a current in the second coil.

PHYSICS APPLIED Pacemaker

 $\label{eq:4} \mathcal{E}_2 \,=\, -M\,\frac{\Delta I_{\rm I}}{\Delta t},$ $(21-8a)$

where we assume the time interval Δt is very small, and the constant of proportionality, M , is called the **mutual inductance**. (The minus sign is because of Lenz's law.) Mutual inductance has units of $V \cdot s/A = \Omega \cdot s$, which is called the **henry** (H), after Joseph Henry: $1 H = 1 \Omega \cdot s$.

The mutual inductance M is a "constant" in that it does not depend on I_1 ; M depends on "geometric" factors such as the size, shape, number of turns, and relative positions of the two coils, and also on whether iron (or other ferromagnetic material) is present. For example, the farther apart the two coils are in Fig. 21-31, the fewer lines of flux can pass through coil 2, so M will be less. If we consider the inverse situation—a changing current in coil 2 inducing an emf in coil 1—the proportionality constant, M , turns out to have the same value,

$$
\mathcal{E}_1 = -M \frac{\Delta I_2}{\Delta t}.
$$
 (21–8b)

A transformer is an example of mutual inductance in which the coupling is maximized so that nearly all flux lines pass through both coils. Mutual inductance has other uses as well, including some types of *pacemakers* used to maintain blood flow in heart patients (Section 19-6). Power in an external coil is transmitted via mutual inductance to a second coil in the pacemaker at the heart. This type has the advantage over battery-powered pacemakers in that surgery is not needed to replace a battery when it wears out.

* Self-Inductance

The concept of inductance applies also to an isolated single coil. When a changing current passes through a coil or solenoid, a changing magnetic flux is produced inside the coil, and this in turn induces an emf. This induced emf opposes the change in flux (Lenz's law); it is much like the back emf generated in a motor. (For example, if the current through the coil is increasing, the increasing magnetic flux induces an emf that opposes the original current and tends to retard its increase.) The induced emf $\&$ is proportional to the rate of change in current (and is in the direction opposed to the change):

Self-inductance (induced emf for an inductor)

$$
\mathcal{E} = -L \frac{\Delta I}{\Delta t}.
$$
 (21-9)

The constant of proportionality L is called the **self-inductance**, or simply the **inductance** of the coil. It, too, is measured in henrys. The magnitude of L depends on the size and shape of the coil and on the presence of an iron core.

An ac circuit (Section 18–7) always contains some inductance, but often it is quite small unless the circuit contains a coil of many loops or turns. A coil that has significant self-inductance L is called an **inductor**. It is shown on circuit diagrams by the symbol

Inductors

$$
-\text{error.} \qquad \qquad [\text{inductor symbol}]
$$

CONCEPTUAL EXAMPLE 21-13 Direction of emf in inductor. Current passes through the coil in Fig. $21-32$ from left to right as shown. (a) If the current is increasing with time, in which direction is the induced emf? (b) If the current is decreasing in time, what then is the direction of the induced emf?

RESPONSE (a) From Lenz's law we know that the induced emf must oppose the change in magnetic flux. If the current is increasing, so is the magnetic flux. The induced emf acts to oppose the increasing flux, which means it acts like a source of emf that opposes the outside source of emf driving the current. So the induced emf in the coil acts to oppose I in Fig. 21–32a. In other words, the inductor might be thought of as a battery with a positive terminal at point A (tending to block the current entering at A), and negative at point B.

 (b) If the current is decreasing, then by Lenz's law the induced emf acts to bolster the flux—like a source of emf reinforcing the external emf. The induced emf acts to increase I in Fig. 21-32b, so in this situation you can think of the induced emf as a battery with its negative terminal at point A to attract more $(+)$ current to move to the right.

EXAMPLE 21-14 Solenoid inductance. (a) Determine a formula for the self-inductance L of a tightly wrapped solenoid (a long coil) of length l and cross-sectional area A, that contains N turns (or loops) of wire. (b) Calculate the value of L if $N = 100$, $l = 5.0$ cm, $A = 0.30$ cm² and the solenoid is air filled.

APPROACH The induced emf in a coil can be determined either from Faraday's law $(\mathscr{E} = -N \Delta \Phi_B/\Delta t)$ or the self-inductance $(\mathscr{E} = -L \Delta I/\Delta t)$. If we equate these two expressions, we can solve for the inductance L since we know how to calculate the flux Φ_B for a solenoid using Eq. 20–8.

SOLUTION (a) We equate Faraday's law (Eq. 21-2b) and Eq. 21-9 for the inductance:

$$
\mathcal{E} = -N \frac{\Delta \Phi_B}{\Delta t} = -L \frac{\Delta I}{\Delta t},
$$

and solve for L:

$$
L = N \frac{\Delta \Phi_B}{\Delta I}.
$$

We know $\Phi_B = BA$ (Eq. 21–1), and Eq. 20–8 gives us the magnetic field B for a solenoid, $B = \mu_0 NI/l$, so the magnetic flux inside the solenoid is

$$
\Phi_B = \frac{\mu_0 NIA}{l}.
$$

Any change in current, ΔI , causes a change in flux

$$
\Delta \Phi_B = \frac{\mu_0 N \Delta I A}{l}.
$$

We put this into our equation above for L :

$$
L = N \frac{\Delta \Phi_B}{\Delta I} = \frac{\mu_0 N^2 A}{l}.
$$

(b) Using $\mu_0 = 4\pi \times 10^{-7} \text{T} \cdot \text{m/A}$, and putting in values given,

$$
L = \frac{(4\pi \times 10^{-7} \,\mathrm{T \cdot m/A})(100)^2(3.0 \times 10^{-5} \,\mathrm{m^2})}{(5.0 \times 10^{-2} \,\mathrm{m})} = 7.5 \,\mu\mathrm{H}.
$$

FIGURE 21-32 Example $21-13$. The $+$ and $-$ signs refer to the induced emf due to the changing current, as if points A and B were the terminals of a battery (and the coiled loops were the insides of the battery).

Calculating self-inductance of a coil

21-10 Energy Stored in a Magnetic Field

In Section 17–9 we saw that the energy stored in a capacitor is equal to $\frac{1}{2}CV^2$. By using a similar argument, it can be shown that the energy U stored in an inductance L , carrying a current I , is

$$
U = \text{energy} = \frac{1}{2}LI^2.
$$

Just as the energy stored in a capacitor can be considered to reside in the electric field between its plates, so the energy in an inductor can be considered to be stored in its magnetic field.

To write the energy in terms of the magnetic field, we use the result of Example 21–14 that the inductance of a solenoid is $L = \mu_0 N^2 A/l$. Now the magnetic field B in a solenoid is related to the current I (see Eq. 20–8) by $B = \mu_0 NI/l$. Thus, $I = Bl/\mu_0 N$, and

$$
U = \text{energy} = \frac{1}{2}LI^2 = \frac{1}{2} \left(\frac{\mu_0 N^2 A}{l} \right) \left(\frac{B l}{\mu_0 N} \right)^2 = \frac{1}{2} \frac{B^2}{\mu_0} A l.
$$

We can think of this energy as residing in the volume enclosed by the windings, which is Al . Then the energy per unit volume, or energy density, is

Energy density in magnetic field

$$
u = \text{energy density} = \frac{1}{2} \frac{B^2}{\mu_0}.
$$
 (21-10)

This formula, which was derived for the special case of a solenoid, can be shown to be valid for any region of space where a magnetic field exists. If a ferromagnetic material is present, μ_0 is replaced by μ . This equation is analogous to that for an electric field, $\frac{1}{2} \epsilon_0 E^2$, Section 17–9.

LR Circuit

Any inductor will have some resistance. We represent this situation by drawing the inductance L and the resistance R separately, as in Fig. 21–33. The resistance R could also include a separate resistor connected in series. Now we ask, what happens when a dc source is connected in series to such an LR circuit? At the instant the switch connecting the battery is closed, the current starts to flow. It is opposed by the induced emf in the inductor because of the changing current. However, as soon as current starts to flow, there is a voltage drop across the resistance $(V = IR)$. Hence, the voltage drop across the inductance is reduced, and there is then less impedance to the current flow from the inductance. The current thus rises gradually, as shown in Fig. 21-34a, and approaches the steady value $I_{\text{max}} = V/R$ when all the voltage drop is across the resistance. The shape of the curve for I as a function of time is

$$
I = \left(\frac{V}{R}\right)(1 - e^{-t/\tau}), \qquad [LR \text{ circuit with emf}]
$$

where *e* is the number $e = 2.718 \cdots$ (see Section 19–6) and $\tau = L/R$ is the **time constant** of the circuit. When $t = \tau$, then $(1 - e^{-1}) = 0.63$, so τ is the time required for the current to reach $0.63I_{\text{max}}$.

If the battery is suddenly removed from the circuit (dashed line in Fig. $21-33$), the current decreases as shown in Fig. $21-34b$. This is an exponential decay curve given by

$$
I = I_{\text{max}} e^{-t/\tau}.
$$
 [LR circuit without emf]

The time constant τ is the time for the current to decrease to 37% of the original value, and again equals L/R .

These graphs show that there is always some "reaction time" when an electromagnet, for example, is turned on or off. We also see that an LR circuit has properties similar to an RC circuit (Section 19-6). Unlike the capacitor case, however, the time constant here is *inversely* proportional to R.

602 CHAPTER 21 Electromagnetic Induction and Faraday's Law

FIGURE 21-33 LR circuit.

FIGURE $21-34$ (a) Growth of current in an LR circuit when connected to a battery; (b) decay of current when the LR circuit is shorted out (battery is out of the circuit).

EXAMPLE 21-15 Solenoid time constant. A solenoid has an inductance of 87.5 mH and a resistance of 0.250 Ω . Find (a) the time constant for this circuit, and (b) how long it would take for the current to go from zero to 63% of its final (maximum) value when connected to a battery of voltage V.

APPROACH The time constant is $\tau = L/R$. Then we use the equation for I, setting $I = 0.63I_{\text{max}}$ and solving it for t.

SOLUTION (a) By definition, $\tau = L/R = (87.5 \times 10^{-3} \text{ H})/(0.250 \Omega) = 0.350 \text{ s}.$ (b) We saw above that $I = (V/R)(1 - e^{-t/\tau})$. We wish to find t such that $I = (0.63)(V/R)$ where $V/R = I_{\text{max}}$. This occurs when $t = \tau = L/R$, so $t = 0.350$ s.

21-12 AC Circuits and Reactance

We have previously discussed circuits that contain combinations of resistor, capacitor, and inductor, but only when they are connected to a dc source of emf or to no source (as in the discharge of a capacitor in an RC circuit). Now we discuss these circuit elements when they are connected to a source of alternating voltage that produces an alternating current (ac).

First we examine, one at a time, how a resistor, a capacitor, and an inductor behave when connected to a source of alternating voltage, represented by the symbol

[alternating voltage]

which produces a sinusoidal voltage of frequency f . We assume in each case that the emf gives rise to a current

$$
I = I_0 \cos 2\pi f t,
$$

where t is time and I_0 is the peak current. Remember (Section 18-7) that $V_{\text{rms}} = V_0/\sqrt{2}$ and $I_{\text{rms}} = I_0/\sqrt{2}$ (Eq. 18–8).

* Resistor

When an ac source is connected to a resistor as in Fig. 21-35a, the current increases and decreases with the alternating emf according to Ohm's law, $I = V/R$. Figure 21-35b shows the voltage (red curve) and the current (blue curve). Because the current is zero when the voltage is zero and the current reaches a peak when the voltage does, we say that the current and voltage are in phase. Energy is transformed into heat (Section 18–7), at an average rate $\overline{P} = \overline{IV} = I_{\text{rms}}^2 R = V_{\text{rms}}^2/R$.

* Inductor

In Fig. 21–36a an inductor of inductance L (symbol \sim **mm**) is connected to the ac source. We ignore any resistance it might have (it is usually small). The voltage applied to the inductor will be equal to the "back" emf generated in the inductor by the changing current as given by Eq. 21–9. This is because the sum of the emfs around any closed circuit must be zero, as Kirchhoff's rule tells us. Thus

$$
V - L\frac{\Delta I}{\Delta t} = 0 \qquad \text{or} \qquad V = L\frac{\Delta I}{\Delta t},
$$

where V is the sinusoidally varying voltage of the source and $L \Delta I/\Delta t$ is the voltage induced in the inductor. According to this equation, I is increasing most rapidly when V has its maximum value, $\overline{V} = V_0$. And I will be decreasing most rapidly when $V = -V_0$. These two instants correspond to points d and b on the graph of voltage versus time in Fig. 21–36b. By going point by point in this manner, the curve of I versus t as compared to that for V versus t can be constructed, and they are shown by the blue and red lines, respectively, in Fig. 21–36b. Notice that the current reaches its peaks (and troughs) $\frac{1}{4}$ cycle after the voltage does. We say that

the current lags the voltage by 90° in an inductor.

Because the current and voltage in an inductor are out of phase by 90° , the product IV (= power) is as often positive as it is negative (Fig. 21–36b). So no energy is transformed in an inductor on the average; and no energy is dissipated as thermal energy.

FIGURE 21-35 (a) Resistor connected to an ac source. (b) Current (blue curve) is in phase with the voltage (red) across a resistor.

Resistor: current and voltage are in phase

FIGURE 21-36 (a) Inductor connected to an ac source. (b) Current (blue curve) lags voltage (red curve) by a quarter cycle or 90°.

Just as a resistor impedes the flow of charge, so too an inductor impedes the flow of charge in an alternating current due to the back emf produced. For a resistor R, the current and voltage are related by $V = IR$. We can write a similar relation for an inductor:

Reactance where X_L is called the **inductive reactance**. X_L has units of ohms. The quantities V and I in Eq. 21–11a can refer either to rms for both, or to peak values for both (see Section 18–7). Although this equation can relate the peak values, the peak current and voltage are not reached at the same time; so Eq. 21-11a is not valid at a particular instant, as is the case for a resistor $(V = IR)$. Careful calculation (using calculus), as well as experiment, shows that

Inductive reactance

$$
X_L = \omega L = 2\pi f L, \qquad (21-11b)
$$

where $\omega = 2\pi f$ and f is the frequency of the ac.

EXAMPLE 21-16 Reactance of a coil. A coil has a resistance $R = 1.00 \Omega$ and an inductance of 0.300 H. Determine the current in the coil if (a) 120-V dc is applied to it, (b) 120-V ac (rms) at 60.0 Hz is applied.

APPROACH When the voltage is dc, there is no inductive reactance $(X_L = 2\pi fL = 0$ since $f = 0$), so we apply Ohm's law for the resistance. When the voltage is ac, we calculate the reactance X_L and then use Eq. 21-11a.

SOLUTION (a) With dc, we have no X_L so we simply apply Ohm's law:

$$
I = \frac{V}{R} = \frac{120 \text{ V}}{1.00 \Omega} = 120 \text{ A}.
$$

 (b) The inductive reactance is

$$
X_L = 2\pi fL = (6.28)(60.0 \text{ s}^{-1})(0.300 \text{ H}) = 113 \Omega.
$$

In comparison to this, the resistance can be ignored. Thus,

$$
I_{\rm rms} = \frac{V_{\rm rms}}{X_L} = \frac{120 \text{ V}}{113 \Omega} = 1.06 \text{ A}.
$$

NOTE It might be tempting to say that the total impedance is 113 $\Omega + 1\Omega =$ 114 Ω . This might imply that about 1% of the voltage drop is across the resistor, or about 1 V; and that across the inductance is 119 V. Although the 1 V across the resistor is correct, the other statements are not true because of the alteration in phase in an inductor. This will be discussed in the next Section.

* Capacitor

When a capacitor is connected to a battery, the capacitor plates quickly acquire equal and opposite charges; but no steady current flows in the circuit. A capacitor prevents the flow of a dc current. But if a capacitor is connected to an alternating source of voltage, as in Fig. $21-37a$, an alternating current will flow continuously. This can happen because when the ac voltage is first turned on, charge begins to flow and one plate acquires a negative charge and the other a positive charge. But when the voltage reverses itself, the charges flow in the opposite direction. Thus, for an alternating applied voltage, an ac current is present in the circuit continuously.

The applied voltage must equal the voltage across the capacitor: $V = Q/C$, where C is the capacitance and Q the charge on the plates. Thus the charge Q on the plates follows the voltage. But what about the current I ? At point a in Fig. $21-37b$, when the voltage is zero and starts increasing, the charge on the plates is zero. Thus charge flows readily toward the plates and the current I is large. As the voltage approaches its maximum of V_0 (point b), the charge that has accumulated on the plates tends to prevent more charge from flowing, so the current I drops to zero at point b. Thus the current follows the blue curve in Fig. $21-37b$.

FIGURE 21-37 (a) Capacitor connected to an ac source. (b) Current leads voltage by a quarter cycle, or 90°.

CHAPTER 21 Electromagnetic Induction and Faraday's Law 604

Like an inductor, the voltage and current are out of phase by 90° . But for a capacitor, the current reaches its peaks $\frac{1}{4}$ cycle before the voltage does, so we say that the

current leads the voltage by 90° in a capacitor.

Because the current and voltage are out of phase, the average power dissipated is zero, just as for an inductor. Thus only a resistance will dissipate energy as thermal energy in an ac circuit.

A relationship between the applied voltage and the current in a capacitor can be written just as for an inductance:

$$
V = IX_C,
$$
 $\begin{vmatrix} \text{rms or peak} \\ \text{values} \end{vmatrix}$ (21-12a)

where X_C is the **capacitive reactance** and has units of ohms. V and I can both be rms or both maximum (V_0 and I_0); X_c depends on both the capacitance C and the frequency f :

$$
X_C = \frac{1}{\omega C} = \frac{1}{2\pi f C},\tag{21-12b}
$$

where $\omega = 2\pi f$. For dc conditions, $f = 0$ and X_c becomes infinite, as it should because a capacitor does not pass dc current.

EXAMPLE 21-17 Capacitor reactance. What is the rms current in the circuit of Fig. 21-37a if $C = 1.0 \,\mu\text{F}$ and $V_{\text{rms}} = 120 \,\text{V}$? Calculate for (a) $f = 60$ Hz, and then for (b) $f = 6.0 \times 10^5$ Hz.

APPROACH We find the reactance using Eq. 21-12b, and solve for current in the equivalent form of Ohm's law, Eq. 21-12a.

SOLUTION (a) $X_C = 1/2\pi fC = 1/(6.28)(60 \text{ s}^{-1})(1.0 \times 10^{-6} \text{ F}) = 2.7 \text{ k}\Omega$. The rms current is $(Eq. 21-12a)$: \mathbf{V} $120X$

$$
I_{\rm rms} = \frac{V_{\rm rms}}{X_C} = \frac{120 \text{ V}}{2.7 \times 10^3 \Omega} = 44 \text{ mA}
$$

(b) For $f = 6.0 \times 10^5$ Hz, X_c will be 0.27 Ω and $I_{\text{rms}} = 440$ A, vastly larger! **NOTE** The dependence on f is dramatic. For high frequencies, the capacitive reactance is very small.

Two common applications of capacitors are illustrated in Fig. 21-38a and b. In Fig. 21–38a, circuit A is said to be capacitively coupled to circuit B. The purpose of the capacitor is to prevent a dc voltage from passing from A to B but allowing an ac signal to pass relatively unimpeded (if C is sufficiently large). In Fig. 21-38b, the

FIGURE 21-38 (a) (b) Two common uses for a capacitor. (c) Simple loudspeaker cross-over.

capacitor also passes ac but not dc. In this case, a dc voltage can be maintained between circuits A and B, but an ac signal leaving A passes to ground instead of into B. Thus the capacitor in Fig. $21-38b$ acts like a *filter* when a constant dc voltage is required; any sharp variation in voltage will pass to ground instead of into circuit B.

Loudspeakers having separate "woofer" (low-frequency speaker) and "tweeter" (high-frequency speaker) may use a simple "cross-over" that consists of a capacitor in the tweeter circuit to impede low-frequency signals, and an inductor in the woofer circuit to impede high-frequency signals $(X_L = 2\pi fL)$. Hence mainly low-frequency sounds reach and are emitted by the woofer. See Fig. 21-38c.

CAUTION Peak voltages do not add to yield source voltage

FIGURE 21-40 Phasor diagram for a series LRC circuit.

21-13 LRC Series AC Circuit

Let us examine a circuit containing all three elements in series: a resistor R , an inductor L , and a capacitor C , Fig. 21–39. If a given circuit contains only two of these elements, we can still use the results of this Section by setting $R = 0$, $X_L = 0$, or $X_C = 0$, as needed. We let V_R , V_L , and V_C represent the voltage across each element at a *given instant* in time; and V_{R0} , V_{L0} , and V_{C0} represent the maximum (peak) values of these voltages. The voltage across each of the elements will follow the phase relations we discussed in the previous Section. At any instant the voltage V supplied by the source will be, by Kirchhoff's loop rule,

$$
V = V_R + V_L + V_C. \t\t(21-13)
$$

Because the various voltages are not in phase, they do not reach their peak values at the same time, so the peak voltage of the source V_0 will not equal $V_{R0} + V_{L0} + V_{C0}$.

*** Phasor Diagrams**

Let us now examine an LRC circuit in detail. The current at any instant must be the same at all points in the circuit. Thus the currents in each element are in phase with each other, even though the voltages are not. We choose our origin in time $(t = 0)$ so that the current I at any time t is

$$
I = I_0 \cos 2\pi f t
$$

We analyze an LRC circuit using a phasor diagram. Arrows (treated like vectors) are drawn in an xy coordinate system to represent each voltage. The length of each arrow represents the magnitude of the peak voltage across each element:

$$
V_{R0} = I_0 R
$$
, $V_{L0} = I_0 X_L$, and $V_{C0} = I_0 X_C$

 V_{R0} is in phase with the current and is initially ($t = 0$) drawn along the positive x axis, as is the current. V_{L0} leads the current by 90°, so it leads V_{R0} by 90° and is initially drawn along the positive y axis. V_{C0} lags the current by 90°, so V_{C0} is drawn initially along the negative y axis. See Fig. 21-40a. If we let the vector diagram rotate counterclockwise at frequency f , we get the diagram shown in Fig. 21–40b; after a time, t, each arrow has rotated through an angle $2\pi ft$. Then the projections of each arrow on the x axis represent the voltages across each element at the instant t (Fig. 21–40c). For example $I = I_0 \cos 2\pi ft$.

The sum of the projections of the three voltage vectors represents the instantaneous voltage across the whole circuit, V. Therefore, the vector sum of these vectors will be the vector that represents the peak source voltage, V_0 , as shown in Fig. 21–41 where it is seen that V_0 makes an angle ϕ with I_0 and V_{R0} . As time passes, V_0 rotates with the other vectors, so the instantaneous voltage V (projection of V_0 on the x axis) is (see Fig. 21–41)

$$
V = V_0 \cos(2\pi f t + \phi).
$$

The voltage V across the whole circuit must, of course, equal the source voltage (Fig. $21-39$). Thus the voltage from the source is out of phase with the current by an angle ϕ .

From this analysis we can now determine the total **impedance** Z of the circuit, which is defined by the relation

$$
V_{\text{rms}} = I_{\text{rms}} Z
$$
, or $V_0 = I_0 Z$. (21-14)

From Fig. 21–41 we see, using the Pythagorean theorem (V_0 is the hypotenuse of

a right triangle), that

$$
V_0 = \sqrt{V_{R0}^2 + (V_{L0} - V_{C0})^2}
$$

= $I_0 \sqrt{R^2 + (X_L - X_C)^2}$.

Thus, from Eq. $21-14$, the total impedance Z is

$$
Z=\sqrt{R^2+\left(X_L-X_C\right)^2}.
$$

Also from Fig. 21–41, we can find the phase angle ϕ between voltage and current:

$$
\tan \phi = \frac{V_{L0} - V_{C0}}{V_{R0}} = \frac{I_0(X_L - X_C)}{I_0 R} = \frac{X_L - X_C}{R}
$$
 (21-16a)

and

$$
\cos \phi = \frac{V_{R0}}{V_0} = \frac{I_0 R}{I_0 Z} = \frac{R}{Z}.
$$
 (21-16b)

Figure 21-41 was drawn for the case $X_L > X_C$, and the current lags the source voltage by ϕ . When the reverse is true, $X_L < X_C$, then ϕ in Eqs. 21–16 is less than zero, and the current leads the source voltage.

We saw earlier that power is dissipated only by a resistance; none is dissipated by inductance or capacitance. Therefore, the average power $\overline{P} = I_{rms}^2 R$. But from Eq. 21–16b, $R = Z \cos \phi$. Therefore

$$
\overline{P} = I_{\rm rms}^2 Z \cos \phi = I_{\rm rms} V_{\rm rms} \cos \phi.
$$
 (21–17) *Power factor*

 $(21-15)$

Total impedance

The factor $\cos \phi$ is referred to as the *power factor* of the circuit.

EXAMPLE 21-18 LRC circuit. Suppose $R = 25.0 \Omega$, $L = 30.0 \text{ mH}$, and $C = 12.0 \,\mu\text{F}$ in Fig. 21–39, and they are connected to a 90.0-V ac (rms) 500-Hz source. Calculate (a) the current in the circuit, and (b) the voltmeter readings (rms) across each element.

APPROACH To obtain the current, we need to determine the impedance (Eq. 21–15 plus Eqs. 21–11b and 21–12b), and then use $I_{\text{rms}} = V_{\text{rms}}/Z$. Voltage drops across each element are found using Ohm's law or equivalent for each element: $V_R = IR$, $V_L = IX_L$, and $V_C = IX_C$.

SOLUTION (a) First, we find the reactance of the inductor and capacitor at $f = 500$ Hz = 500 s⁻¹:

$$
X_L = 2\pi f L = 94.2 \Omega
$$
, $X_C = \frac{1}{2\pi f C} = 26.5 \Omega$.

Then the total impedance is

$$
Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(25.0 \,\Omega)^2 + (94.2 \,\Omega - 26.5 \,\Omega)^2} = 72.2 \,\Omega.
$$

From the impedance version of Ohm's law, Eq. 21–14,

$$
I_{\rm rms} = \frac{V_{\rm rms}}{Z} = \frac{90.0 \,\mathrm{V}}{72.2 \,\Omega} = 1.25 \,\mathrm{A}.
$$

 (b) The rms voltage across each element is

$$
(V_R)_{\text{rms}} = I_{\text{rms}} R = (1.25 \text{ A})(25.0 \Omega) = 31.2 \text{ V}
$$

\n
$$
(V_L)_{\text{rms}} = I_{\text{rms}} X_L = (1.25 \text{ A})(94.2 \Omega) = 118 \text{ V}
$$

\n
$$
(V_C)_{\text{rms}} = I_{\text{rms}} X_C = (1.25 \text{ A})(26.5 \Omega) = 33.1 \text{ V}.
$$

NOTE These voltages do *not* add up to the source voltage, 90.0 V (rms). Indeed, the rms voltage across the inductance *exceeds* the source voltage. This can happen because the different voltages are out of phase with each other, and at any instant one voltage can be negative, to compensate for a large positive voltage of another. The rms voltages, however, are always positive by definition. Although the rms voltages need not add up to the source voltage, the instantaneous voltages at any time must add up to the source voltage at that instant.

FIGURE 21-42 Current in an LRC circuit as a function of frequency, showing resonance peak at $f = f_0 = (1/2\pi)\sqrt{1/LC}$.

Resonant frequency

LC circuit

EM oscillations

14 Resonance in AC Circuits

The rms current in an LRC series circuit is given by (see Eqs. 21-14, 21-15, $21 - 11b$, and $21 - 12b$):

$$
I_{\rm rms} = \frac{V_{\rm rms}}{Z} = \frac{V_{\rm rms}}{\sqrt{R^2 + \left(2\pi fL - \frac{1}{2\pi fC}\right)^2}}.
$$
 (21-18)

Because the reactance of inductors and capacitors depends on the frequency f of the source, the current in an LRC circuit depends on frequency. From Eq. $21-18$ we see that the current will be maximum at a frequency that satisfies

$$
2\pi fL - \frac{1}{2\pi fC} = 0.
$$

We solve this for f, and call the solution f_0 :

$$
f_0 = \frac{1}{2\pi} \sqrt{\frac{1}{LC}}.
$$
 (21-19)

When $f = f_0$, the circuit is in resonance, and f_0 is the **resonant frequency** of the circuit. At this frequency, $X_C = X_L$, so the impedance is purely resistive. A graph of I_{rms} versus f is shown in Fig. 21–42 for particular values of R, L, and C. For smaller R compared to X_L and X_C , the resonance peak will be higher and sharper.

When R is very small, we speak of an LC circuit. The energy in an LC circuit oscillates, at frequency f_0 , between the inductor and the capacitor, with some being dissipated in R (some resistance is unavoidable). This is called an LC oscillation or an electromagnetic oscillation. Not only does the charge oscillate back and forth, but so does the energy, which oscillates between being stored in the electric field of the capacitor and in the magnetic field of the inductor.

Electric resonance is used in many circuits. Radio and TV sets, for example, use resonant circuits for tuning in a station. Many frequencies reach the circuit from the antenna, but a significant current flows only for frequencies at or near the resonant frequency. Either L or C is variable so that different stations can be tuned in (more on this in Chapter 22).

Summary

The magnetic flux passing through a loop is equal to the product of the area of the loop times the perpendicular component of the magnetic field strength:

$$
\Phi_B = B_\perp A = BA \cos \theta. \tag{21-1}
$$

If the magnetic flux through a coil of wire changes in time, an emf is induced in the coil. The magnitude of the induced emf equals the time rate of change of the magnetic flux through the loop times the number N of loops in the coil:

$$
\delta = -N \frac{\Delta \Phi_B}{\Delta t}.
$$
 (21-2b)

This is Faraday's law of induction.

É

The induced emf can produce a current whose magnetic field opposes the original change in flux (Lenz's law).

Faraday's law also tells us that a changing magnetic field produces an electric field; and that a straight wire of length l moving with speed v perpendicular to a magnetic field of strength B has an emf induced between its ends equal to

$$
\mathscr{E} = Blv. \tag{21-3}
$$

An electric generator changes mechanical energy into electrical energy. Its operation is based on Faraday's law: a coil of wire is made to rotate uniformly by mechanical means in a magnetic field, and the changing flux through the coil induces a sinusoidal current, which is the output of the generator.

[*A motor, which operates in the reverse of a generator, acts like a generator in that a back emf, or counter emf, is induced in its rotating coil. Because this back emf opposes the input voltage, it can act to limit the current in a motor coil. Similarly, a generator acts somewhat like a motor in that a counter torque acts on its rotating coil.]

A transformer, which is a device to change the magnitude of an ac voltage, consists of a primary coil and a secondary coil. The changing flux due to an ac voltage in the primary coil induces an ac voltage in the secondary coil. In a 100% efficient transformer, the ratio of output to input voltages (V_S/V_P) equals the ratio of the number of turns N_S in the secondary to the number N_{P} in the primary:

$$
\frac{V_{\rm S}}{V_{\rm P}} = \frac{N_{\rm S}}{N_{\rm P}}.\tag{21-6}
$$

The ratio of secondary to primary current is in the inverse ratio of turns:

$$
\frac{I_{\rm S}}{I_{\rm P}} = \frac{N_{\rm P}}{N_{\rm S}}.\tag{21-7}
$$

608 CHAPTER 21 Electromagnetic Induction and Faraday's Law

Microphones, ground fault circuit interrupters, seismographs, and read/write heads for computer drives and tape recorders are applications of electromagnetic induction.

[*A changing current in a coil of wire will produce a changing magnetic field that induces an emf in a second coil placed nearby. The **mutual inductance**, M , is defined by

$$
\mathcal{E}_2 = -M \frac{\Delta I_1}{\Delta t} \tag{21-8}
$$

[*Within a single coil, the changing B due to a changing current induces an opposing emf, %, so a coil has a self-inductance L defined by

$$
\xi = -L \frac{\Delta I}{\Delta t}.
$$
 (21-9)

[*The energy stored in an inductance L carrying current I is given by $U = \frac{1}{2}LI^2$. This energy can be thought of as being stored in the magnetic field of the inductor. The energy density u in any magnetic field B is given by

$$
u = \frac{1}{2} \frac{B^2}{\mu_0}.
$$
 (21-10)

[*When an inductance L and resistor R are connected in series to a source of emf, V , the current rises as

$$
I = \frac{V}{R} \left(1 - e^{-t/\tau} \right),
$$

where $\tau = L/R$ is the time constant. If the battery is suddenly switched out of the LR circuit, the current drops exponentially, $I = I_{\text{max}} e^{-t/\tau}$.]

[*Inductive and capacitive reactance, X , defined as for resistors, is the proportionality constant between voltage and current (either the rms or peak values). Across an inductor,

$$
V = IX_L, \tag{21-11a}
$$

and across a capacitor,

$$
V = IX_C. \tag{21-12a}
$$

The reactance of an inductor increases with frequency

$$
X_L = 2\pi f L, \tag{21-11b}
$$

whereas the reactance of a capacitor decreases with frequency f .

$$
X_C = \frac{1}{2\pi f C}.
$$
 (21-12b)

The current through a resistor is always in phase with the voltage across it, but in an inductor, the current lags the voltage by 90°, and in a capacitor the current leads the voltage by 90°.]

[*In an *LRC* series circuit, the total **impedance** Z is defined by the equivalent of $V = IR$ for resistance, namely,

$$
V_0 = I_0 Z \quad \text{or} \quad V_{\text{rms}} = I_{\text{rms}} Z; \tag{21-14}
$$

Z is given by

$$
Z = \sqrt{R^2 + (X_L - X_C)^2}.
$$
 (21-15a)

[*An *LRC* series circuit **resonates** at a frequency given by

$$
f_0 = \frac{1}{2\pi} \sqrt{\frac{1}{LC}}.
$$
 (21-19)

The rms current in the circuit is largest when the applied voltage has a frequency equal to f_0 .]

Questions

- 1. What would be the advantage, in Faraday's experiments (Fig. 21-1), of using coils with many turns?
- 2. What is the difference between magnetic flux and magnetic field?
- 3. Suppose you are holding a circular ring of wire and suddenly thrust a magnet, south pole first, away from you toward the center of the circle. Is a current induced in the wire? Is a current induced when the magnet is held steady within the ring? Is a current induced when you withdraw the magnet? In each case, if your answer is yes, specify the direction.
- 4. Two loops of wire are moving in the vicinity of a very long straight wire carrying a steady current as shown in Fig. 21-43. Find the direction of the induced current in each loop.

5. Suppose you are looking along a line through the centers of two circular (but separate) wire loops, one behind the other. A battery is suddenly connected to the front loop, establishing a clockwise current. (a) Will a current be induced in the second loop? (b) If so, when does this current start? (c) When does it stop? (d) In what direction is this current? (e) Is there a force between the two loops? (f) If so, in what direction?

6. In Fig. $21-44$, determine the direction of the induced current in resistor R_A when (a) coil B is moved toward coil A, (b) when coil B is moved away from A, (c) when the resistance R_B is increased.

FIGURE 21-44 Ouestion 6.

- 7. In situations where a small signal must travel over a distance, a "shielded cable" is used in which the signal wire is surrounded by an insulator and then enclosed by a cylindrical conductor carrying the return current. Why is a "shield" necessary?
- 8. What is the advantage of placing the two insulated electric wires carrying ac close together or even twisted about each other?
- *9. Explain why, exactly, the lights may dim briefly when a refrigerator motor starts up. When an electric heater is turned on, the lights may stay dimmed as long as the heater is on. Explain the difference.
- $*$ 10. Use Figs. 21-15 and 21-17 plus the right-hand rules to show why the counter torque in a generator *opposes* the motion.
- * 11. Will an eddy current brake (Fig. 21–20) work on a copper or aluminum wheel, or must the wheel be ferromagnetic? Explain.
- *12. It has been proposed that eddy currents be used to help sort solid waste for recycling. The waste is first ground into tiny pieces and iron removed with a dc magnet. The waste then is allowed to slide down an incline over permanent magnets. How will this aid in the separation of nonferrous metals (Al, Cu, Pb, brass) from nonmetallic materials?
- *13. The pivoted metal bar with slots in Fig. 21-45 falls much more quickly through a magnetic field than does a solid bar. Explain.

FIGURE 21-45 Ouestion 13.

- * 14. If an aluminum sheet is held between the poles of a large bar magnet, it requires some force to pull it out of the magnetic field even though the sheet is not ferromagnetic and does not touch the pole faces. Explain.
- * 15. A bar magnet falling inside a vertical metal tube reaches a terminal velocity even if the tube is evacuated so that there is no air resistance. Explain.
- * 16. A metal bar, pivoted at one end, oscillates freely in the absence of a magnetic field; but in a magnetic field, its oscillations are quickly damped out. Explain. (This magnetic damping is used in a number of practical devices.)
	- 17. An enclosed transformer has four wire leads coming from it. How could vou determine the ratio of turns on the two coils without taking the transformer apart? How would you know which wires paired with which?
	- 18. The use of higher-voltage lines in homes—say, 600 V or 1200 V-would reduce energy waste. Why are they not used?
	- 19. A transformer designed for a 120-V ac input will often "burn out" if connected to a 120-V dc source. Explain. [*Hint*: the resistance of the primary coil is usually very low.]
- * 20. How would vou arrange two flat circular coils so that their mutual inductance was (a) greatest, (b) least (without separating them by a great distance)?
- * 21. Does the emf of the battery in Fig. 21-33 affect the time needed for the LR circuit to reach (a) a given fraction of its maximum possible current, (b) a given value of current? Explain.
- $*$ 22. In an *LRC* circuit, can the rms voltage across (a) an inductor, (b) a capacitor, be greater than the rms voltage of the ac source? Explain.
- *23. Describe briefly how the frequency of the source emf affects the impedance of (a) a pure resistance, (b) a pure capacitance, (c) a pure inductance, (d) an LRC circuit near resonance $(R \text{ small})$, (e) an *LRC* circuit far from resonance $(R \text{ small})$.
- * 24. Describe how to make the impedance in an LRC circuit a minimum.

Problems

21-1 to 21-4 Faraday's Law of Induction

- 1. (I) The magnetic flux through a coil of wire containing two loops changes from -50 Wb to $+38$ Wb in 0.42 s. What is the emf induced in the coil?
- 2. (I) The rectangular loop shown in Fig. $21-46$ is pushed into the magnetic field which points inward. In what direction is the induced current?

3. (I) The north pole of the magnet in Fig. $21-47$ is being inserted into the coil. In which direction is the induced current flowing through the resistor R ?

- 4. (I) A 9.6-cm-diameter circular loop of wire is in a 1.10-T magnetic field. The loop is removed from the field in 0.15 s. What is the average induced emf?
- 5. (I) A 12.0-cm-diameter loop of wire is initially oriented perpendicular to a 1.5-T magnetic field. The loop is rotated so that its plane is parallel to the field direction in 0.20 s. What is the average induced emf in the loop?
- 6. (II) A 10.2-cm-diameter wire coil is initially oriented so that its plane is perpendicular to a magnetic field of 0.63 T pointing up. During the course of 0.15 s, the field is changed to one of 0.25 T pointing down. What is the average induced emf in the coil?
- 7. (II) A 15-cm-diameter circular loop of wire is placed in a 0.50 -T magnetic field. (*a*) When the plane of the loop is perpendicular to the field lines, what is the magnetic flux through the loop? (b) The plane of the loop is rotated until it makes a 35° angle with the field lines. What is the angle θ in Eq. 21-1 for this situation? (c) What is the magnetic flux through the loop at this angle?

8. (II) (a) If the resistance of the resistor in Fig. 21–48 is slowly increased, what is the direction of the current induced in the small circular loop inside the larger loop? (b) What would it be if the small loop were placed outside the larger one, to the left?

9. (II) What is the direction of the induced current in the circular loop due to the current shown in each part of Fig. 21-49?

10. (II) If the solenoid in Fig. $21-50$ is being pulled away from the loop shown, in what direction is the induced current in the loop?

FIGURE 21-50 Problem 10.

- 11. (II) The magnetic field perpendicular to a circular wire loop 12.0 cm in diameter is changed from $+0.52$ T to -0.45 T in 180 ms, where + means the field points away from an observer and $-$ toward the observer. (a) Calculate the induced emf. (b) In what direction does the induced current flow?
- 12. (II) The moving rod in Fig. $21-12$ is 12.0 cm long and is pulled at a speed of 15.0 cm/s. If the magnetic field is 0.800 T, calculate (a) the emf developed, and (b) the electric field felt by electrons in the rod.
- 13. (II) A circular loop in the plane of the paper lies in a 0.75-T magnetic field pointing into the paper. If the loop's diameter changes from 20.0 cm to 6.0 cm in 0.50 s, (a) what is the direction of the induced current, (b) what is the magnitude of the average induced emf, and (c) if the coil resistance is 2.5Ω , what is the average induced current?
- 14. (II) The moving rod in Fig. 21-12 is 13.2 cm long and generates an emf of 120 mV while moving in a 0.90-T magnetic field. (a) What is its speed? (b) What is the electric field in the rod?
- 15. (II) Part of a single rectangular loop of wire with dimensions shown in Fig. $21-51$ is situated inside a region of uniform magnetic field of 0.550 T. The total resistance of the loop is 0.230Ω . Calculate the force required to pull the loop from the field (to the right) at a constant velocity of 3.40 m/s. Neglect gravity.

FIGURE 21-51 Problem 15.

- 16. (II) A 500-turn solenoid, 25 cm long, has a diameter of 2.5 cm. A 10-turn coil is wound tightly around the center of the solenoid. If the current in the solenoid increases uniformly from 0 to 5.0 A in 0.60 s , what will be the induced emf in the short coil during this time?
- 17. (II) In Fig. 21–12, the rod moves with a speed of 1.6 m/s , is 30.0 cm long, and has a resistance of 2.5Ω . The magnetic field is 0.35 T, and the resistance of the U-shaped conductor is 25.0Ω at a given instant. Calculate (a) the induced emf, (b) the current in the U-shaped conductor, and (c) the external force needed to keep the rod's velocity constant at that instant.
- 18. (III) A 22.0-cm-diameter coil consists of 20 turns of circular copper wire 2.6 mm in diameter. A uniform magnetic field, perpendicular to the plane of the coil, changes at a rate of 8.65×10^{-3} T/s. Determine (*a*) the current in the loop, and (b) the rate at which thermal energy is produced.
- 19. (III) The magnetic field perpendicular to a single 13.2-cmdiameter circular loop of copper wire decreases uniformly from 0.750 T to zero. If the wire is 2.25 mm in diameter, how much charge moves past a point in the coil during this operation?

21-5 Generators

20. (I) A simple generator is used to generate a peak output voltage of 24.0 V. The square armature consists of windings that are 6.0 cm on a side and rotates in a field of 0.420 T at a rate of 60.0 rev/s. How many loops of wire should be wound on the square armature?

- $21.$ (II) The generator of a car idling at 1100 rpm produces 12.4 V. What will the output be at a rotation speed of 2500 rpm, assuming nothing else changes?
- 22. (II) Show that the rms output (Section 18-7) of an ac generator is $V_{\text{rms}} = NAB\omega/\sqrt{2}$, where $\omega = 2\pi f$.
- 23. (II) A simple generator has a 320-loop square coil 21.0 cm on a side. How fast must it turn in a 0.650-T field to produce a 120-V peak output?
- 24. (II) A 450-loop circular armature coil with a diameter of 8.0 cm rotates at 120 rev/s in a uniform magnetic field of strength 0.55 T. (*a*) What is the rms voltage output of the generator? (b) What would you do to the rotation frequency in order to double the rms voltage output?
- 25. (II) A generator rotates at 85 Hz in a magnetic field of 0.030 T. It has 1000 turns and produces an rms voltage of $150V$ and an rms current of 70.0 A. (a) What is the peak current produced? (b) What is the area of each turn of the coil?

* 21-6 Back EMF and Torque

- $*26$. (I) A motor has an armature resistance of 3.25 Ω . If it draws 8.20 A when running at full speed and connected to a 120-V line, how large is the back emf?
- $*$ 27. (I) The back emf in a motor is 72 V when operating at 1800 rpm. What would be the back emf at 2500 rpm if the magnetic field is unchanged?
- * 28. (II) The back emf in a motor is 95 V when the motor is operating at 1000 rpm. How would you change the motor's magnetic field if you wanted to reduce the back emf to 65 V when the motor was running at 2500 rpm?
- * 29. (II) What will be the current in the motor of Example 21-9 if the load causes it to run at half speed?

21-7 Transformers

[Assume 100% efficiency, unless stated otherwise.]

- 30. (I) A transformer is designed to change $120V$ into 10,000 V, and there are 164 turns in the primary coil. How many turns are in the secondary coil?
- 31. (I) A transformer has 320 turns in the primary coil and 120 in the secondary coil. What kind of transformer is this, and by what factor does it change the voltage? By what factor does it change the current?
- 32. (I) A step-up transformer increases 25 V to 120 V . What is the current in the secondary coil as compared to the primary coil?
- 33. (I) Neon signs require $12 \, \text{kV}$ for their operation. To operate from a 240-V line, what must be the ratio of secondary to primary turns of the transformer? What would the voltage output be if the transformer were connected backward?
- 34. (II) A model-train transformer plugs into 120-V ac and draws 0.35 A while supplying 7.5 A to the train. (a) What voltage is present across the tracks? (b) Is the transformer step-up or step-down?
- 35. (II) The output voltage of a 95-W transformer is 12 V, and the input current is $22 A. (a)$ Is this a step-up or a step-down transformer? (b) By what factor is the voltage multiplied?
- 36. (II) A transformer has 330 primary turns and 1340 secondary turns. The input voltage is $120V$ and the output current is 15.0 A. What are the output voltage and input current?
- 37. (II) If 30 MW of power at 45 kV (rms) arrives at a town from a generator via $4.0-\Omega$ transmission lines, calculate (a) the emf at the generator end of the lines, and (b) the fraction of the power generated that is wasted in the lines.
- 38. (III) 65 kW is to arrive at a town over two 0.100- Ω lines. Estimate how much power is saved if the voltage is stepped up from $120V$ to $1200V$ and then down again, rather than simply transmitting at 120 V. Assume the transformers are each 99% efficient.

* 21-9 Inductance

- *39. (I) If the current in a 180-mH coil changes steadily from 25.0 A to 10.0 A in 350 ms, what is the magnitude of the induced emf?
- * 40. (I) What is the inductance of a coil if the coil produces an emf of 2.50 V when the current in it changes from -28.0 mA to $+31.0$ mA in 12.0 ms?
- $*$ 41. (I) What is the inductance L of a 0.60-m-long air-filled coil 2.9 cm in diameter containing 10,000 loops?
- *42. (I) How many turns of wire would be required to make a 130-mH inductance out of a 30.0-cm-long air-filled coil with a diameter of 5.2 cm?
- *43. (II) An air-filled cylindrical inductor has 2800 turns, and it is 2.5 cm in diameter and 28.2 cm long. (a) What is its inductance? (b) How many turns would you need to generate the same inductance if the core were iron-filled instead? Assume the magnetic permeability of iron is about 1200 times that of free space.
- * 44. (II) A coil has $2.25-\Omega$ resistance and 440-mH inductance. If the current is 3.00 A and is increasing at a rate of 3.50 A/s, what is the potential difference across the coil at this moment?
- *45. (III) A long thin solenoid of length l and cross-sectional area A contains N_1 closely packed turns of wire. Wrapped tightly around it is an insulated coil of N_2 turns, Fig. 21-52. Assume all the flux from coil 1 (the solenoid) passes through coil 2, and calculate the mutual inductance.

FIGURE 21-52 Problem 45.

*46. (III) The wire of a tightly wound solenoid is unwound and used to make another tightly wound solenoid of twice the diameter. By what factor does the inductance change?

* 21-10 Magnetic Energy Storage

- *47. (I) The magnetic field inside an air-filled solenoid 36 cm long and 2.0 cm in diameter is 0.80 T. Approximately how much energy is stored in this field?
- *48. (II) At a given instant the current through an inductor is 50.0 mA and is increasing at the rate of 115 mA/s . What is the initial energy stored in the inductor if the inductance is known to be 60.0 mH, and how long does it take for the energy to increase by a factor of 10 from the initial value?

*49. (II) Assuming the Earth's magnetic field averages about 0.50×10^{-4} T near the surface of the Earth, estimate the total energy stored in this field in the first 10 km above the Earth's surface.

$*$ 21-11 LR Circuit

- * 50. (II) Determine $\Delta I/\Delta t$ at $t = 0$ (when the battery is connected) for the LR circuit of Fig. $21-33$ and show that if I continued to increase at this rate, it would reach its maximum value in one time constant.
- * 51. (III) After how many time constants does the current in Fig. 21–33 reach within (a) 10%, (b) 1.0%, and (c) 0.1% of its maximum value?
- *52. (III) Two tightly wound solenoids have the same length and circular cross-sectional area. But solenoid 1 uses wire that is half as thick as solenoid 2. (a) What is the ratio of their inductances? (b) What is the ratio of their inductive time constants (assuming no other resistance in the circuits)?

* 21-12 AC Circuits and Reactance

- *53. (I) What is the reactance of a 7.20- μ F capacitor at a frequency of (*a*) 60.0 Hz, (*b*) 1.00 MHz?
- *54. (I) At what frequency will a 22.0-mH inductor have a reactance of 660 Ω ?
- $*55$. (I) At what frequency will a 2.40- μ F capacitor have a reactance of 6.70 k Ω ?
- *56. (II) Plot a graph of the reactance of a 1.0- μ F capacitor as a function of frequency from 10 to 1000 Hz.
- $*57$. (II) Plot a graph of the reactance of a 1.0-mH inductor as a function of frequency from 100 to 10,000 Hz.
- *58. (II) Calculate the reactance of, and rms current in, a 160-mH radio coil connected to a 240-V (rms) 10.0-kHz ac line. Ignore resistance.
- \approx 59. (II) An inductance coil operates at 240 V and 60.0 Hz. It draws 12.8 A. What is the coil's inductance?
- $*60.$ (II) (a) What is the reactance of a well-insulated $0.030 \text{-} \mu$ F capacitor connected to a 2.0-kV (rms) 720-Hz line? (b) What will be the peak value of the current?

General Problems

72. Suppose you are looking at two current loops in the plane of the page as shown in Fig. $21-53$. When switch S is thrown in the left-hand coil, (a) what is the direction of the induced current in the other loop? (b) What is the situation after a "long" time? (c) What is the direction of the induced current in the right-hand loop if that loop is quickly pulled horizontally to the right?

FIGURE 21-53

Problem 72.

* 21-13 LRC Circuits

- $*61.$ (I) A 30-k Ω resistor is in series with a 45-mH inductor and an ac source. Calculate the impedance of the circuit if the source frequency is (a) 50 Hz, and (b) 3.0×10^4 Hz.
- * 62. (I) A 3.5-kΩ resistor and a 4.0- μ F capacitor are connected in series to an ac source. Calculate the impedance of the circuit if the source frequency is (a) 60 Hz, and (b) 60,000 Hz.
- $*$ 63. (I) For a 120-V rms 60-Hz voltage, an rms current of 70 mA passing through the human body for 1.0 s could be lethal. What must be the impedance of the body for this to occur?
- * 64. (II) What is the resistance of a coil if its impedance is 235 Ω and its reactance is 135 Ω ?
- * 65. (II) What are the total impedance, phase angle, and rms current in an LRC circuit connected to a 10.0-kHz, 725-V (rms) source if $L = 22.0$ mH, $R = 8.70$ k Ω , and $C = 6250 \text{ pF}$?
- $*66.$ (III) A 2.5-k Ω resistor in series with a 420-mH inductor is driven by an ac power supply. At what frequency is the impedance double that of the impedance at 60 Hz?
- $*$ 67. (III) (a) What is the rms current in an RL circuit when a 60.0-Hz 120-V rms ac voltage is applied, where $R = 1.80 \text{ k}\Omega$, and $L = 350 \text{ mH}$? (b) What is the phase angle between voltage and current? (c) What are the rms voltage readings across R and L ?
- * 68. (III) (a) What is the rms current in an RC circuit if $R = 8.80 \text{ k}\Omega$, $C = 1.80 \mu\text{F}$, and the rms applied voltage is 120 V at 60.0 Hz ? (b) What is the phase angle between voltage and current? (c) What are the voltmeter readings across R and C ?

* 21-14 Resonance in AC Circuits

- * 69. (I) A 3500-pF capacitor is connected to a 55.0- μ H coil of resistance 3.00 Ω . What is the resonant frequency of this circuit?
- * 70. (I) The variable capacitor in the tuner of an AM radio has a capacitance of 2800 pF when the radio is tuned to a station at 580 kHz. (*a*) What must be the capacitance for a station at 1600 kHz? (b) What is the inductance (assumed constant)?
- * 71. (II) An *LRC* circuit has $L = 14.8$ mH and $R = 4.40 \Omega$. (a) What value must C have to produce resonance at 3600 Hz? (b) What will be the maximum current at resonance if the peak external voltage is 150 V?
- 73. A square loop 24.0 cm on a side has a resistance of 5.20 Ω . It is initially in a 0.665-T magnetic field, with its plane perpendicular to \vec{B} , but is removed from the field in 40.0 ms. Calculate the electric energy dissipated in this process.
- 74. A high-intensity desk lamp is rated at 45 W but requires only 12 V. It contains a transformer that converts 120-V household voltage. (a) Is the transformer step-up or step-down? (b) What is the current in the secondary coil when the lamp is on? (c) What is the current in the primary coil? (d) What is the resistance of the bulb when on?
- 75. Power is generated at 24 kV at a generating plant located 118 km from a town that requires 50 MW of power at 12 kV. Two transmission lines from the plant to the town each have a resistance of $0.10 \Omega/km$. What should the output voltage of the transformer at the generating plant be for an overall transmission efficiency of 98.5%, assuming a perfect transformer?
- 76. The primary windings of a transformer which has an 80% efficiency are connected to 110-V ac. The secondary windings are connected across a $2.4-\Omega$, 75-W lightbulb. (a) Calculate the current through the primary windings of the transformer. (b) Calculate the ratio of the number of primary windings of the transformer to the number of secondary windings of the transformer.
- 77. A pair of power transmission lines each have a $0.80-\Omega$ resistance and carry 740 A over 9.0 km. If the rms input voltage is 42 kV, calculate (*a*) the voltage at the other end, (b) the power input, (c) power loss in the lines, and (d) the power output.
- 78. Two resistanceless rails rest 32 cm apart on a 6.0° ramp. They are joined at the bottom by a $0.60 - \Omega$ resistor. At the top a copper bar of mass 0.040 kg (ignore its resistance) is laid across the rails. The whole apparatus is immersed in a vertical 0.55-T field. What is the terminal (steady) velocity of the bar as it slides frictionlessly down the rails?
- 79. Show that the power loss in transmission lines, P_L , is given by $P_L = (P_T)^2 R_L/V^2$, where P_T is the power transmitted to the user, V is the delivered voltage, and R_L is the resistance of the power lines.
- 80. A coil with 150 turns, a radius of 5.0 cm, and a resistance of 12 Ω surrounds a solenoid with 230 turns/cm and a radius of 4.5 cm; see Fig. 21-54. The current in the solenoid changes at a constant rate from 0 to 2.0 A in 0.10 s. Calculate the magnitude and direction of the induced current in the coil.

FIGURE 21-54 Problem 80.

- 81. A certain electronic device needs to be protected against sudden surges in current. In particular, after the power is turned on the current should rise no more than 7.5 mA in the first 120 μ s. The device has resistance 150 Ω and is designed to operate at 55 mA. How would you protect this device?
- 82. A 25-turn 12.5-cm-diameter coil is placed between the pole pieces of an electromagnet. When the magnet is turned on, the flux through the coil changes, inducing an emf. At what rate (in T/s) must the field produced by the magnet change if the emf is to be 120 V?
- $*83.$ Calculate the peak output voltage of a simple generator whose square armature windings are 6.60 cm on a side; the armature contains 155 loops and rotates in a field of 0.200 T at a rate of 120 rev/s.
- *84. Typical large values for electric and magnetic fields attained in laboratories are about 1.0×10^4 V/m and 2.0 T. (a) Determine the energy density for each field and compare. (b) What magnitude electric field would be needed to produce the same energy density as the 2.0-T magnetic field?
- $*85$. What is the inductance L of the primary of a transformer whose input is $220V$ at $60.0 Hz$ if the current drawn is 5.8 A? Assume no current in the secondary.
- * 86. A 130-mH coil whose resistance is 18.5Ω is connected to a capacitor C and a 1360-Hz source voltage. If the current and voltage are to be in phase, what value must C have?
- *87. An inductance coil draws 2.5-A dc when connected to a 36-V battery. When connected to a 60-Hz 120-V (rms) source, the current drawn is 3.8 A (rms). Determine the inductance and resistance of the coil.
- * 88. A 135-mH inductor with $2.0-\Omega$ resistance is connected in series to a $20-\mu$ F capacitor and a 60-Hz, 45-V source. Calculate (a) the rms current, and (b) the phase angle.
- $*89$. The Q factor of a resonance circuit can be defined as the ratio of the voltage across the capacitor (or inductor) to the voltage across the resistor, at resonance. The larger the Q factor, the sharper the resonance curve will be and the sharper the tuning. (a) Show that the Q factor is given by the equation $Q = (1/R)\sqrt{L/C}$. (b) At a resonant frequency $f_0 = 1.0$ MHz, what must be the values of L and R to produce a Q factor of 550? Assume that $C = 0.010 \,\mu\text{F}.$

Answers to Exercises

A: 0.0102 Wb.

B: (a) Counterclockwise; (b) clockwise; (c) zero; (d) counterclockwise.

C: Counterclockwise. $D: 10$ turns.

These circular disk antennas, each 25 m in diameter, are pointed to receive radio waves from out in space. Radio waves are electromagnetic (EM) waves that have frequencies from a few hundred Hz to about 100 MHz. These antennas are connected together electronically to achieve better detail, and are a part of the Very Large Array in New Mexico searching the heavens for information about the Cosmos.

Maxwell predicted the existence of EM waves from his famous equations, which are a magnificent summary of electromagnetism.

CHAPTER,

Electromagnetic Waves

FIGURE 22-1 James Clerk Maxwell.

The culmination of electromagnetic theory in the nineteenth century was the prediction, and the experimental verification, that waves of electromagnetic fields could travel through space. This achievement opened a whole new world of communication: first the wireless telegraph, then radio and television, and more recently cell phones and remote-control devices. And it vielded the spectacular prediction that light is an electromagnetic wave.

The theoretical prediction of electromagnetic waves was the work of the Scottish physicist James Clerk Maxwell (1831-1879; Fig. 22-1), who unified, in one magnificent theory, all the phenomena of electricity and magnetism.

22-1 Changing Electric Fields Produce **Magnetic Fields: Maxwell's Equations**

The development of electromagnetic theory in the early part of the nineteenth century by Oersted, Ampère, and others was not actually done in terms of electric and magnetic fields. The idea of the field was introduced somewhat later by Faraday, and was not generally used until Maxwell showed that all electric and magnetic phenomena could be described using only four equations involving electric and magnetic fields. These equations, known as **Maxwell's equations**, are the basic equations for all electromagnetism. They are fundamental in the same sense that Newton's three laws of motion and the law of universal gravitation are for mechanics. In a sense, they are even more fundamental, because they are consistent with the theory of relativity (Chapter 26), whereas Newton's laws are not. Because all of electromagnetism is contained in this set of four equations, Maxwell's equations are considered one of the great triumphs of the human intellect.

Although we will not present Maxwell's equations in mathematical form since they involve calculus, we will summarize them here in words. They are:

Maxwell's equations

Changing \vec{E}

 $produces$ \vec{B}

- (1) a generalized form of Coulomb's law known as Gauss's law (Section 16–10) that relates electric field to its source, electric charge;
- (2) a similar law for the magnetic field, except that magnetic field lines are always continuous—they do not begin or end (as electric field lines do, on charges);
- (3) an electric field is produced by a changing magnetic field (Faraday's law);
- (4) a magnetic field is produced by an electric current (Ampère's law), or by a changing electric field.

Law (3) is Faraday's law (see Chapter 21, especially Section 21-4). The first part of law (4), that a magnetic field is produced by an electric current, was discovered by Oersted, and the mathematical relation is given by Ampère's law (Section 20–8). But the second part of law (4) is an entirely new aspect predicted by Maxwell. Maxwell argued that if a changing magnetic field produces an electric field, as given by Faraday's law, then the reverse might be true as well: a changing electric field will produce a magnetic field. This was an hypothesis by Maxwell, based on the idea of symmetry in nature. Indeed, the size of the effect in most cases is so small that Maxwell recognized it would be difficult to detect it experimentally.

* Maxwell's Fourth Equation (Ampère's Law Extended)

To back up the idea that a changing electric field might produce a magnetic field, we use an indirect argument that goes something like this. According to Ampère's law (Section 20-8), $\Sigma B_{\parallel} \Delta l = \mu_0 I$. That is, divide any closed path you choose into short segments Δl , multiply each segment by the parallel component of the magnetic field B at that segment, and then sum all these products over the complete closed path. That sum will then equal μ_0 times the total current I that passes through a surface bounded by the path. When we applied Ampère's law to the field around a straight wire (Section 20-8), we imagined the current as passing through the circular area enclosed by our circular loop. That area is the flat surface 1 shown in Fig. $22-2$. However, we could just as well use the sack-shaped surface 2 in Fig. 22-2 as the surface for Ampère's law because the same current I passes through it.

Now consider the closed path for the situation of Fig. 22–3, where a capacitor is being discharged. Ampère's law works for surface 1 (current I passes through surface 1), but it does not work for surface 2 because no current passes through surface 2. There is a magnetic field around the wire, so the left side of Ampère's law is not zero around the circular closed path; yet no current flows through surface 2, so the right side is zero for surface 2. We seem to have a contradiction of Ampère's law. There is a magnetic field present in Fig. 22–3. however, only if charge is flowing to or away from the capacitor plates. The changing charge on the plates means that the electric field between the plates is changing in time. Maxwell resolved the problem of no current through surface 2 in Fig. 22–3 by proposing that the changing electric field between the plates is *equivalent to* an electric current. He called it a **displacement current**, I_D . An ordinary current I is then called a "conduction current," and Ampère's law, as generalized by Maxwell, becomes

$$
\Sigma B_{\parallel} \Delta l = \mu_0 (I + I_{\rm D}).
$$

Ampère's law will now apply also for surface 2 in Fig. 22–3, where I_D refers to the changing electric field.

By combining Eq. 17-7 for the charge on a capacitor, $Q = CV$, with Eq. 17-4a, $V = Ed$, and Eq. 17-8, $C = \epsilon_0 A/d$, we can write $Q = CV = (\epsilon_0 A/d)(Ed) = \epsilon_0 AE$. Then the current I_D becomes

$$
I_{\rm D} = \frac{\Delta Q}{\Delta t} = \epsilon_0 \frac{\Delta \Phi_E}{\Delta t},
$$

where $\Phi_E = EA$ is the **electric flux**, defined in analogy to magnetic flux (Section 21-2). Then, Ampère's law becomes

$$
\Sigma B_{\parallel} \Delta l = \mu_0 I + \mu_0 \epsilon_0 \frac{\Delta \Phi_E}{\Delta t}.
$$
 (22-1)

This equation embodies Maxwell's idea that a magnetic field can be caused not only by a normal electric current, but also by a changing electric field or changing electric flux.

2 Production of Electromagnetic Waves

According to Maxwell, a magnetic field will be produced in empty space if there is a changing electric field. From this, Maxwell derived another startling conclusion. If a changing magnetic field produces an electric field, that electric field is itself changing. This changing electric field will, in turn, produce a magnetic field, which will be changing, and so it too will produce a changing electric field; and so on. When Maxwell worked with his equations, he found that the net result of these interacting changing fields was a *wave* of electric and magnetic fields that can propagate (travel) through space! We now examine, in a simplified way, how such electromagnetic waves can be produced.

Consider two conducting rods that will serve as an "antenna" (Fig. 22–4a). Suppose that these two rods are connected by a switch to the opposite terminals of a battery. As soon as the switch is closed, the upper rod quickly becomes positively charged and the lower one negatively charged. Electric field lines are formed as indicated by the lines in Fig. 22-4b. While the charges are flowing, a current exists whose direction is indicated by the black arrows. A magnetic field is therefore produced near the antenna. The magnetic field lines encircle the rod-like antenna and therefore, in Fig. 22–4, \vec{B} points into the page (\otimes) on the right and out of the page (\odot) on the left. Now we ask, how far out do these electric and magnetic fields extend? In the static case, the fields extend outward indefinitely far. However, when the switch in Fig. 22–4 is closed, the fields quickly appear nearby, but it takes time for them to reach distant points. Both electric and magnetic fields store energy, and this energy cannot be transferred to distant points at infinite speed.

FIGURE 22-3 A capacitor discharging. No conduction current passes through surface 2. An extra term is needed in Ampère's law.

FIGURE 22-4 Fields produced by charge flowing into conductors. It takes time for the \vec{E} and \vec{B} fields to travel outward to distant points. The fields are shown to the right of the antenna, but they move out in all directions, symmetrically about

the (vertical) antenna.

Ampère's law (generalized)

FIGURE 22-5 Sequence showing electric and magnetic fields that spread outward from oscillating charges on two conductors (the antenna) connected to an ac source (see the text).

Now we look at the situation of Fig. 22–5, where our antenna is connected to an ac generator. In Fig. 22-5a, the connection has just been completed. Charge starts building up, and fields form just as in Fig. 22–4b. The $+$ and $-$ signs in Fig. 22–5a indicate the net charge on each rod. The black arrows indicate the direction of the current. The electric field is represented by red lines in the plane of the page; and the magnetic field, according to the right-hand rule, is into (\otimes) or out of (\odot) the page. In Fig. 22–5b, the voltage of the ac generator has reversed in direction; the current is reversed and the new magnetic field is in the opposite direction. Because the new fields have changed direction, the old lines fold back to connect up to some of the new lines and form closed loops as shown.[†] The old fields, however, don't suddenly disappear; they are on their way to distant points. Indeed, because a changing magnetic field produces an electric field, and a changing electric field produces a magnetic field, this combination of changing electric and magnetic fields moving outward is self-supporting, no longer depending on the antenna charges.

The fields not far from the antenna, referred to as the *near field*, become quite complicated, but we are not so interested in them. We are mainly interested in the fields far from the antenna (they are generally what we detect). which we refer to as the radiation field. The electric field lines form loops, as shown in Fig. 22–6, and continue moving outward. The magnetic field lines also form closed loops, but are not shown since they are perpendicular to the page. Although the lines are shown only on the right of the source, fields also travel in other directions. The field strengths are greatest in directions perpendicular to the oscillating charges; and they drop to zero along the direction of oscillation above and below the antenna in Fig. 22-6.

FIGURE 22-6 (a) The radiation fields (far from the antenna) produced by a sinusoidal signal on the antenna. The red closed loops represent electric field lines. The magnetic field lines, perpendicular to the page and represented by blue \otimes and \odot , also form closed loops. (b) Very far from the antenna, the wave fronts (field lines) are essentially flat over a fairly large area, and are referred to as *plane waves*.

The magnitudes of both \vec{E} and \vec{B} in the radiation field are found to decrease with distance as $1/r$. (Compare this to the static electric field given by Coulomb's law where \vec{E} decreases as $1/r^2$.) The energy carried by the electromagnetic wave is proportional (as for any wave, Chapter 11) to the square of the amplitude, E^2 or B^2 , as will be discussed further in Section 22–7, so the intensity of the wave decreases as $1/r^2$.

 $\vec{E} \perp \vec{B} \perp \vec{v}$ in EM wave

Several things about the radiation field can be noted from Fig. 22–6. First, the electric and magnetic fields at any point are perpendicular to each other, and to the direction of wave travel. Second, we can see that the fields alternate in direction (\vec{B}) is into the page at some points and out of the page at others; \vec{E} points up at some points and down at others). Thus, the field strengths vary from a maximum in one direction, to zero, to a maximum in the other direction. The electric and magnetic fields are "in phase": that is, they each are zero at the same points and reach their maxima at the same points in space. Finally, very far from the antenna (Fig. 22–6b) the field lines are quite flat over a reasonably large area, and the waves are referred to as plane waves.

[†]We are considering waves traveling through empty space. There are no charges for lines of \vec{E} to start or stop on, so they form closed loops. Magnetic field lines always form closed loops.

If the source voltage varies sinusoidally, then the electric and magnetic field strengths in the radiation field will also vary sinusoidally. The sinusoidal character of the waves is shown in Fig. 22-7, which displays the field *strengths* as a function of position along the direction of wave travel. Notice that \vec{B} and \vec{E} are perpendicular to each other and to the direction of wave travel.

We call these waves electromagnetic (EM) waves. They are *transverse* waves because the amplitude is perpendicular to the direction of wave travel. However, EM waves are always waves of *fields*, not of matter (like waves on water or a rope). Because they are fields, EM waves can propagate in empty space.

As we have seen, EM waves are produced by electric charges that are oscillating, and hence are undergoing acceleration. In fact, we can say in general that

accelerating electric charges give rise to electromagnetic waves.

Maxwell derived a formula for the speed of EM waves:

 \overline{r}

$$
b = c = \frac{E}{B}, \qquad (22-2)
$$

where c is the special symbol for the speed of electromagnetic waves in empty space, and E and B are the magnitudes of electric and magnetic fields at the same point in space. More specifically, it was easily shown also that

$$
c = \frac{1}{\sqrt{\epsilon_0 \mu_0}}.\tag{22-3}
$$

When Maxwell put in the values for ϵ_0 and μ_0 , he found

$$
c = \frac{1}{\sqrt{\epsilon_0 \mu_0}} = \frac{1}{\sqrt{(8.85 \times 10^{-12} \text{ C}^2/\text{N} \cdot \text{m}^2)(4\pi \times 10^{-7} \text{N} \cdot \text{s}^2/\text{C}^2)}}
$$

= 3.00 × 10⁸ m/s,

which is equal to the measured speed of light in vacuum.

22-3 Light as an Electromagnetic Wave and the **Electromagnetic Spectrum**

Maxwell's prediction that EM waves should exist was startling. Equally remarkable was the speed at which EM waves were predicted to travel— 3.00×10^8 m/s, the same as the measured speed of light.

Light had been shown some 60 years before Maxwell's work to behave like a wave (we'll discuss this in Chapter 24). But nobody knew what kind of wave it was. What is it that is oscillating in a light wave? Maxwell, on the basis of the calculated speed of EM waves, argued that light must be an electromagnetic wave. This idea soon came to be generally accepted by scientists, but not fully until after EM waves were experimentally detected. EM waves were first generated and detected experimentally by Heinrich Hertz (1857-1894) in 1887, eight years after Maxwell's death. Hertz used a spark-gap apparatus in which charge was made to rush back and forth for a short time, generating waves whose

FIGURE 22-7 Electric and magnetic field strengths in an electromagnetic wave. \vec{E} and \vec{B} are at right angles to each other. The entire pattern moves in a direction perpendicular to both \vec{E} and \vec{B} .

EM waves are produced by accelerating electric charges

c is symbol for speed of light

$$
2-3)
$$
 Speed of EM waves

SECTION 22-3 Light as an Electromagnetic Wave and the Electromagnetic Spectrum 619

frequency was about 10^9 Hz. He detected them some distance away using a loop of wire in which an emf was produced when a changing magnetic field passed through. These waves were later shown to travel at the speed of light, 3.00×10^8 m/s, and to exhibit all the characteristics of light such as reflection, refraction, and interference. The only difference was that they were not visible. Hertz's experiment was a strong confirmation of Maxwell's theory.

The wavelengths of visible light were measured in the first decade of the nineteenth century, long before anyone imagined that light was an electromagnetic wave. The wavelengths were found to lie between 4.0×10^{-7} m and 7.5×10^{-7} m; or 400 nm to 750 nm (1 nm = 10^{-9} m). The frequencies of visible light can be found using Eq. $11-12$, which we rewrite here:

Wavelength and frequency related to speed

$$
c = \lambda f, \tag{22-4}
$$

where f and λ are the frequency and wavelength, respectively, of the wave. Here, c is the speed of light, 3.00×10^8 m/s; it gets the special symbol c because of its universality for all EM waves in free space. Equation 22–4 tells us that the frequencies of visible light are between 4.0×10^{14} Hz and 7.5×10^{14} Hz. (Recall that $1 Hz = 1$ cycle per second = $1 s^{-1}$.)

But visible light is only one kind of EM wave. As we have seen, Hertz produced EM waves of much lower frequency, about 10^9 Hz. These are now called radio waves, since frequencies in this range are used to transmit radio and TV signals. Electromagnetic waves, or EM radiation as we sometimes call it, have been produced or detected over a wide range of frequencies. They are usually categorized as shown in Fig. 22–8, which is known as the **electromagnetic spectrum**.

EM spectrum

Radio waves and microwaves can be produced in the laboratory using electronic equipment (Fig. 22–5). Higher-frequency waves are very difficult to produce electronically. These and other types of EM waves are produced in natural processes, as emission from atoms, molecules, and nuclei (more on this later). EM waves can be produced by the acceleration of electrons or other charged particles, such as electrons accelerating in the antenna of Fig. 22-5. Another example is X-rays, which are produced (Chapters 25 and 28) when fast-moving electrons are rapidly decelerated upon striking a metal target. Even the visible light emitted by an ordinary incandescent bulb is due to electrons undergoing acceleration within the hot filament.

We will meet various types of EM waves later. However, it is worth mentioning here that infrared (IR) radiation (EM waves whose frequency is just less than that of visible light) is mainly responsible for the heating effect of the Sun. The Sun emits not only visible light but substantial amounts of IR and UV (ultraviolet) as well. The molecules of our skin tend to "resonate" at infrared frequencies, so it is these that are preferentially absorbed and thus warm us. We humans experience EM waves differently depending on their wavelengths: Our eyes detect wavelengths between about 4×10^{-7} m and 7.5×10^{-7} m (visible light), whereas our skin detects longer wavelengths (IR). Many EM wavelengths we don't detect directly at all.

Light and other electromagnetic waves travel at a speed of 3×10^8 m/s. Compare this to sound, which travels (see Chapter 12) at a speed of about 300 m/s in air, a million times slower; or to typical freeway speeds of a car, 30 m/s (100 km/h, or 60 mi/h), 10 million times slower than light. EM waves differ from sound waves in another big way: sound waves travel in a medium such as air, and involve motion of air molecules; EM waves do not involve any material—only fields, and they can travel in empty space.

EXAMPLE 22-1 Wavelengths of EM waves. Calculate the wavelength (a) of a 60-Hz EM wave, (b) of a 93.3-MHz FM radio wave, and (c) of a beam of visible red light from a laser at frequency 4.74×10^{14} Hz.

APPROACH All of these waves are electromagnetic waves, so their speed is $c = 3.00 \times 10^8$ m/s. We solve for λ in Eq. 22–4: $\lambda = c/f$. SOLUTION (a)

$$
\lambda = \frac{c}{f} = \frac{3.00 \times 10^8 \,\mathrm{m/s}}{60 \,\mathrm{s}^{-1}} = 5.0 \times 10^6 \,\mathrm{m},
$$

or 5000 km. 60 Hz is the frequency of ac current in the United States, and, as we see here, one wavelength stretches all the way across the continental USA. (b)

$$
\lambda = \frac{3.00 \times 10^8 \,\mathrm{m/s}}{93.3 \times 10^6 \,\mathrm{s}^{-1}} = 3.22 \,\mathrm{m}.
$$

The length of an FM antenna is about half this $(\frac{1}{2}\lambda)$, or $1\frac{1}{2}$ m. (c)

$$
\lambda = \frac{3.00 \times 10^8 \,\mathrm{m/s}}{4.74 \times 10^{14} \,\mathrm{s}^{-1}} = 6.33 \times 10^{-7} \,\mathrm{m} \; (= 633 \,\mathrm{nm}).
$$

EXERCISE A What are the frequencies of (a) an 80-m-wavelength radio wave, and (b) an X-ray of wavelength 5.5×10^{-11} m?

EXAMPLE 22-2 ESTIMATE Cell phone antenna. The antenna of a cell phone is often $\frac{1}{4}$ wavelength long. A particular cell phone has an 8.5-cm-long straight rod for its antenna. Estimate the operating frequency of this phone.

APPROACH The basic equation relating wave speed, wavelength, and frequency is $c = \lambda f$; the wavelength λ equals four times the antenna's length.

SOLUTION The antenna is $\frac{1}{4}\lambda$ long, so $\lambda = 4(8.5 \text{ cm}) = 34 \text{ cm} = 0.34 \text{ m}$. Then $f = c/\lambda = (3.0 \times 10^8 \text{ m/s})/(0.34 \text{ m}) = 8.8 \times 10^8 \text{ Hz} = 880 \text{ MHz}.$

NOTE Radio antennas are not always straight conductors. The conductor may be a round loop to save space. See Fig. 22-17b.

EXERCISE B How long should a $\frac{1}{4}$ - λ antenna be for an aircraft radio operating at 165 MHz?

Electromagnetic waves can travel along transmission lines as well as in empty space. When a source of emf is connected to a transmission line—be it two parallel wires or a coaxial cable (Fig. $22-9$)—the electric field within the wire is not set up immediately at all points along the wires. This is based on the same argument we used in Section 22–2 with reference to Fig. 22–5. Indeed, it can be shown that if the wires are separated by empty space or air, the electrical signal travels along the wires at the speed $c = 3.0 \times 10^8$ m/s. For example, when you flip a light switch, the light actually goes on a tiny fraction of a second later. If the wires are in a medium whose electric permittivity is ϵ and magnetic permeability is μ (Sections $17-8$ and $20-12$, respectively), the speed is not given by Eq. 22–3, but by

$$
v=\frac{1}{\sqrt{\epsilon\mu}}\cdot
$$

SECTION 22-3 Light as an Electromagnetic Wave and the Electromagnetic Spectrum 621

EXAMPLE 22-3 ESTIMATE Voice speed through the wires. When you speak on the telephone from Los Angeles to a friend in New York some 4000 km away, how long does it take the signal carrying your voice to travel that distance?

APPROACH The signal is carried on a telephone wire or in the air via satellite. In either case it is an electromagnetic wave. Electronics as well as the wire or cable slow things down, but as a rough estimate we take the speed to be $c = 3.0 \times 10^8 \,\mathrm{m/s}$.

SOLUTION Since speed = distance/time, then time = distance/speed = $(4.0 \times 10^6 \text{ m})/(3.0 \times 10^8 \text{ m/s}) = 1.3 \times 10^{-2} \text{ s}$, or about $\frac{1}{100}$ s.

NOTE Such a small amount of time normally goes unnoticed.

EXERCISE C If your voice traveled as a sound wave, how long would it take in Example 22-3?

22-4 Measuring the Speed of Light

Galileo attempted to measure the speed of light by trying to measure the time required for light to travel a known distance between two hilltops. He stationed an assistant on one hilltop and himself on another, and ordered the assistant to lift the cover from a lamp the instant he saw a flash from Galileo's lamp. Galileo measured the time between the flash of his lamp and when he received the light from his assistant's lamp. The time was so short that Galileo concluded it merely represented human reaction time, and that the speed of light must be extremely high.

The first successful determination that the speed of light is finite was made by the Danish astronomer Ole Roemer (1644-1710). Roemer had noted that the carefully measured orbital period of Io, a moon of Jupiter with an average period of 42.5 h, varied slightly, depending on the relative motion of Earth and Jupiter. When Earth was moving away from Jupiter, the period of Io was slightly longer, and when Earth was moving toward Jupiter, the period was slightly shorter. He attributed this variation in the apparent period to the change in distance between the Earth and Jupiter during one of Io's periods, and the time it took light to travel this distance. Roemer concluded that the speed of light though great—is finite.

Since then a number of techniques have been used to measure the speed of light. Among the most important were those carried out by the American Albert A. Michelson (1852–1931). Michelson used the rotating mirror apparatus diagrammed in Fig. 22-10 for a series of high-precision experiments carried out from 1880 to the 1920s. Light from a source was directed at one face of a rotating eight-sided mirror. The reflected light traveled to a stationary mirror a large distance away and back again as shown. If the rotating mirror

Michelson measures c
was turning at just the right rate, the returning beam of light would reflect from one face of the mirror into a small telescope through which the observer looked. If the speed of rotation was only slightly different, the beam would be deflected to one side and would not be seen by the observer. From the required speed of the rotating mirror and the known distance to the stationary mirror, the speed of light could be calculated. In the 1920s, Michelson set up the rotating mirror on the top of Mt. Wilson in southern California and the stationary mirror on Mt. Baldy (Mt. San Antonio) 35 km away. He later measured the speed of light in vacuum using a long evacuated tube.

Today the speed of light, c , in vacuum is taken as

$$
c = 2.99792458 \times 10^8
$$
 m/s.

and is defined to be this value. This means that the standard for length, the meter, is no longer defined separately. Instead, as we noted in Section 1-5, the meter is now formally defined as the distance light travels in vacuum in 1/299,792,458 of a second.

We usually round off c to

$$
c = 3.00 \times 10^8 \,\mathrm{m/s}
$$

when extremely precise results are not required. In air, the speed is only slightly less.

5 Energy in EM Waves

Electromagnetic waves carry energy from one region of space to another. This energy is associated with the moving electric and magnetic fields. In Section 17–9, we saw that the energy density $u_E (J/m^3)$ stored in an electric field E is $u_E = \frac{1}{2} \epsilon_0 E^2$ (Eq. 17–11). The energy density stored in a magnetic field B, as we discussed in Section 21-10, is given by $u_B = \frac{1}{2}B^2/\mu_0$ (Eq. 21-10). Thus, the total energy stored per unit volume in a region of space where there is an electromagnetic wave is

$$
u = u_E + u_B = \frac{1}{2} \epsilon_0 E^2 + \frac{1}{2} \frac{B^2}{\mu_0}.
$$
 (22-5)

In this equation, E and B represent the electric and magnetic field strengths of the wave at any instant in a small region of space. We can write Eq. 22-5 in terms of the E field only using Eqs. 22–2 ($B = E/c$) and 22–3 ($c = 1/\sqrt{\epsilon_0 \mu_0}$) to obtain

$$
u = \frac{1}{2} \epsilon_0 E^2 + \frac{1}{2} \frac{\epsilon_0 \mu_0 E^2}{\mu_0} = \epsilon_0 E^2.
$$
 (22-6a)

Note here that the energy density associated with the B field equals that due to the E field, and each contributes half to the total energy. We can also write the energy density in terms of the B field only:

$$
u = \epsilon_0 E^2 = \epsilon_0 c^2 B^2 = \frac{B^2}{\mu_0},
$$
 (22-6b)

or in one term containing both E and B ,

$$
u = \epsilon_0 E^2 = \epsilon_0 E c B = \frac{\epsilon_0 E B}{\sqrt{\epsilon_0 \mu_0}} = \sqrt{\frac{\epsilon_0}{\mu_0}} E B.
$$
 (22-6c)

The energy a wave transports per unit time per unit area is the **intensity** I, as defined in Sections 11–9 and 12–2.[†] The units of I are W/m². The energy passing through an area A in a time Δt (see Fig. 22-11) is

$$
\Delta U = u \Delta V = (u)(A \Delta x) = (\epsilon_0 E^2)(Ac \Delta t)
$$

because $\Delta x = c \Delta t$. Therefore, the magnitude of the intensity (energy per unit area per time Δt , or power per unit area) is

$$
I = \frac{\Delta U}{A \Delta t} = \frac{(\epsilon_0 E^2)(Ac \Delta t)}{A \Delta t} = \epsilon_0 c E^2.
$$

From Eqs. 22–2 and 22–3, this can also be written

Intensity of EM waves

$$
I = \epsilon_0 c E^2 = \frac{c}{\mu_0} B^2 = \frac{EB}{\mu_0}.
$$
 (22-7)

The average intensity over an extended period of time, if E and B are sinusoidal so that $\overline{E^2} = E_0^2/2$ (just as for electric currents and voltages, Section 18–7), is

Average intensity

$$
\overline{I} = \frac{1}{2} \epsilon_0 c E_0^2 = \frac{1}{2} \frac{c}{\mu_0} B_0^2 = \frac{E_0 B_0}{2\mu_0}.
$$
 (22-8)

Here E_0 and B_0 are the maximum values of E and B. We can also write

$$
\overline{I} = \frac{E_{\rm rms} B_{\rm rms}}{\mu_0},
$$

where E_{rms} and B_{rms} are the rms values $(E_{\text{rms}} = \sqrt{\overline{E^2}}$, $B_{\text{rms}} = \sqrt{\overline{B^2}}$).

EXAMPLE 22-4 E and B from the Sun. Radiation from the Sun reaches the Earth (above the atmosphere) at a rate of about $1350 \text{ J/s} \cdot \text{m}^2$ (1.1350 W/m^2) . Assume that this is a single EM wave, and calculate the maximum values of E and B .

APPROACH We are given the intensity $\overline{I} = 1350 \text{ J/s} \cdot \text{m}^2$. We solve Eq. 22-8 $(\overline{I} = \frac{1}{2} \epsilon_0 c E_0^2)$ for E_0 in terms of \overline{I} .

SOLUTION
$$
E_0 = \sqrt{\frac{2\overline{I}}{\epsilon_0 c}} = \sqrt{\frac{2(1350 \text{ J/s} \cdot \text{m}^2)}{(8.85 \times 10^{-12} \text{ C}^2/\text{N} \cdot \text{m}^2)(3.00 \times 10^8 \text{ m/s})}}
$$

= 1.01 × 10³ V/m.

From Eq. 22–2, $B = E/c$, so

$$
B_0 = \frac{E_0}{c} = \frac{1.01 \times 10^3 \,\text{V/m}}{3.00 \times 10^8 \,\text{m/s}} = 3.37 \times 10^{-6} \,\text{T}.
$$

NOTE Although B has a small numerical value compared to E (because of the way the different units for E and B are defined), B contributes the same energy to the wave as E does, as we saw earlier.

[†]The intensity I for EM waves is often called the **Poynting vector** and given the symbol S. Its direction is that in which the energy is being transported, which is the direction the wave is traveling, and its magnitude is the intensity $(S = I)$.

22-6 Momentum Transfer and Radiation Pressure

If electromagnetic waves carry energy, then we might expect them to also carry linear momentum. When an electromagnetic wave encounters the surface of an object and is absorbed or reflected, a force will be exerted on the surface as a result of the momentum transfer $(F = \Delta p/\Delta t)$ just as when a moving object strikes a surface. The force per unit area exerted by the waves is called **radiation** pressure, and its existence was predicted by Maxwell. He showed that if a beam of EM radiation (light, for example) is completely absorbed by an object, then the momentum transferred is

> $\Delta p = \frac{\Delta U}{c},$ radiation $(22-9a)$ absorbed

where ΔU is the energy absorbed by the object in a time Δt and c is the speed of light. If, instead, the radiation is fully reflected (suppose the object is a mirror), then the momentum transferred is twice as great, just as when a ball bounces elastically off a surface:

$$
\Delta p = \frac{2\Delta U}{c}.
$$
 [radiation] (22–9b)

If a surface absorbs some of the energy, and reflects some of it, then $\Delta p = a \Delta U/c$, where a has a value between 1 and 2.

Using Newton's second law we can calculate the force and the pressure exerted by EM radiation on an object. The force F is given by

$$
F = \frac{\Delta p}{\Delta t}.
$$

The radiation pressure P (assuming full absorption) is given by (see Eq. 22–9a)

$$
P = \frac{F}{A} = \frac{1}{A} \frac{\Delta p}{\Delta t} = \frac{1}{Ac} \frac{\Delta U}{\Delta t}.
$$

We discussed in Section 22–5 that the average intensity \bar{I} is defined as energy per unit time per unit area:

$$
\overline{I} = \frac{\Delta U}{A \, \Delta t} \cdot
$$

Hence the radiation pressure is

$$
P = \frac{\overline{I}}{c}.
$$
 (22-10a)

If the light is fully reflected, the pressure is twice as great $(Eq. 22-9b)$:

$$
P=\frac{2\overline{I}}{c}.
$$

EXAMPLE 22-5 ESTIMATE Solar pressure. Radiation from the Sun that reaches the Earth's surface (after passing through the atmosphere) transports energy at a rate of about $1000 \,\mathrm{W/m^2}$. Estimate the pressure and force exerted by the Sun on your outstretched hand.

APPROACH The radiation is partially reflected and partially absorbed, so let us estimate simply $P = \overline{I}/c$.

SOLUTION
$$
P \approx \frac{I}{c} = \frac{1000 \text{ W/m}^2}{3 \times 10^8 \text{ m/s}} \approx 3 \times 10^{-6} \text{ N/m}^2
$$
.

An estimate of the area of your outstretched hand might be about 10 cm by 20 cm, so $A = 0.02$ m². Then the force is

$$
F = PA \approx (3 \times 10^{-6} \,\text{N/m}^2)(0.02 \,\text{m}^2) \approx 6 \times 10^{-8} \,\text{N}.
$$

NOTE These numbers are tiny. The force of gravity on your hand, for comparison, is maybe a half pound, or with $m = 0.2$ kg, $mg \approx (0.2 \text{ kg})(9.8 \text{ m/s}^2) \approx 2 \text{ N}$. The radiation pressure on your hand is imperceptible compared to gravity.

Radiation pressure (reflected)

Radiation pressure (absorbed)

 $(22-10b)$

 \overline{X} PHYSICS

APPLIED "Wireless" transmission

Transmission

Carrier frequency

of radio waves

Although you cannot directly feel the effects of radiation pressure, the phenomenon is quite dramatic when applied to atoms irradiated by a finely focused laser beam. An atom has a mass on the order of 10^{-27} kg, and a laser beam can deliver energy at a rate of 1000 W/m^2 . This is the same intensity used in Example 22–5, above, but here a radiation pressure of 10^{-6} N/m² would be very significant on a molecule whose mass might be 10^{-23} to 10^{-26} kg. It is possible to move atoms and molecules around by steering them with a laser beam, in a device called "optical tweezers." Optical tweezers have some remarkable applications. They are of great interest to biologists, especially since optical tweezers can manipulate live microorganisms, and components within a cell, without damaging them. Optical tweezers have been used to measure the elastic properties of DNA by pulling each end of the molecule with such a laser "tweezers."

22-7 Radio and Television; **Wireless Communication**

Electromagnetic waves offer the possibility of transmitting information over long distances. Among the first to realize this and put it into practice was Guglielmo Marconi (1874–1937) who, in the 1890s, invented the radio and developed the wireless telegraph. With it, messages could be sent at the speed of light without the use of wires. The first signals were merely long and short pulses that could be translated into words by a code, such as the "dots" and "dashes" of the Morse code: they were digital wireless, believe it or not. In 1895 Marconi sent wireless signals a kilometer or two. By 1901 he had sent test signals 3000 km across the ocean from Newfoundland, Canada, to Cornwall, England. In 1903 he sent the first practical commercial messages from Cape Cod, Massachusetts, to England: the London Times printed news items sent from its New York correspondent. 1903 was also the year of the first powered airplane flight by the Wright brothers. The hallmarks of the modern age—wireless communication and flight—date from the same year.

The next decade saw the development of vacuum tubes. Out of this early work radio and television were born. We now discuss briefly (1) how radio and TV signals are transmitted, and (2) how they are received at home.

The process by which a radio station transmits information (words and music) is outlined in Fig. 22-12. The audio (sound) information is changed into an electrical signal of the same frequencies by, say, a microphone or recording head. This electrical signal is called an audiofrequency (AF) signal, since the frequencies are in the audio range (20 to 20,000 Hz). The signal is amplified electronically and is then mixed with a radio-frequency (RF) signal called its carrier frequency, which represents that station. AM radio stations have carrier frequencies from about 530 kHz to 1700 kHz. For example, "710 on your dial" means a station whose carrier frequency is 710 kHz. FM radio stations have much higher carrier frequencies, between 88 MHz and 108 MHz. The carrier frequencies for broadcast TV stations in the United States lie between 54 MHz and 88 MHz. between 174 MHz and 216 MHz, and between 470 MHz and 890 MHz.

FIGURE 22-13 In amplitude modulation (AM) , the amplitude of the carrier signal is made to vary in proportion to the audio signal's amplitude.

The mixing of the audio and carrier frequencies is done in two ways. In amplitude modulation (AM), the amplitude of the high frequency carrier wave is made to vary in proportion to the amplitude of the audio signal, as shown in Fig. 22-13. It is called "amplitude modulation" because the *amplitude* of the carrier is altered ("modulate" means to change or alter). In frequency **modulation** (FM), the *frequency* of the carrier wave is made to change in proportion to the audio signal's amplitude, as shown in Fig. $22-14$. The mixed signal is amplified further and sent to the transmitting antenna, where the complex mixture of frequencies is sent out in the form of EM waves.

A television transmitter works in a similar way, using FM for audio and AM for video; both audio and video signals (see Section $17-10$) are mixed with carrier frequencies.

Now let us look at the other end of the process, the reception of radio and TV programs at home. A simple radio receiver is diagrammed in Fig. 22-15. The EM waves sent out by all stations are received by the antenna. The signal the antenna detects and sends to the receiver is very small and contains frequencies from many different stations. The receiver selects out a particular RF frequency (actually a narrow range of frequencies) corresponding to a particular station using a resonant LC circuit (Section 21–14). A simple way of tuning a station is shown in Fig. 22–16. A particular station is "tuned-in" by adjusting C and/or L so that the resonant frequency of the circuit equals that of the station's carrier frequency. The signal, containing both audio and carrier frequencies, next goes to the *demodulator*, or *detector* (Fig. 22-15), where "demodulation" takes place—that is, the RF carrier frequency is separated from the audio signal. The audio signal is amplified and sent to a loudspeaker or headphones.

Modern receivers have more stages than those shown. Various means are used to increase the sensitivity and selectivity (ability to detect weak signals and distinguish them from other stations), and to minimize distortion of the original signal.[†]

[†]For *FM stereo broadcasting*, two signals are carried by the carrier wave. One signal contains frequencies up to about 15 kHz, which includes most audio frequencies. The other signal includes the same range of frequencies, but 19 kHz is added to it. A stereo receiver subtracts this 19,000-Hz signal and distributes the two signals to the left and right channels. The first signal consists of the sum of left and right channels $(L + R)$, so mono radios detect all the sound. The second signal is the difference between left and right $(L - R)$. Hence the receiver must add and subtract the two signals to get pure left and right signal for each channel.

FIGURE 22-14 In frequency modulation (FM), the frequency of the carrier signal is made to change in proportion to the audio signal's amplitude. This method is used by FM radio and television.

> \overline{A} PHYSICS APPLIED AM and FM

FIGURE 22-15 Block diagram of a simple radio receiver.

 \overrightarrow{A} PHYSICS APPLIED Radio and TV receiver

Television

A television receiver does similar things to both the audio and the video signals. The audio signal goes finally to the loudspeaker, and the video signal to the monitor, such as a *cathode ray tube* (CRT) or LCD screen (Sections 17–10 and 24–11).

```
Antennas
```
One kind of antenna consists of one or more conducting rods; the electric field in the EM waves exerts a force on the electrons in the conductor, causing them to move back and forth at the frequencies of the waves (Fig. $22-17a$). A second type of antenna consists of a tubular coil of wire which detects the magnetic field of the wave: the changing B field induces an emf in the coil (Fig. $22-17b$). A satellite dish (Fig. 22–18) consists of a parabolic reflector that focuses the EM waves onto a "horn," similar to a concave mirror telescope (Fig. 25–21).

FIGURE 22-17 Antennas. (a) Electric field of EM wave produces a current in an antenna consisting of straight wire or rods. (b) Changing magnetic field induces an emf and current in a loop antenna.

FIGURE 22-18 A satellite dish.

EXAMPLE 22-6 Tuning a station. Calculate the transmitting wavelength of an FM radio station that transmits at 100 MHz.

APPROACH Radio is transmitted as an EM wave, so the speed is $c = 3.0 \times 10^8$ m/s. The wavelength is found from Eq. 22–4, $\lambda = c/f$. **SOLUTION** The carrier frequency is $f = 100 \text{ MHz} = 1.0 \times 10^8 \text{ s}^{-1}$, so

$$
\lambda = \frac{c}{f} = \frac{(3.0 \times 10^8 \,\mathrm{m/s})}{(1.0 \times 10^8 \,\mathrm{s}^{-1})} = 3.0 \,\mathrm{m}.
$$

NOTE The wavelengths of other FM signals (88 MHz to 108 MHz) are close to the 3.0-m wavelength of this station. FM antennas are typically 1.5 m long, or about a half wavelength. This length is chosen so that the antenna reacts in a resonant fashion and thus is more sensitive to FM frequencies. AM radio antennas would have to be much too long to be either $\frac{1}{2}\lambda$ or $\frac{1}{4}\lambda$.

Other EM Wave Communications

The various regions of the radio-wave spectrum are assigned by governmental agencies for various purposes. Besides those mentioned above, there are "bands" assigned for use by ships, airplanes, police, military, amateurs, satellites and space, and radar. Cell phones, for example, are complete radio transmitters and receivers which in the U.S. function on two different bands: 800 MHz and 1900 MHz $(=1.9 \text{ GHz})$, whereas in Europe and Asia 900-MHz and 1800-MHz bands are used in the international standard called GSM (Global System for Mobile Communication). Radio-controlled toys (cars, sailboats, robotic animals, etc.) can use various frequencies from 27 MHz to 75 MHz. Automobile remote (keyless) entry may operate around 300 MHz or 400 MHz.

Cable TV channels are carried as electromagnetic waves along a coaxial cable (see Fig. 22–9) rather than being broadcast and received through the "air." The channels are in the same part of the EM spectrum, hundreds of MHz, but some are at frequencies not available for TV broadcast. Digital satellite TV and radio are carried in the microwave portion of the spectrum (12 to 14 GHz and 2.3 GHz, respectively).

Summary

James Clerk Maxwell synthesized an elegant theory in which all electric and magnetic phenomena could be described using four equations, now called Maxwell's equations. They are based on earlier ideas, but Maxwell added one more-that a changing electric field produces a magnetic field.

Maxwell's theory predicted that transverse electromagnetic (EM) waves would be produced by accelerating electric charges, and these waves would propagate (move) through space at the speed of light, given by the formula

$$
c = \frac{1}{\sqrt{\epsilon_0 \mu_0}}.\tag{22-3}
$$

The oscillating electric and magnetic fields in an EM wave are perpendicular to each other and to the direction of propagation. These waves are waves of fields, not matter, and can propagate in empty space.

Questions

- 1. The electric field in an EM wave traveling north oscillates in an east-west plane. Describe the direction of the magnetic field vector in this wave.
- 2. Is sound an electromagnetic wave? If not, what kind of wave is it?
- 3. Can EM waves travel through a perfect vacuum? Can sound waves?
- 4. When you flip a light switch on, does the light go on immediately? Explain.
- 5. Are the wavelengths of radio and television signals longer or shorter than those detectable by the human eye?
- 6. When you connect two loudspeakers to the output of a stereo amplifier, should you be sure the lead-in wires are equal in length so that there will not be a time lag between speakers? Explain.
- 7. In the electromagnetic spectrum, what type of EM wave would have a wavelength of 10^3 km? 1 km? 1 m? 1 cm? $1mm?1~\mu m?$

Problems

22-1 Changing \vec{E} Produces \vec{B}

- *1. (II) At a given instant, a 1.8-A current flows in the wires connected to a parallel-plate capacitor. What is the rate at which the electric field is changing between the plates if the square plates are 1.60 cm on a side?
- *2. (II) A 1200-nF capacitor with circular parallel plates 2.0 cm in diameter is accumulating charge at the rate of $35.0 \,\mathrm{mC/s}$ at some instant in time. What will be the magnitude of the induced magnetic field 10.0 cm radially outward from the center of the plates? What will be the magnitude of the field after the capacitor is fully charged?

22-2 EM Waves

3. (I) If the magnetic field in a traveling EM wave has a peak magnitude of 17.5 nT at a given point, what is the peak magnitude of the electric field?

The wavelength λ and frequency f of EM waves are related to their speed c by

$$
c = \lambda f, \tag{22-4}
$$

just as for other waves.

After EM waves were experimentally detected, the idea that light is an EM wave (of very high frequency) became generally accepted. The electromagnetic spectrum includes EM waves of a wide variety of wavelengths, from microwaves and radio waves to visible light to X-rays and gamma rays, all of which travel through space at a speed $c = 3.0 \times 10^8$ m/s.

[*The average *intensity* (W/m^2) of an EM wave is

$$
\overline{I} = \frac{1}{2} \epsilon_0 c E_0^2 = \frac{1}{2} \frac{c}{\mu_0} B_0^2 = \frac{1}{2} \frac{E_0 B_0}{\mu_0}, \qquad (22-8)
$$

where E_0 and B_0 are the peak values of the electric and magnetic fields, respectively, in the wave.]

^{[*}EM waves carry momentum and exert a *radiation pressure* proportional to the intensity I of the wave.]

- 8. Can radio waves have the same frequencies as sound waves (20 Hz-20,000 Hz)?
- *9. Can two radio or TV stations broadcast on the same carrier frequency? Explain.
- * 10. If a radio transmitter has a vertical antenna, should a receiver's antenna (rod type) be vertical or horizontal to obtain best reception?
- *11. The carrier frequencies of FM broadcasts are much higher than for AM broadcasts. On the basis of what you learned about diffraction in Chapter 11, explain why AM signals can be detected more readily than FM signals behind low hills or buildings.
- * 12. Discuss how cordless telephones make use of EM waves. What about cell phones?
- *13. A lost person may signal by flashing a flashlight on and off using Morse code. This is actually a modulated EM wave. Is it AM or FM? What is the frequency of the carrier, approximately?
	- **4.** (I) In an EM wave traveling west, the B field oscillates vertically and has a frequency of 80.0 kHz and an rms strength of 6.75×10^{-9} T. What are the frequency and rms strength of the electric field, and what is its direction? [*Hint*: see Fig. 22-7.]

22-3 and 22-4 EM Spectrum and Speed

- 5. (I) What is the frequency of a microwave whose wavelength is 1.60 cm?
- 6. (I) What is the wavelength of a 29.75×10^{9} -Hz radar signal?
- 7. (I) An EM wave has frequency 9.66×10^{14} Hz. What is its wavelength, and how would we classify it?
- 8. (I) An EM wave has a wavelength of 650 nm. What is its frequency, and how would we classify it?
- 9. (I) How long does it take light to reach us from the Sun, 1.50×10^8 km away?
- 10. (I) A widely used "short-wave" radio broadcast band is referred to as the 49-m band. What is the frequency of a 49-m radio signal?
- $11.$ (II) Our nearest star (other than the Sun) is 4.2 light-years away. That is, it takes 4.2 years for the light it emits to reach Earth. How far away is it in meters?
- 12. (II) A light-year is a measure of distance (not time). How many meters does light travel in a year?
- 13. (II) How long would it take a message sent as radio waves from Earth to reach Mars (a) when nearest Earth, (b) when farthest from Earth? [Hint: see Table $5-2$, p. 125.]
- 14. (II) What is the minimum angular speed at which Michelson's eight-sided mirror would have had to rotate to reflect light into an observer's eye by succeeding mirror faces (Fig. 22-10)?
- 15. (II) A student wants to scale down Michelson's lightspeed experiment to a size that will fit in one room. A sixsided mirror is available, and the stationary mirror can be mounted 12 m from the rotating mirror. If the arrangement is otherwise as shown in Fig. 22-10, at what minimum rate must the mirror rotate?
- 16. (II) Who will hear the voice of a singer first—a person in the balcony 50.0 m away from the stage (Fig. 22-19), or a person 3000 km away at home whose ear is next to the radio? How much sooner? Assume that the microphone is a few centimeters from the singer and the temperature is 20° C.

17. (II) Pulsed lasers used in science and medicine produce very short bursts of electromagnetic energy. If the laser light wavelength is 1062 nm (this corresponds to a Neodymium-YAG laser), and the pulse lasts for 32 picoseconds, how many wavelengths are found within the laser pulse? How short would the pulse need to be to fit only one wavelength?

* 22-5 Energy in EM Waves

- * 18. (I) The E field in an EM wave in free space has a peak of $21.8 \,\mathrm{mV/m}$. What is the average rate at which this wave carries energy across unit area per unit time?
- *19. (II) The magnetic field in a traveling EM wave has an rms strength of 28.5 nT. How long does it take to deliver 235 J of energy to 1.00 cm^2 of a wall that it hits perpendicularly?
- $*$ 20. (II) How much energy is transported across a 1.00-cm² area per hour by an EM wave whose E field has an rms strength of 38.6 mV/m?
- *21. (II) A spherically spreading EM wave comes from a 1200-W source. At a distance of 10.0 m, what is the average intensity, and what is the rms value of the electric field?
- $*22$. (II) A 12.8-mW laser puts out a narrow beam 1.75 mm in diameter. What are the average (rms) values of E and B in the beam?
- * 23. (II) Estimate the average power output of the Sun, given that about $1350 \,\mathrm{W/m^2}$ reaches the upper atmosphere of the Earth.
- $*$ 24. (II) If the amplitude of the B field of an EM wave is 2.5×10^{-7} T, (*a*) what is the amplitude of the *E* field? (b) What is the average power per unit area of the EM wave?
- * 25. (II) A high-energy pulsed laser emits a 1.0-ns-long pulse of average power 2.8×10^{11} W. The beam is 2.2×10^{-3} m in radius. Determine (a) the energy delivered in each pulse, and (b) the rms value of the electric field.

* 22-6 Radiation Pressure

* 26. (II) Estimate the radiation pressure due to a 100-W bulb at a distance of 8.0 cm from the center of the bulb. Estimate the force exerted on your fingertip if you place it at this point.

* 22-7 Radio, TV

- $*$ 27. (I) What is the range of wavelengths for (a) FM radio $(88 \text{ MHz}$ to $108 \text{ MHz})$ and (b) AM radio $(535 \text{ kHz}$ to 1700 kHz)?
- * 28. (I) Estimate the wavelength for 1.9-GHz cell phone reception.
- * 29. (I) Compare 940 on the AM dial to 94 on the FM dial. Which has the longer wavelength, and by what factor is it larger?
- *30. (I) What are the wavelengths for two TV channels that broadcast at 54.0 MHz (Channel 2) and 806 MHz (Channel 69)?
- * 31. (I) The variable capacitor in the tuner of an AM radio has a capacitance of 2800 pF when the radio is tuned to a station at 550 kHz. What must the capacitance be for a station near the other end of the dial, 1610 kHz?
- * 32. (I) The oscillator of a 96.1-MHz FM station has an inductance of 1.8 μ H. What value must the capacitance be?
- *33. (II) A certain FM radio tuning circuit has a fixed capacitor $C = 840$ pF. Tuning is done by a variable inductance. What range of values must the inductance have to tune stations from 88 MHz to 108 MHz?
- *34. (II) An amateur radio operator wishes to build a receiver that can tune a range from 14.0 MHz to 15.0 MHz. A variable capacitor has a minimum capacitance of 82 pF. (a) What is the required value of the inductance? (b) What is the maximum capacitance used on the variable capacitor?
- *35. (II) A satellite beams microwave radiation with a power of 10 kW toward the Earth's surface, 550 km away. When the beam strikes Earth, its circular diameter is about 1500 m. Find the rms electric field strength of the beam.
- * 36. (III) A 1.60-m-long FM antenna is oriented parallel to the electric field of an EM wave. How large must the electric field be to produce a 1.00-mV (rms) voltage between the ends of the antenna? What is the rate of energy transport per square meter?

General Problems

- 37. If the Sun were to disappear or somehow radically change its output, how long would it take for us on Earth to learn about it?
- 38. Light is emitted from an ordinary lightbulb filament in wave-train bursts about 10^{-8} s in duration. What is the length in space of such wave trains?
- 39. (a) How long did it take for a message sent from Earth to reach the first astronauts on the Moon? (b) How long will it take for a message from Earth to reach the first astronauts who arrive on Mars; assume Mars is at its closest approach to Earth (78 \times 10⁶ km)?
- 40. A radio voice signal from the Apollo crew on the Moon (Fig. 22-20) was beamed to a listening crowd from a radio speaker. If you were standing 25 m from the loudspeaker, what was the total time lag between when you heard the sound and when the sound left the Moon?

FIGURE 22-20 Problem 40.

- *41. Cosmic microwave background radiation fills all space with an average energy density of 4×10^{-14} J/m³. (a) Find the rms value of the electric field associated with this radiation. (b) How far from a 10-kW radio transmitter emitting uniformly in all directions would you find a comparable value?
- *42. What are E_0 and B_0 2.00 m from a 95-W light source? Assume the bulb emits radiation of a single frequency uniformly in all directions.
- *43. Estimate the rms electric field in the sunlight that hits Mars, knowing that the Earth receives about $1350 \,\mathrm{W/m^2}$ and that Mars is 1.52 times farther from the Sun (on average) than is the Earth.
- *44. At a given instant in time, a traveling EM wave is noted to have its maximum magnetic field pointing west and its maximum electric field pointing south. In which direction is the wave traveling? If the rate of energy flow is 560 W/m^2 , what are the maximum values for the two fields?
- *45. Estimate how long an AM antenna would have to be if it were (a) $\frac{1}{2}\lambda$ or (b) $\frac{1}{4}\lambda$. AM radio is roughly 1 MHz (530 kHz to 1.7 MHz).

Answers to Exercises

A: (a) 3.8×10^6 Hz; (b) 5.5×10^{18} Hz. **B**: 45 cm.

- * 46. How large an emf (rms) will be generated in an antenna that consists of a 380-loop circular coil of wire 2.2 cm in diameter if the EM wave has a frequency of 810 kHz and is transporting energy at an average rate of 1.0×10^{-4} W/m² at the antenna? [*Hint*: you can use Eq. $21-5$ for a generator, since it could be applied to an observer moving with the coil so that the magnetic field is oscillating with the frequency $f = \omega/2\pi$.
- * 47. The average intensity of a particular TV station's signal is 1.0×10^{-13} W/m² when it arrives at a 33-cm-diameter satellite TV antenna. (a) Calculate the total energy received by the antenna during 6.0 hours of viewing this station's programs. (b) What are the amplitudes of the E and B fields of the EM wave?
- *48. 15 km from a radio station's transmitting antenna, the amplitude of the electric field is 0.12 V/m . What is the average power output of the radio station?
- *49. The variable capacitance of a radio tuner consists of six plates connected together placed alternately between six other plates, also connected together (Fig. 22-21). Each

plate is separated from its neighbor by 1.1 mm of air. One set of plates can move so that the area of overlap varies from 1.0 cm^2 to 9.0 cm². (a) Are these capacitors connected in series or in parallel? (b) Determine the range of capacitance values. (c) What value of inductor is needed if the radio is to tune AM stations from 550 kHz FIGURE 22-21 to 1600 kHz?

- * 50. A radio station is allowed to broadcast at an average power not to exceed 25 kW. If an electric field amplitude of 0.020 V/m is considered to be acceptable for receiving the radio transmission, estimate how many kilometers away you might be able to hear this station.
- $*51.$ A point source emits light energy uniformly in all directions at an average rate P_0 with a single frequency f. Show that the peak electric field in the wave is given by

$$
E_0 = \sqrt{\frac{\mu_0 c P_0}{2\pi r^2}}
$$

- * 52. Suppose a 50-kW radio station emits EM waves uniformly in all directions. (a) How much energy per second crosses a 1.0-m² area 100 m from the transmitting antenna? (b) What is the rms magnitude of the \vec{E} field at this point, assuming the station is operating at full power? (c) What is the voltage induced in a 1.0-m-long vertical car antenna at this distance?
- * 53. Repeat Problem 52 for a distance of 100 km from the station.
- * 54. What is the maximum power level of the radio station of Problem 52 so as to avoid electrical breakdown of air at a distance of 1.0 m from the antenna? Assume the antenna is a point source. Air breaks down in an electric field of about 3×10^6 V/m. [*Hint*: see Problem 51.]

C: 3 hours.

Reflection from still water, as from a glass mirror, can be analyzed using the ray model of light.

Is this picture right side up? How can vou tell? What are the clues? Ray diagrams, which we will learn to draw in this Chapter, can provide the answer $(=$ upside down).

In this first Chapter on light and optics, we use the ray model of light to understand the formation of images by mirrors, both plane and curved (spherical), as well as by lenses, which are the crucial part of so many optical instruments.

Light: Geometric Optics

 $\overline{}$

CHAPTER

Light arrives at our eyes (1) from a source, (2) by reflection

he sense of sight is extremely important to us, for it provides us with a large part of our information about the world. How do we see? What is the something called *light* that enters our eyes and causes the sensation of sight? How does light behave so that we can see everything that we do? We saw in Chapter 22 that light can be considered a form of electromagnetic radiation. We now examine the subject of light in detail in the next three Chapters.

We see an object in one of two ways: (1) the object may be a *source* of light, such as a lightbulb, a flame, or a star, in which case we see the light emitted directly from the source; or, more commonly, (2) we see an object by light *reflected* from it. In the latter case, the light may have originated from the Sun, artificial lights, or a campfire. An understanding of how bodies *emit* light was not achieved until the 1920s, and will be discussed in Chapter 27. How light is reflected from objects was understood much earlier, and will be discussed in Section 23–2.

-1 The Ray Model of Light

A great deal of evidence suggests that light travels in straight lines under a wide variety of circumstances. For example, a point source of light like the Sun casts distinct shadows, and the beam of a flashlight appears to be a straight line. In fact, we infer the positions of objects in our environment by assuming that light moves from the object to our eyes in straight-line paths. Our orientation to the physical world is based on this assumption.

This reasonable assumption has led to the ray model of light. This model assumes that light travels in straight-line paths called light rays. Actually, a ray is an idealization; it is meant to represent an extremely narrow beam of light.

Light rays

When we see an object, according to the ray model, light reaches our eyes from each point on the object. Although light rays leave each point in many different directions, normally only a small bundle of these rays can enter the pupil of an observer's eye, as shown in Fig. 23–1. If the person's head moves to one side, a different bundle of rays will enter the eye from each point.

We saw in Chapter 22 that light can be considered as an electromagnetic wave. Although the ray model of light does not deal with this aspect of light (we discuss the wave nature of light in Chapter 24), the ray model has been very successful in describing many aspects of light such as reflection, refraction, and the formation of images by mirrors and lenses. Because these explanations involve straight-line rays at various angles, this subject is referred to as **geometric optics**.

23–2 Reflection; Image Formation by a Plane Mirror

When light strikes the surface of an object, some of the light is reflected. The rest can be absorbed by the object (and transformed to thermal energy) or, if the object is transparent like glass or water, part can be transmitted through. For a very shiny object such as a silvered mirror, over 95% of the light may be reflected.

When a narrow beam of light strikes a flat surface (Fig. 23-2), we define the **angle of incidence,** θ_i , to be the angle an incident ray makes with the normal (perpendicular) to the surface, and the **angle of reflection,** θ_r , to be the angle the reflected ray makes with the normal. It is found that the incident and reflected rays lie in the same plane with the normal to the surface, and that

the angle of reflection equals the angle of incidence, $\theta_r = \theta_i$.

This is the law of reflection, and it is depicted in Fig. $23-2$. It was known to the ancient Greeks, and you can confirm it yourself by shining a narrow flashlight beam at a mirror in a darkened room.

When light is incident upon a rough surface, even microscopically rough such as this page, it is reflected in many directions, Fig. 23–3. This is called diffuse reflection. The law of reflection still holds, however, at each small section of the surface. Because of diffuse reflection in all directions, an ordinary object can be seen at many different angles by the light reflected from it. When you move your head to the side, different reflected rays reach your eye from each point on the object (such as this page), Fig. 23-4a. Let us compare diffuse reflection to reflection from a mirror, which is known as specular reflection. ("Speculum" is Latin for mirror.) When a narrow beam of light shines on a mirror, the light will not reach your eye unless your eye is positioned at just the right place where the law of reflection is satisfied, as shown in Fig. 23–4b. This is what gives rise to the special image-forming properties of mirrors.

FIGURE 23-1 Light rays come from each single point on an object. A small bundle of rays leaving one point is shown entering a person's eye.

FIGURE 23-2 Law of reflection: (a) Shows a 3-D view of an incident rav being reflected at the top of a flat surface; (b) shows a side or "end-on" view, which we will usually use because of its clarity.

Angles of incidence and reflection (measure to \perp at surface)

Law of reflection

FIGURE 23-3 Diffuse reflection from a rough surface.

FIGURE 23-4 A beam of light from a flashlight shines on (a) white paper, and (b) a mirror. In part (a), you can see the white light reflected at various positions because of diffuse reflection. But in part (b), you see the reflected light only when your eye is placed correctly ($\theta_r = \theta_i$); this is known as specular reflection. (Galileo, using similar arguments, showed that the Moon must have a rough surface rather than a highly polished surface like a mirror, as some people thought.)

SECTION 23-2 633

FIGURE 23-5 When you look in a mirror, you see an image of yourself and objects around you. You don't see vourself as others see vou, because left and right appear reversed in the image.

When you look straight into a mirror, you see what appears to be yourself as well as various objects around and behind you, Fig. 23–5. Your face and the other objects look as if they are in front of you, beyond the mirror; but they aren't. What you see in the mirror is an **image** of the objects, including yourself, that are in front of the mirror.

A "plane" mirror is one with a smooth flat reflecting surface. Figure 23–6 shows how an image is formed by a plane mirror according to the ray model. We are viewing the mirror, on edge, in the diagram of Fig. 23–6, and the rays are shown reflecting from the front surface. (Good mirrors are generally made by putting a highly reflective metallic coating on one surface of a very flat piece of glass.) Rays from two different points on an object (a bottle) are shown in Fig. 23–6: two rays are shown leaving from a point on the top of the bottle, and two more from a point on the bottom. Rays leave each point on the object going in many directions, but only those that enclose the bundle of rays that enter the eye from each of the two points are shown. Each set of diverging rays that enter the eye appear to come from a single point (called the image point) behind the mirror, as shown by the dashed lines. That is, our eyes and brain interpret any rays that enter an eye as having traveled straightline paths. The point from which each bundle of rays seems to come is one point on the image. For each point on the object, there is a corresponding image point.

FIGURE 23-6 Formation of a virtual image by a plane mirror.

Image distance = object distance (plane mirror)

Real and virtual images

Let us concentrate on the two rays that leave point A on the object in Fig. 23–6, and strike the mirror at points B and B'. We use geometry now, for the rays at B. The angles ADB and CDB are right angles; and because of the law of reflection, $\theta_i = \theta_r$ at point B. Therefore, by geometry, angles ABD and CBD are also equal. The two triangles ABD and CBD are thus congruent, and the length $AD = CD$. That is, the image appears as far behind the mirror as the object is in front. The **image distance**, d_i (distance from mirror to image, Fig. 23–6), equals the object distance, d_0 (distance from object to mirror). From the geometry, we also see that the height of the image is the same as that of the object.

The light rays do not actually pass through the image location itself in Fig. 23–6. (Note where the red lines are dashed to show they are our projections, not rays.) The image would not appear on paper or film placed at the location of the image. Therefore, it is called a **virtual image**. This is to distinguish it from a **real image** in which the light does pass through the image and which therefore could appear on paper or film placed at the image position. Our eyes can see both real and virtual images, as long as the diverging rays enter our pupils. We will see that curved mirrors and lenses can form real images, as well as virtual. A movie projector lens, for example, produces a real image that is visible on the screen.

EXAMPLE 23-1 How tall must a full-length mirror be? A woman 1.60 m tall stands in front of a vertical plane mirror. What is the minimum height of the mirror, and how high must its lower edge be above the floor, if she is to be able to see her whole body? (Assume her eyes are 10 cm below the top of her head.)

FIGURE 23-7 Seeing oneself in a mirror. Example 23-1.

APPROACH For her to see her whole body, light rays from the top of her head and from the bottom of her foot must reflect from the mirror and enter her eye: see Fig. 23-7. We don't show two rays diverging from each point as we did in Fig. 23-6, where we wanted to find where the image is. Now that we know the image is the same distance behind a plane mirror as the object is in front, we only need to show one ray leaving point G (top of head) and one ray leaving point A (her toe), and then use simple geometry.

SOLUTION First consider the ray that leaves her foot at A, reflects at B, and enters the eye at E. The mirror needs to extend no lower than B. Because the angle of reflection equals the angle of incidence, the height BD is half of the height AE. Because $AE = 1.60 \text{ m} - 0.10 \text{ m} = 1.50 \text{ m}$, then $BD = 0.75 \text{ m}$. Similarly, if the woman is to see the top of her head, the top edge of the mirror only needs to reach point F, which is 5 cm below the top of her head (half of $GE = 10$ cm). Thus, $DF = 1.55$ m, and the mirror need have a vertical height of only $(1.55 \text{ m} - 0.75 \text{ m}) = 0.80 \text{ m}$. And the mirror's bottom edge must be 0.75 m above the floor.

NOTE We see that a mirror need be only half as tall as a person for that person to see all of himself or herself.

EXERCISE A Does the result of Example 23-1 depend on the person's distance from the mirror? (Try it and see, it's fun.)

Formation of Images by Spherical Mirrors

Reflecting surfaces do not have to be flat. The most common *curved* mirrors are *spherical*, which means they form a section of a sphere. A spherical mirror is called **convex** if the reflection takes place on the outer surface of the spherical shape so that the center of the mirror surface bulges out toward the viewer (Fig. 23–8a). A mirror is called **concave** if the reflecting surface is on the inner surface of the sphere so that the center of the mirror sinks away from the viewer (like a "cave"), Fig. 23–8b. Concave mirrors are used as shaving or cosmetic mirrors (Fig. 23–9a), and convex mirrors are sometimes used on cars and trucks (rearview mirrors) and in shops (to watch for thieves), because they take in a wide field of view (Fig. 23–9b).

 (a)

mirror gives a magnified image. (b) A convex mirror in a store reduces image size and so includes a wide field of view.

PHYSICS APPLIED How tall a mirror do you need to see a reflection of your entire self?

SECTION 23-3 Formation of Images by Spherical Mirrors 635

FIGURE 23-10 If the object's distance is large compared to the size of the mirror (or lens), the rays are nearly parallel. They are parallel for an object at infinity (∞) .

FIGURE 23-11 Parallel rays striking a concave spherical mirror do not focus at precisely a single point. (This "defect" is referred to as "spherical aberration.")

FIGURE 23-12 Rays parallel to the principal axis of a concave spherical mirror come to a focus at F, the focal point, as long as the mirror is small in width as compared to its radius of curvature, r , so that the rays are "paraxial"—that is, make only small angles with the axis.

Focal length of mirror

Parabolic mirror

Focal Point and Focal Length

To see how spherical mirrors form images, we first consider an object that is very far from a concave mirror. For a distant object, as shown in Fig. 23–10, the rays from each point on the object that strike the mirror will be nearly parallel. For an object infinitely far away (the Sun and stars approach this), the rays would be precisely parallel. Now consider such parallel rays falling on a concave mirror as in Fig. 23–11. The law of reflection holds for each of these rays at the point each strikes the mirror. As can be seen, they are not all brought to a single point. In order to form a sharp image, the rays must come to a point. Thus a spherical mirror will not make as sharp an image as a plane mirror will. However, as we show below, if the mirror is small compared to its radius of curvature, so that a reflected ray makes only a small angle with the incident ray (2θ in Fig. 23-12), then the rays will cross each other at very nearly a single point, or focus. In the case shown in Fig. $23-12$, the rays are parallel to the **principal axis**, which is defined as the straight line perpendicular to the curved surface at its center (line CA in the diagram). The point F, where incident parallel rays come to a focus after reflection, is called the **focal point** of the mirror. The distance between F and the center of the mirror, length FA, is called the focal length, f , of the mirror. The focal point is also the *image point for an object infinitely far away* along the principal axis. The image of the Sun, for example, would be at F.

Now we will show, for a mirror whose reflecting surface is small compared to its radius of curvature, that the rays very nearly meet at a common point, F, and we will also calculate the focal length f . In this approximation, we consider only rays that make a small angle with the principal axis; such rays are called paraxial rays, and their angles are exaggerated in Fig. 23-12 to make the labels clear. First we consider a ray that strikes the mirror at B in Fig. $23-12$. The point C is the center of curvature of the mirror (the center of the sphere of which the mirror is a part). So the dashed line CB is equal to r , the radius of curvature, and CB is normal to the mirror's surface at B. The incoming ray that hits the mirror at B makes an angle θ with this normal, and hence the reflected ray, BF, also makes an angle θ with the normal (law of reflection). Note that angle BCF is also θ as shown. The triangle CBF is isosceles because two of its angles are equal. Thus we have length $CF = BF$. We assume the mirror surface is small compared to the mirror's radius of curvature, so the angles are small, and the length FB is nearly equal to length FA. In this approximation, $FA = FC$. But $FA = f$, the focal length, and $CA = 2 \times FA = r$. Thus the focal length is half the radius of curvature:

$$
f = \frac{7}{2}.\tag{23-1}
$$

We assumed only that the angle θ was small, so this result applies for all other incident paraxial rays. Thus all paraxial rays pass through the same point F.

Since it is only approximately true that the rays come to a perfect focus at F, the more curved the mirror, the worse the approximation (Fig. $23-11$) and the more blurred the image. This "defect" of spherical mirrors is called spherical aberration; we will discuss it more with regard to lenses in Chapter 25. A *parabolic* reflector, on the other hand, will reflect the rays to a perfect focus. However, because parabolic shapes are much harder to make and thus much more expensive, spherical mirrors are used for most purposes. (Many astronomical telescopes use parabolic reflectors.) We consider here only spherical mirrors and we will assume that they are small compared to their radius of curvature so that the image is sharp and Eq. 23-1 holds.

Image Formation-Ray Diagrams

We saw that for an object at infinity, the image is located at the focal point of a concave spherical mirror, where $f = r/2$. But where does the image lie for an object not at infinity? First consider the object shown as an arrow in Fig. 23-13, which is placed between F and C at point O (O for object). Let us determine where the image will be for a given point O' at the top of the object. To do this we can draw several rays and make sure these reflect from the mirror such that the angle of reflection equals the angle of incidence. Many rays could be drawn leaving any point on an object, but determining the image position is simplified if we deal with three particularly simple rays. These are the rays labeled 1, 2, and 3 in Fig. 23–13 and we draw them leaving object point O' as follows:

Ray 1 is drawn parallel to the axis; therefore after reflection it must pass along a line through F (as we saw in Fig. 23–12, and drawn here in Fig. 23–13a). Ray 2 leaves O' and is made to pass through F; therefore it must reflect so it is parallel to the axis (Fig. 23–13b).

Ray 3 passes through C, the center of curvature; it is along a radius of the spherical surface and is perpendicular to the mirror, so it is reflected back on itself (Fig. $23-13c$).

All three rays leave a single point O' on the object. After reflection from a (small) mirror, the point at which these rays cross is the image point I'. All other rays from the same object point will also pass through this image point. To find the image point for any object point, only these three types of rays need to be drawn. Only two of these rays are needed, but the third serves as a check. RAY DIAGRAM

Finding the image position for a curved mirror

FIGURE 23-13 Rays leave point O' on the object (an arrow). Shown are the three most useful rays for determining where the image I' is formed. [Note that our mirror is not small compared to f , so our diagram will not give the precise position of the image.]

We have shown the image point in Fig. $23-13$ only for a single point on the object. Other points on the object are imaged nearby, so a complete image of the object is formed, as shown by the dashed arrow in Fig. 23-13c. Because the light actually passes through the image itself, this is a *real image* that will appear on a piece of paper or film placed there. This can be compared to the virtual image formed by a plane mirror (the light does not actually pass through that image, Fig. 23–6).

The image in Fig. 23–13 can be seen by the eye when the eye is placed to the left of the image so that some of the rays diverging from each point on the image (as point I') can enter the eye as shown in Fig. 23–13c. (See also Figs. 23–1 and 23–6.) Real image

Mirror Equation and Magnification

Image points can be determined, roughly, by drawing the three rays as just described, Fig. 23–13; but it is difficult to draw small angles for the "paraxial" rays as we assumed. For more accurate results, we now derive an equation that gives the image distance if the object distance and radius of curvature of the mirror are known. To do this, we refer to Fig. 23-14. The object distance, d_0 , is the distance of the object (point O) from the center of the mirror. The **image distance**, d_i , is the distance of the image (point I) from the center of the mirror. The height of the object OO' is called h_0 and the height of the image, I'I, is h_i . Two rays leaving O' are

Distances d_0 and d_i are measured from center of mirror

FIGURE 23-14 Diagram for deriving the mirror equation. For the derivation, we assume the mirror size is small compared to its radius of curvature.

shown: O'FBI' (same as ray 2 in Fig. $23-13$) and O'AI', which is a fourth type of ray that reflects at the center of the mirror and can also be used to find an image point. The ray O'AI' obeys the law of reflection, so the two right triangles O'AO and I'AI are similar. Therefore, we have

$$
\frac{h_o}{h_i} = \frac{d_o}{d_i}.
$$

For the other ray shown, O'FBI', the triangles O'FO and AFB are also similar because the angles are equal and we use the approximation $AB = h_i$ (mirror small compared to its radius). Furthermore $FA = f$, the focal length of the mirror, so

$$
\frac{h_o}{h_i} = \frac{\text{OF}}{\text{FA}} = \frac{d_o - f}{f}.
$$

The left sides of the two preceding expressions are the same, so we can equate the right sides:

$$
\frac{d_{\rm o}}{d_{\rm i}} = \frac{d_{\rm o}-f}{f} \cdot
$$

We now divide both sides by d_0 and rearrange to obtain

Mirror equation

$$
\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f}.
$$
 (23-2)

This is the equation we were seeking. It is called the mirror equation and relates the object and image distances to the focal length f (where $f = r/2$).

The **magnification**, m , of a mirror is defined as the height of the image divided by the height of the object. From our first set of similar triangles above, or the first equation on this page, we can write:

$$
m = \frac{h_{\rm i}}{h_{\rm o}} = -\frac{d_{\rm i}}{d_{\rm o}}.\tag{23-3}
$$

The minus sign in Eq. $23-3$ is inserted as a convention. Indeed, we must

be careful about the signs of all quantities in Eqs. 23–2 and 23–3. Sign conventions are chosen so as to give the correct locations and orientations of images, as predicted by ray diagrams. The sign conventions we use are: the image height h_i is positive if the image is upright, and negative if inverted, relative to the object (assuming h_0 is taken as positive); d_i or d_0 is positive if image or object is in front of the mirror (as in Fig. $23-14$); if either image or object is behind the mirror, the corresponding distance is negative (an example can be seen in Fig. $23-16$, Example $23-3$). Thus the magnification (Eq. $23-3$) is positive for an upright image and negative for an inverted image (upside down). We summarize sign conventions more fully after discussing convex mirrors later in this Section.

EXERCISE B Does the mirror equation, Eq. 23-2, hold for a plane mirror? Explain.

Concave Mirror Examples

EXAMPLE 23-2 Image in a concave mirror. A 1.50-cm-high diamond ring is placed 20.0 cm from a concave mirror with radius of curvature 30.0 cm. Determine (a) the position of the image, and (b) its size.

APPROACH We determine the focal length from the radius of curvature (Eq. 23–1), $f = r/2 = 15.0$ cm. The ray diagram is basically like that shown in Fig. $23-13$ or Fig. $23-14$, since the object is between F and C. The position and size of the image are found from Eqs. 23–2 and 23–3.

SOLUTION Referring to Fig. 23-14, we have $CA = r = 30.0$ cm, $FA = f =$ 15.0 cm, and OA = d_0 = 20.0 cm.

(a) From Eq. $23-2$,

$$
\frac{1}{d_i} = \frac{1}{f} - \frac{1}{d_o} = \frac{1}{15.0 \text{ cm}} - \frac{1}{20.0 \text{ cm}} = 0.0167 \text{ cm}^{-1}.
$$

So $d_i = 1/(0.0167 \text{ cm}^{-1}) = 60.0 \text{ cm}$. Because d_i is positive, the image is 60.0 cm in front of the mirror, on the same side as the object. (b) From Eq. $23-3$, the magnification is

$$
m = -\frac{d_i}{d_o} = -\frac{60.0 \text{ cm}}{20.0 \text{ cm}} = -3.00.
$$

The image height is 3.0 times the object height, and is

$$
h_i = mh_o = (-3.00)(1.5 \text{ cm}) = -4.5 \text{ cm}.
$$

The minus sign reminds us that the image is inverted, as in Fig. 23-14.

NOTE When an object is beyond the focal point of a concave mirror, we can see from Fig. 23–13 or 23–14 that the image is always inverted and real.

For a person's eye to see a sharp image, the eye must be at a place where it intercepts diverging rays from points on the image, as is the case for the eye's position in Figs. $23-13$ and $23-14$. Our eyes are made to see normal objects, which always means the rays are diverging toward the eye as shown in Fig. 23-1. (Or, for very distant objects like stars, the rays become essentially parallel—see Fig. 23-10.) If you placed your eye between points O and I in Fig. 23-14, for example, *converging* rays from the object OO' would enter your eye and the lens of your eye could not bring them to a focus; you would see a blurry image. We will discuss the eye more in Chapter 25.

If you are the object OO' in Fig. 23-14, situated between F and C, and are trying to see yourself in the mirror, you would see a blur; but the person whose eye is shown in Fig. 23–14 can see you clearly. You can see yourself clearly, but upside down, if you are to the left of C in Fig. 23–14, so $d_0 > 2f$. Why? Because then the rays reflected from the image will be *diverging* at your position as shown in Fig. 23-15, and your eye can focus them. You can also see yourself clearly, and right-side up, if you are closer to the mirror than its focal point $(d_0 < f)$, as we will see in Example 23–3, Fig. 23–16.

FIGURE 23-15 You can see a clear inverted image of your face when you are beyond C ($d_0 > 2f$), because the ravs that arrive at your eve are diverging. Standard rays 2 and 3 are shown leaving point O on your nose. Ray 2 (and other nearby rays) enters your eye. Notice that rays are diverging as they move to the left of image point I.

CAUTION Sign conventions

FIGURE 23-16 Object placed within the focal point F. The image is behind the mirror and is virtual, Example 23-3. [Note that the vertical scale (height of object = 1.0 cm) is different from the horizontal $(OA = 10.0 \text{ cm})$ for ease of drawing, and affects the precision of the drawing.]

EXAMPLE 23-3 Object closer to concave mirror. A 1.00-cm-high object is placed 10.0 cm from a concave mirror whose radius of curvature is 30.0 cm. (a) Draw a ray diagram to locate (approximately) the position of the image. (b) Determine the position of the image and the magnification analytically.

APPROACH We draw the ray diagram using the rays of Fig. 23–13. An analytic solution uses Eqs. 23-1, 23-2, and 23-3.

SOLUTION (a) Since $f = r/2 = 15.0$ cm, the object is between the mirror and the focal point. We draw the three rays as described earlier (Fig. $23-13$); they are shown leaving the tip of the object in Fig. $23-16$. Ray 1 leaves the tip of our object heading toward the mirror parallel to the axis, and reflects through F. Ray 2 cannot head toward F because it would not strike the mirror; so ray 2 must point as if it started at F (dashed line) and heads to the mirror, and then is reflected parallel to the principal axis. Ray 3 is perpendicular to the mirror, as before. The rays reflected from the mirror diverge and so never meet at a point. They appear, however, to be coming from a point behind the mirror. This point locates the image of the tip of the arrow. The image is thus behind the mirror and *virtual*. (Why?) (b) We use Eq. 23–2 to find d_i when $d_o = 10.0$ cm:

$$
\frac{1}{d_i} = \frac{1}{f} - \frac{1}{d_o} = \frac{1}{15.0 \text{ cm}} - \frac{1}{10.0 \text{ cm}} = \frac{2 - 3}{30.0 \text{ cm}} = -\frac{1}{30.0 \text{ cm}}.
$$

Therefore, $d_i = -30.0$ cm. The minus sign means the image is behind the mirror. The magnification is $m = -d_i/d_0 = -(-30.0 \text{ cm})/(10.0 \text{ cm}) = +3.00$. So the image is 3.00 times larger than the object. The plus sign indicates that the image is upright (same as object), which is consistent with the ray diagram, Fig. 23–16).

NOTE The image distance cannot be obtained accurately by measuring on Fig. 23–16, because our diagram violates the paraxial ray assumption (so as to make all rays clearly visible).]

NOTE When the object is located inside the focal point of a concave mirror $(d_0 < f)$, the image is always upright and vertical. And if the object O in Fig. 23-16 is you, you see yourself clearly, because the reflected rays at O are diverging. Your image is upright and enlarged.

It is useful to compare Figs. $23-13$ and $23-16$. We can see that if the object is within the focal point $(d_0 < f)$, as in Fig. 23–16, the image is virtual, upright, and magnified. This is how a shaving or cosmetic mirror is used—you must place your head closer to the mirror than the focal point if you are to see yourself right-side up (Fig. $23-9a$). If the object is *beyond* the focal point, as in Fig. 23–13, the image is real and inverted (upside down—and hard to use!). Whether the magnification is greater or less than 1.0 in the latter case depends on the position of the object relative to the center of curvature, point C.

Seeing yourself upright and magnified in a concave mirror

Magnifying mirror (shaving/cosmetic)

Convex Mirrors

The analysis used for concave mirrors can be applied to **convex** mirrors. Even the mirror equation (Eq. $23-2$) holds for a convex mirror, although the quantities involved must be carefully defined. Figure 23-17a shows parallel rays falling on a convex mirror. Again spherical aberration will be present (Fig. $23-11$), but we assume the mirror's size is small compared to its radius of curvature. The reflected rays diverge, but seem to come from point F behind the mirror. This is the focal point, and its distance from the center of the mirror is the **focal length**, f. It is easy to show that again $f = r/2$. We see that an object at infinity produces a virtual image in a convex mirror. Indeed, no matter where the object is placed on the reflecting side of a convex mirror, the image will be virtual and upright, as indicated in Fig. 23–17b. To find the image we draw rays 1 and 3 according to the rules used before on the concave mirror, as shown in Fig. 23–17b. Note that although rays 1 and 3 don't actually pass through points F and C, the line along which each is drawn does (shown dashed).

The mirror equation, Eq. 23-2, holds for convex mirrors but the focal length f must be considered negative, as must the radius of curvature. The proof is left as a Problem. It is also left as a Problem to show that Eq. 23-3 for the magnification is also valid.

FIGURE 23-17 Convex mirror: (a) the focal point is at F, behind the mirror; (b) the image I of the object at O is virtual, upright, and smaller than the object. [Not to scale for Example 23-4.]

PROBLEM SOLVING Spherical Mirrors

- 1. Always draw a ray diagram even though you are going to make an analytic calculation—the diagram serves as a check, even if not precise. From one point on the object, draw at least two. preferably three, of the easy-to-draw rays using the rules described in Fig. $23-13$. The image point is where the reflected rays intersect or appear to intersect.
- 2. Apply the mirror equation, Eq. 23-2, and the magnification equation, Eq. 23-3. It is crucially important to follow the sign conventions—next point.

3. Sign Conventions

- (a) When the object, image, or focal point is on the reflecting side of the mirror (on the left in our drawings), the corresponding distance is positive. If any of these points is behind the mirror (on the right) the corresponding distance is negative.[†]
- (b) The image height h_i is positive if the image is upright, and negative if inverted, relative to the object $(h_0$ is always taken as positive).
- 4. Check that the analytical solution is consistent with the ray diagram.

[†]Object distances are positive for material objects, but can be negative in systems with more than one mirror or lens—see Section 23–9.

EXAMPLE 23-4 Convex rearview mirror. An external rearview car mirror is convex with a radius of curvature of 16.0 m (Fig. 23–18). Determine the location of the image and its magnification for an object 10.0 m from the mirror.

APPROACH We follow the steps of the Problem Solving Box explicitly.

SOLUTION (1) Draw a ray diagram: The ray diagram will be like Fig. 23-17, but the large object distance $(d_0 = 10.0 \text{ m})$ makes a precise drawing difficult. We have a convex mirror, so r is negative by convention.

(2) Mirror and magnification equations: The center of curvature of a convex mirror is behind the mirror, as is its focal point, so we set $r = -16.0$ m so that the focal length is $f = r/2 = -8.0$ m. The object is in front of the mirror, $d_0 = 10.0$ m. Solving the mirror equation, Eq. 23–2, for $1/d_i$ gives

$$
\frac{1}{d_i} = \frac{1}{f} - \frac{1}{d_o} = \frac{1}{-8.0 \text{ m}} - \frac{1}{10.0 \text{ m}} = \frac{-10.0 - 8.0}{80.0 \text{ m}} = -\frac{18}{80.0 \text{ m}}.
$$

Thus $d_i = -80.0 \text{ m}/18 = -4.4 \text{ m}$. Equation 23-3 gives the magnification

$$
m = -\frac{d_i}{d_o} = -\frac{(-4.4 \text{ m})}{(10.0 \text{ m})} = +0.44
$$

(3) Sign conventions: The image distance is negative, -4.4 m, so the image is *behind* the mirror. The magnification is $m = +0.44$, so the image is *upright* (same orientation as object) and less than half as tall as the object. (4) Check: Our results are consistent with Fig. 23–17b.

 \overline{A} PHYSICS APPLIED Convex rearview mirror

FIGURE 23-18 Example 23-4.

Convex rearview mirrors on vehicles sometimes come with a warning that objects are closer than they appear in the mirror. The fact that d_i may be smaller than d_0 (as in this Example) seems to contradict this observation. The real reason the object seems farther away is that its image in the convex mirror is *smaller*, and we judge distance of ordinary objects such as other cars mostly by their size.

23-4 Index of Refraction

We saw in Chapter 22 that the speed of light in vacuum is

 $c = 2.99792458 \times 10^8 \,\mathrm{m/s}$,

which we usually round off to

 $c = 3.00 \times 10^8 \,\mathrm{m/s}$

when extremely precise results are not required. This speed applies to all electromagnetic waves, including visible light.

In air the speed is only slightly less. In other transparent materials, such as glass and water, the speed is always less than that in vacuum. For example, in water light travels at about $\frac{3}{4}c$. The ratio of the speed of light in vacuum to the speed v in a given material is called the **index of refraction**, n , of that material:

$$
n = \frac{c}{v}.\tag{23-4}
$$

The index of refraction is never less than 1, and values for various materials are given in Table $23-1$. As we shall see later, *n* varies somewhat with the wavelength of the light—except in vacuum—so a particular wavelength is specified in the Table, that of yellow light with wavelength $\lambda = 589$ nm.

EXAMPLE 23-5 Light's speed in diamond. Calculate the speed of light in diamond.

APPROACH We use Eq. 23-4, finding from Table 23-1 that $n = 2.42$ for diamond.

SOLUTION The speed of light traveling inside a diamond is

$$
v = \frac{c}{n} = \frac{c}{2.42} = 0.413c
$$

or

$$
v = \frac{3.00 \times 10^8 \text{ m/s}}{2.42}
$$

$$
= 1.24 \times 10^8 \text{ m/s}.
$$

That light travels more slowly in matter than in vacuum can be explained at the atomic level as being due to the absorption and reemission of light by atoms and molecules of the material.

23-5 Refraction: Snell's Law

When light passes from one transparent medium into another with a different index of refraction, part of the incident light is reflected at the boundary. The remainder passes into the new medium. If a ray of light is incident at an angle to the surface (other than perpendicular), the ray changes direction as it enters the new medium. This change in direction, or bending, is called refraction.

Medium $n = c/v$

Indices of Refraction⁺

TABLE 23-1

Index of refraction

642 CHAPTER 23 Light: Geometric Optics

FIGURE 23-19 Refraction. (a) Light refracted when passing from air (n_1) into water (n_2) : $n_2 > n_1$. (b) Light refracted when passing from water (n_1) into air (n_2) : $n_1 > n_2$.

Figure 23–19a shows a ray passing from air into water. Angle θ_1 is the angle the incident ray makes with the normal (perpendicular) to the surface and is called the angle of incidence. Angle θ_2 is the angle of refraction, the angle the refracted ray makes with the normal to the surface. Notice that the ray bends toward the normal when entering the water. This is always the case when the rav enters a medium where the speed of light is less (and the index of refraction greater, Eq. 23-4). If light travels from one medium into a second where its speed is *greater*, the ray bends away from the normal; this is shown in Fig. 23–19b for a ray traveling from water to air.

FIGURE 23-20 Ray diagram showing why a person's legs look shorter when standing in waist-deep water: the path of light traveling from the bather's foot to the observer's eye bends at the water's surface, and our brain interprets the light as having traveled in a straight line, from higher up (dashed line).

Refraction is responsible for a number of common optical illusions. For example, a person standing in waist-deep water appears to have shortened legs. As shown in Fig. 23-20, the rays leaving the person's foot are bent at the surface. The observer's brain assumes the rays to have traveled a straight-line path (dashed red line), and so the feet appear to be higher than they really are. Similarly, when you put a pencil in water, it appears to be bent (Fig. 23–21).

Snell's Law

The angle of refraction depends on the speed of light in the two media and on the incident angle. An analytical relation between θ_1 and θ_2 was arrived at experimentally about 1621 by Willebrord Snell (1591–1626). It is known as **Snell's law** and is written:

$$
n_1\sin\theta_1 = n_2\sin\theta_2.
$$

 $(23-5)$

 θ_1 is the angle of incidence and θ_2 is the angle of refraction; n_1 and n_2 are the respective indices of refraction in the materials. See Fig. 23–19. The incident and refracted rays lie in the same plane, which also includes the perpendicular to the surface. Snell's law is the basic law of refraction. (Snell's law was derived in Section $11-14$ where Eq. 11-20 is just a combination of Eqs. 23-5 and 23-4.)

It is clear from Snell's law that if $n_2 > n_1$, then $\theta_2 < \theta_1$. That is, if light enters a medium where n is greater (and its speed less), then the ray is bent toward the normal. And if $n_2 < n_1$, then $\theta_2 > \theta_1$, so the ray bends away from the normal. This is what we saw in Fig. 23–19.

Angle of refraction

FIGURE 23-21 A pencil in water looks bent even when it isn't.

 π) PHYSICS APPLIED **Optical illusions**

Snell's law (law of refraction)

CAUTION

Angles θ_1 and θ_2 are measured from the perpendicular, not from surface

FIGURE 23-22 Light passing through a piece of glass (Example 23-6).

EXERCISE C Light passes from a medium with $n = 1.3$ into a medium with $n = 1.5$. Is the light bent toward or away from the perpendicular to the interface?

EXAMPLE 23-6 Refraction through flat glass. Light traveling in air strikes a flat piece of uniformly thick glass at an incident angle of 60° , as shown in Fig. 23–22. If the index of refraction of the glass is 1.50, (a) what is the angle of refraction θ_A in the glass; (b) what is the angle θ_B at which the ray emerges from the glass?

APPROACH We apply Snell's law at the first surface, where the light enters the glass, and again at the second surface where it leaves the glass and enters the air. **SOLUTION** (a) The incident ray is in air, so $n_1 = 1.00$ and $n_2 = 1.50$. Applying Snell's law where the light enters the glass ($\theta_1 = 60^\circ$) gives

$$
\sin \theta_{\rm A} = \frac{1.00}{1.50} \sin 60^{\circ} = 0.577,
$$

$$
0 \ \theta_{\rm A} = 35.2^{\circ}.
$$

(b) Since the faces of the glass are parallel, the incident angle at the second surface is just θ_A (simple geometry), so $\sin \theta_A = 0.577$. At this second interface, $n_1 = 1.50$ and $n_2 = 1.00$. Thus the ray re-enters the air at an angle $\theta_{\rm B}$ (= θ_2) given by

$$
\sin \theta_{\rm B} = \frac{1.50}{1.00} \sin \theta_{\rm A} = 0.866,
$$

and $\theta_B = 60^\circ$. The direction of a light ray is thus unchanged by passing through a flat piece of glass of uniform thickness.

NOTE It should be clear that this works for any angle of incidence. The ray is displaced slightly to one side, however. You can observe this by looking through a piece of glass (near its edge) at some object and then moving your head to the side slightly so that you see the object directly. It "jumps."

EXAMPLE 23-7 Apparent depth of a pool. A swimmer has dropped her goggles to the bottom of a pool at the shallow end, marked as 1.0 m deep. But the goggles don't look that deep. Why? How deep do the goggles appear to be when you look straight down into the water?

APPROACH We draw a ray diagram showing two rays going upward from a point on the goggles at a small angle, and being refracted at the water's (flat) surface. This is shown in Fig. 23-23, and the dashed lines show why the water seems less deep than it actually is. The two rays traveling upward from the goggles are refracted *away* from the normal as they exit the water, and so appear to be diverging from a point above the goggles (dashed lines).

SOLUTION To calculate the apparent depth d' (Fig. 23–23), given a real depth $d = 1.0$ m, we use Snell's law with $n_1 = 1.33$ for water and $n_2 = 1$ for air.

$$
\sin \theta_2 = n_1 \sin \theta_1.
$$

We are considering only small angles, so $\sin \theta \approx \tan \theta \approx \theta$, with θ in radians. So Snell's law becomes

$$
\theta_2 \approx n_1 \theta
$$

 $rac{x}{d'} \approx n_1 \frac{x}{d}$

From Fig. 23-23, we see that

$$
\theta_2 \approx \tan \theta_2 = \frac{x}{d'}
$$
 and $\theta_1 \approx \tan \theta_1 = \frac{x}{d}$.

Putting these into Snell's law, $\theta_2 \approx n_1 \theta_1$, we get

$$
\mathbf{1}^{\prime}
$$

Οľ

$$
d' \approx \frac{d}{n_1} = \frac{1.0 \text{ m}}{1.33} = 0.75 \text{ m}.
$$

The pool seems only three-fourths as deep as it actually is.

23-6 Total Internal Reflection; Fiber Optics

When light passes from one material into a second material where the index of refraction is less (say, from water into air), the light bends away from the normal, as for rays I and J in Fig. 23-24. At a particular incident angle, the angle of refraction will be 90° , and the refracted ray would skim the surface (ray K) in this case. The incident angle at which this occurs is called the **critical angle**, θ_c . From Snell's law, θ_c is given by

$$
\sin \theta_{\rm C} = \frac{n_2}{n_1} \sin 90^\circ = \frac{n_2}{n_1}.
$$

For any incident angle less than θ_c , there will be a refracted ray, although part of the light will also be reflected at the boundary. However, for incident angles greater than θ_c , Snell's law would tell us that $\sin \theta_2$ is greater than 1.00. Yet the sine of an angle can never be greater than 1.00. In this case there is no refracted ray at all, and all of the light is reflected, as for ray L in Fig. 23-24. This effect is called total internal reflection. But note that total internal reflection can occur only when light strikes a boundary where the medium beyond has a lower index of refraction.

FIGURE 23-24 Since $n_2 < n_1$, light rays are totally internally reflected if the incident angle $\theta_1 > \theta_C$, as for ray L. If $\theta_1 < \theta_{\rm C},$ as for rays I and J, only a part of the light is reflected, and the rest is refracted.

CONCEPTUAL EXAMPLE 23-8 View up from under water. Describe what a person would see who looked up at the world from beneath the perfectly smooth surface of a lake or swimming pool.

RESPONSE For an air-water interface, the critical angle is given by

$$
\sin \theta_{\rm C} = \frac{1.00}{1.33} = 0.750.
$$

Therefore, $\theta_C = 49^\circ$. Thus the person would see the outside world compressed into a circle whose edge makes a 49° angle with the vertical. Beyond this angle, the person would see reflections from the sides and bottom of the lake or pool $(Fig. 23-25)$.

EXERCISE D Light traveling in air strikes a glass surface with $n = 1.48$. For what range of angles will total internal reflection occur?

FIGURE 23-25 (a) Light rays, and (b) view looking upward from beneath the water (the surface of the water must be very smooth). Example 23-8.

SECTION 23-6 Total Internal Reflection; Fiber Optics 645

FIGURE 23-27 Light reflected totally at the interior surface of a glass or transparent plastic fiber.

Fiber optics in communications

 \overrightarrow{A} PHYSICS APPLIED Medicine-bronchoscopes, colonoscopes, endoscopes

Many optical instruments, such as binoculars, use total internal reflection within a prism to reflect light. The advantage is that very nearly 100% of the light is reflected, whereas even the best mirrors reflect somewhat less than 100%. Thus the image is brighter, especially after several reflections. For glass with $n = 1.50$, $\theta_C = 41.8^\circ$. Therefore, 45° prisms will reflect all the light internally, if oriented as shown in the binoculars of Fig. 23–26.

EXERCISE E If 45° plastic lenses were used in binoculars, what minimum index of refraction must the plastic have?

EXERCISE F What would happen if the 45° glass prisms of Exercise E were immersed in water?

Fiber Optics

Total internal reflection is the principle behind fiber optics. Glass and plastic fibers as thin as a few micrometers in diameter are common. A bundle of such tiny fibers is called a **light pipe** or cable, and light[†] can be transmitted along it with almost no loss because of total internal reflection. Figure 23-27 shows how light traveling down a thin fiber makes only glancing collisions with the walls so that total internal reflection occurs. Even if the light pipe is bent into a complicated shape, the critical angle still won't be exceeded, so light is transmitted practically undiminished to the other end. Very small losses do occur, mainly by reflection at the ends and absorption within the fiber.

Important applications of fiber-optic cables are in communications and medicine. They are used in place of wire to carry telephone calls, video signals, and computer data. The signal is a modulated light beam (a light beam whose intensity can be varied) and data is transmitted at a much higher rate and with less loss and less interference than an electrical signal in a copper wire. Fibers have been developed that can support over one hundred separate wavelengths, each modulated to carry up to 10 gigabits $(10^{10}$ bits) of information per second. That amounts to a terabit $(10^{12}$ bits) per second for the full one hundred wavelengths. The sophisticated use of fiber optics to transmit a clear picture is particularly useful in medicine, Fig. 23–28. For example, a patient's lungs can be examined by inserting a light pipe known as a bronchoscope through the mouth and down the bronchial tube. Light is sent down an outer set of fibers to illuminate the lungs. The reflected light returns up a central core set of fibers. Light directly in front of each fiber travels up that fiber. At the opposite end, a viewer sees a series of bright and dark spots, much like a TV screen—that is, a picture of what lies at the opposite end. Lenses are used at each end: at the object end to bring the rays in parallel, and at the viewing end as a telescope. The image may be viewed directly or on a monitor screen or film. The fibers must be optically insulated from one another, usually by a thin coating of material with index of refraction less than that of the fiber. The more fibers there are, and the smaller they are, the more detailed the picture. Such instruments, including bronchoscopes, colonoscopes (for viewing the colon), and endoscopes (stomach or other organs), are extremely useful for examining hard-to-reach places.

[†]Fiber optics finds use not only with visible light but also with infrared light, ultraviolet light, and microwaves.

 (b)

FIGURE 23-28 (a) How a fiberoptic image is made. (b) Example of a fiber-optic device inserted through the nose, and the image seen.

 (d)

Thin Lenses; Ray Tracing

The most important simple optical device is no doubt the thin lens. The development of optical devices using lenses dates to the sixteenth and seventeenth centuries, although the earliest record of eyeglasses dates from the late thirteenth century. Today we find lenses in eyeglasses, cameras, magnifying glasses, telescopes, binoculars, microscopes, and medical instruments. A thin lens is usually circular, and its two faces are portions of a sphere. (Although cylindrical surfaces are also possible, we will concentrate on spherical.) The two faces can be concave, convex, or plane; several types are shown in Fig. 23–29, in cross section. The importance of lenses is that they form images of objects, as shown in Fig. 23-30.

FIGURE 23-30 Converging lens (in holder) forms an image (large "F" on screen at right) of a bright object (illuminated "F" at the left).

> FIGURE 23-31 (below) Parallel rays are brought to a focus by a converging thin lens.

Axis (a) Axis (b)

Consider parallel rays striking the double convex lens shown in cross section in Fig. 23-31a. We assume the lens is made of glass or transparent plastic, so its index of refraction is greater than that of the air outside. The axis of a lens is a straight line passing through the center of the lens and perpendicular to its two surfaces (Fig. 23–31). From Snell's law, we can see that each ray in Fig. 23–31a is bent toward the axis when the ray enters the lens and again when it leaves the lens at the back surface. (Note the dashed lines indicating the normals to each surface for the top ray.) If rays parallel to the axis fall on a thin lens, they will be focused to a point called the focal point, F. This will not be precisely true for a lens with spherical surfaces. But it will be very nearly true—that is, parallel rays will be focused to a tiny region that is nearly a point-if the diameter of the lens is small compared to the radii of curvature of the two lens surfaces. This criterion is satisfied by a thin lens, one that is very thin compared to its diameter, and we consider only thin lenses here.

> SECTION 23-7 Thin Lenses; Ray Tracing 647

Focal length of lens

FIGURE 23-32 Image of the Sun burning a hole, almost, on a piece of paper.

The rays from a point on a distant object are essentially parallel—see Fig. 23-10. Therefore we can say that the focal point is the image point for an object at infinity on the lens axis. Thus, the focal point of a lens can be found by locating the point where the Sun's rays (or those of some other distant object) are brought to a sharp image, Fig. 23–32. The distance of the focal point from the center of the lens is called the **focal length**, f . A lens can be turned around so that light can pass through it from the opposite side. The focal length is *the same* on both sides, as we shall see later, even if the curvatures of the two lens surfaces are different. If parallel rays fall on a lens at an angle, as in Fig. 23–31b, they focus at a point F_a . The plane in which all points such as F and F_a fall is called the **focal plane** of the lens.

Any lens[†] that is thicker in the center than at the edges will make parallel rays converge to a point, and is called a **converging lens** (see Fig. 23–29a). Lenses that are thinner in the center than at the edges (Fig. $23-29b$) are called **diverging lenses** because they make parallel light diverge, as shown in Fig. 23-33. The focal point, F, of a diverging lens is defined as that point from which refracted rays, originating from parallel incident rays, seem to emerge as shown in Fig. 23–33. And the distance from F to the lens is called the **focal length**, f , just as for a converging lens.

Optometrists and ophthalmologists, instead of using the focal length, use the reciprocal of the focal length to specify the strength of eyeglass (or contact) lenses. This is called the **power**, P , of a lens:

Power of lens

Diopters

formed by a thin lens

 $P = \frac{1}{f}$ $(23-7)$

The unit for lens power is the **diopter** (D), which is an inverse meter: $1 D = 1 m^{-1}$. For example, a 20-cm-focal-length lens has a power $P = 1/(0.20 \text{ m}) = 5.0 \text{ D}$. We will mainly use the focal length, but we will refer again to the power of a lens when we discuss eyeglass lenses in Chapter 25.

The most important parameter of a lens is its focal length f . For a converging lens, f is easily measured by finding the image point for the Sun or other distant objects. Once f is known, the image position can be calculated for any object. To find the image point by drawing rays would be difficult if we had to determine the refractive angles at the front surface of the lens and again at the back surface where the ray exits. We can save ourselves a lot of effort by making use of certain facts we already know, such as that a ray parallel to the axis of the lens passes (after refraction) through the focal point. To determine an image point, we need to consider only the three rays indicated in Fig. 23–34, which uses an arrow (on the left) as the object, and a converging lens forming an image to the right. These rays, emanating from a single point on the object, are drawn as if the lens were infinitely thin, and we show only a single sharp bend at the center line of the lens instead of the refractions at each surface. These three rays are drawn as follows:

Ray 1 is drawn parallel to the axis; therefore it is refracted by the lens so that it passes along a line through the focal point F behind the lens, Fig. 23–34a. (See also Fig. 23–31a.)

Ray 2 is drawn on a line passing through the other focal point F' (front side of lens in Fig. 23–34) and emerges from the lens parallel to the axis, Fig. 23–34b.

Ray 3 is directed toward the very center of the lens, where the two surfaces are essentially parallel to each other; this ray therefore emerges from the lens at the same angle as it entered; as we saw in Example 23–6, the ray would be displaced slightly to one side, but since we assume the lens is thin, we draw ray 3 straight through as shown, Fig. 23–34c.

The point where these three rays cross is the image point for that object point. Actually, any two of these rays will suffice to locate the image point, but drawing the third ray can serve as a check.

^{*}We are assuming the lens has an index of refraction greater than that of the surrounding material, such as a glass or plastic lens in air, which is the usual situation.

Using these three rays for one object point, we can find the image point for that point of the object (the top of the arrow in Fig. 23–34). The image points for all other points on the object can be found similarly to determine the complete image of the object. Because the rays actually pass through the image for the case shown in Fig. $23-34$, it is a **real image** (see page 634). The image could be detected by film, or actually seen on a white surface or screen placed at the position of the image (Fig. $23-35$).

The image can also be seen directly by the eye when the eye is placed behind the image, as shown in Fig. $23-34c$, so that some of the rays diverging from each point on the image can enter the eye. We can see a sharp image only for rays diverging from each point on the image, because we see normal objects when diverging rays from each point enter the eye as shown in Fig. 23-1. Your eye cannot focus rays converging on it; if your eye was positioned between points F and I in Fig. 23-34c, it would not see a clear image. (More about our eyes in Section 25–2.) Figure 23–35 shows an image seen (a) on a screen and (b) directly by the eye (and a camera) placed behind the image.

Seeing the image

FIGURE 23-35 (a) A converging lens can form a real image (here of

Diverging Lens

 Ω

By drawing the same three rays emerging from a single object point, we can determine the image position formed by a diverging lens, as shown in Fig. 23-36. Note that ray 1 is drawn parallel to the axis, but does not pass through the focal point F' behind the lens. Instead it seems to come from the focal point F in front of the lens (dashed line). Ray 2 is directed toward F' and is refracted parallel to the lens axis by the lens. Ray 3 passes directly through the center of the lens. The three refracted rays seem to emerge from a point on the left of the lens. This is the image point, I. Because the rays do not pass through the image, it is a **virtual image**. Note that the eye does not distinguish between real and virtual images—both are visible.

FIGURE 23-36 Finding the image by ray tracing for a diverging lens.

We now derive an equation that relates the image distance to the object distance and the focal length of a thin lens. This equation will make the determination of image position quicker and more accurate than doing ray tracing. Let d_0 be the object distance, the distance of the object from the center of the lens, and d_i be the image distance, the distance of the image from the center of the lens. And let h_0 and h_i refer to the heights of the object and image. Consider the two rays shown in

FIGURE 23-37 Deriving the lens equation for a converging lens.

or

Fig. 23-37 for a converging lens, assumed to be very thin. The right triangles FI'I and FBA (highlighted in yellow) are similar because angle AFB equals angle IFI'; so

$$
\frac{h_i}{h_o} = \frac{d_i - f}{f}
$$

since length $AB = h_0$. Triangles OAO' and IAI' are similar as well. Therefore, h_i d_i

$$
\overline{h_{\rm o}} = \overline{d_{\rm o}}
$$

We equate the right sides of these two equations (the left sides are the same), and divide by d_i to obtain

$$
\frac{1}{f} - \frac{1}{d_i} = \frac{1}{d_o}
$$
\n
$$
\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f}.
$$
\n(23-8)

This is called the **thin lens equation**. It relates the image distance d_i to the object distance d_0 and the focal length f. It is the most useful equation in geometric optics. (Interestingly, it is exactly the same as the mirror equation, Eq. $23-2$). If the object is at infinity, then $1/d_0 = 0$, so $d_i = f$. Thus the focal length is the image distance for an object at infinity, as mentioned earlier.

THIN LENS EQUATION

FIGURE 23-38 Deriving the lens equation for a diverging lens.

CAUTION

diverging lens

Focal length is negative for

We can derive the lens equation for a diverging lens using Fig. 23-38. Triangles IAI' and OAO' are similar; and triangles IFI' and AFB are similar. Thus (noting that length $AB = h_0$)

$$
\frac{h_{\rm i}}{h_{\rm o}} = \frac{d_{\rm i}}{d_{\rm o}} \quad \text{and} \quad \frac{h_{\rm i}}{h_{\rm o}} = \frac{f - d_{\rm i}}{f}.
$$

When we equate the right sides of these two equations and simplify, we obtain

$$
\frac{1}{d_{\rm o}} - \frac{1}{d_{\rm i}} = -\frac{1}{f} \cdot
$$

This equation becomes the same as Eq. 23–8 if we make f and d_i negative. That is, we take f to be *negative for a diverging lens*, and d_i negative when the image is on the same side of the lens as the light comes from. Thus Eq. 23–8 will be valid for both converging and diverging lenses, and for *all* situations, if we use the following sign conventions:

- 1. The focal length is positive for converging lenses and negative for diverging lenses.
- 2. The object distance is positive if the object is on the side of the lens from which the light is coming (this is usually the case, although when lenses are used in combination, it might not be so); otherwise, it is negative.
- 3. The image distance is positive if the image is on the opposite side of the lens from where the light is coming; if it is on the same side, d_i is negative. Equivalently, the image distance is positive for a real image and negative for a virtual image.
- 4. The height of the image, h_i , is positive if the image is upright, and negative if the image is inverted relative to the object. (h_0) is always taken as positive.)

The **magnification**, m , of a lens is defined as the ratio of the image height to object height, $m = h_i/h_o$. From Figs. 23–37 and 23–38 and the conventions just stated (for which we'll need a minus sign below), we have

$$
m = \frac{h_i}{h_o} = -\frac{d_i}{d_o}.
$$
 (23-9)

For an upright image the magnification is positive, and for an inverted image the magnification is negative.

From sign convention 1, it follows that the power (Eq. $23-7$) of a converging lens, in diopters, is positive, whereas the power of a diverging lens is negative. A converging lens is sometimes referred to as a positive lens, and a diverging lens as a negative lens.

PROBLEM SOLVING Thin Lenses

- 1. Draw a ray diagram, as precise as possible, but even a rough one can serve as confirmation of analytic results. Choose one point on the object and draw at least two, preferably three, of the easy-to-draw rays described in Figs. $23-34$ and $23-36$. The image point is where the rays intersect.
- 2. For analytic solutions, solve for unknowns in the

thin lens equation $(Eq. 23-8)$ and the magnification equation (Eq. $23-9$). The thin lens equation involves reciprocals—don't forget to take the reciprocal.

Magnification

of a lens

- 3. Follow the sign conventions above.
- 4. Check that your analytic answers are consistent with your ray diagram.

PROBLEM SOLVING **SIGN CONVENTIONS for lenses**

SECTION 23-8 The Thin Lens Equation; Magnification 651

EXAMPLE 23-9 Image formed by converging lens. What is (a) the position, and (b) the size, of the image of a 7.6-cm-high flower placed 1.00 m from a $+50.0$ -mm-focal-length camera lens?

APPROACH We follow the steps of the Problem Solving Box explicitly. **SOLUTION**

- (1) Ray diagram: Figure $23-39$ is an approximate ray diagram, showing only rays 1 and 3 for a single point on the flower. We see that the image ought to be a little behind the focal point F, to the right of the lens.
- (2) Thin lens and magnification equations: (a) We find the image position analytically using the thin lens equation, Eq. 23–8. The camera lens is converging, with $f = +5.00$ cm, and $d_0 = 100$ cm, and so the thin lens equation gives

$$
\frac{1}{d_i} = \frac{1}{f} - \frac{1}{d_o} = \frac{1}{5.00 \text{ cm}} - \frac{1}{100 \text{ cm}}
$$

$$
= \frac{20.0 - 1.0}{100 \text{ cm}} = \frac{19.0}{100 \text{ cm}}
$$

Then

$$
d_{\rm i} = \frac{100 \text{ cm}}{19.0} = 5.26 \text{ cm},
$$

or 52.6 mm behind the lens. (b) The magnification is

$$
m = -\frac{d_i}{d_o} = -\frac{5.26 \text{ cm}}{100 \text{ cm}} = -0.0526,
$$

SO

$$
h_i = mh_o = (-0.0526)(7.6 \text{ cm}) = -0.40 \text{ cm}.
$$

The image is 4.0 mm high.

- (3) Sign conventions: The image distance d_i came out positive, so the image is behind the lens. The image height is $h_i = -0.40$ cm; the minus sign means the image is inverted.
- (4) Consistency: The analytic results of steps (2) and (3) are consistent with the ray diagram, Fig. 23-39: the image is behind the lens and inverted.

NOTE Part (a) tells us that the image is 2.6 mm farther from the lens than the image for an object at infinity, which equals the focal length, 50.0 mm. Indeed, when focusing a camera lens, the closer the object is to the camera, the farther the lens must be from the film.

EXERCISE G If the flower (object) of Example $23-9$ is moved farther from the lens, does the image move closer to or farther from the lens? (Don't calculate!)

EXAMPLE 23-10 Object close to converging lens. An object is placed 10 cm from a 15-cm-focal-length converging lens. Determine the image position and size (a) analytically, and (b) using a ray diagram.

APPROACH We first use Eqs. 23-8 and 23-9 to obtain an analytic solution, and then confirm with a ray diagram using the special rays 1, 2, and 3 for a single object point.

SOLUTION (a) Given $f = 15$ cm and $d_0 = 10$ cm, then

 $\frac{1}{d_i} = \frac{1}{15 \text{ cm}} - \frac{1}{10 \text{ cm}} = -\frac{1}{30 \text{ cm}},$

and $d_i = -30$ cm. (Remember to take the reciprocal!) Because d_i is negative, the image must be virtual and on the same side of the lens as the object. The magnification

$$
m = -\frac{d_{\rm i}}{d_{\rm o}} = -\frac{-30\,\rm cm}{10\,\rm cm} = 3.0.
$$

The image is three times as large as the object and is upright. This lens is being used as a simple magnifying glass, which we discuss in more detail in Section 25–3. (b) The ray diagram is shown in Fig. 23–40 and confirms the result in part (a) . We choose point O' on the top of the object and draw ray 1, which is easy. But ray 2 may take some thought: if we draw it heading toward F', it is going the wrong way—so we have to draw it as if coming from F' (and so dashed), striking the lens, and then going out parallel to the lens axis. We project it backward with a dashed line, as we must do also for ray 1, in order to find where they cross. Ray 3 is drawn through the lens center, and it crosses the other two rays at the image point, I'.

NOTE From Fig. 23–40 we can see that, whenever an object is placed between a converging lens and its focal point, the image is virtual.

FIGURE 23-40 An object placed within the focal point of a converging lens produces a virtual image. Example 23-10.

EXAMPLE 23-11 Diverging lens. Where must a small insect be placed if a 25-cm-focal-length diverging lens is to form a virtual image 20 cm in front of the lens?

APPROACH The ray diagram is basically that of Fig. 23-38 because our lens here is diverging and our image is in front of the lens within the focal distance. (It would be a valuable exercise to draw the ray diagram to scale, precisely, now.) The insect's distance, d_0 , can be calculated using the thin lens equation. **SOLUTION** The lens is diverging, so f is negative: $f = -25$ cm. The image distance must be negative too because the image is in front of the lens (sign conventions), so $d_i = -20$ cm. Equation 23-8 gives

$$
\frac{1}{d_0} = \frac{1}{f} - \frac{1}{d_1} = -\frac{1}{25 \text{ cm}} + \frac{1}{20 \text{ cm}} = \frac{-4 + 5}{100 \text{ cm}} = \frac{1}{100 \text{ cm}}
$$

So the object must be 100 cm in front of the lens.

EXERCISE H An object is placed 12 cm from a lens with 15-cm focal length. Will the image be real or virtual if the lens is (a) converging or (b) diverging?

EXERCISE I Determine the position of the image produced by a 15.0-cm-focal-length converging lens when an object is placed 13.0 cm in front of it.

Multiple lenses: image formed by first lens is object for second lens

We now consider how to deal with lenses used in combination. When light passes through more than one lens, we find the image formed by the first lens as if it were alone. This image becomes the *object* for the second lens, and we find the image then formed by this second lens, which is the final image if there are only two lenses. The total magnification will be the product of the separate magnifications of each lens, as we shall see. Even if the second lens intercepts the light from the first lens before it forms an image, this technique still works.

EXAMPLE 23-12 A two-lens system. Two converging lenses, A and B, with focal lengths $f_A = 20.0$ cm and $f_B = 25.0$ cm, are placed 80.0 cm apart, as shown in Fig. 23-41a. An object is placed 60.0 cm in front of the first lens as shown in Fig. 23–41b. Determine (a) the position, and (b) the magnification, of the final image formed by the combination of the two lenses.

APPROACH Starting at the tip of our object O, we draw rays 1, 2, and 3 for the first lens, A, and also a ray 4 which, after passing through lens A, acts as "ray 3" (through the center) for the second lens, B. Ray 2 for lens A exits parallel, and so is ray 1 for lens B. To determine the position of the image I_A formed by lens A, we use Eq. 23–8 with $f_A = 20.0$ cm and $d_{OA} = 60.0$ cm. The distance of I_A from lens B is the object distance d_{OB} for lens B. The final image is found using the thin lens equation, this time with all distances relative to lens B. For (b) the magnifications are found from Eq. 23–9 for each lens in turn.

SOLUTION (a) The object is a distance $d_{oA} = +60.0$ cm from the first lens, A, and this lens forms an image whose position can be calculated using the thin lens equation:

$$
\frac{1}{d_{\text{IA}}} = \frac{1}{f_{\text{A}}} - \frac{1}{d_{\text{OA}}} = \frac{1}{20.0 \text{ cm}} - \frac{1}{60.0 \text{ cm}} = \frac{3 - 1}{60.0 \text{ cm}} = \frac{1}{30.0 \text{ cm}}
$$

So the first image I_A is at $d_{iA} = 30.0$ cm behind the first lens. This image becomes the object for the second lens, B. It is a distance d_{OB} = $80.0 \text{ cm} - 30.0 \text{ cm} = 50.0 \text{ cm}$ in front of lens B, as shown in Fig. 23–41b. The image formed by lens B, again using the thin lens equation, is at a distance d_{iB} from the lens B:

$$
\frac{1}{d_{\text{IB}}} = \frac{1}{f_{\text{B}}} - \frac{1}{d_{\text{OB}}} = \frac{1}{25.0 \text{ cm}} - \frac{1}{50.0 \text{ cm}} = \frac{2 - 1}{50.0 \text{ cm}} = \frac{1}{50.0 \text{ cm}}.
$$
\nSince $d_{\text{C}} = 50.0 \text{ cm}$ behind long B. This is the final image, see Fig. 23–411.

Hence
$$
d_{\text{iB}} = 50.0 \text{ cm}
$$
 behind lens B. This is the final image—see Fig. 23–41b.

CAUTION Note that object distance for second lens is not

equal to the image distance for first lens

(b) Lens A has a magnification (Eq. $23-9$)

$$
m_{\rm A} = -\frac{d_{\rm IA}}{d_{\rm OA}} = -\frac{30.0 \text{ cm}}{60.0 \text{ cm}} = -0.500.
$$

Thus, the first image is inverted and is half as high as the object (again Eq. 23–9):

$$
h_{\rm iA} = m_{\rm A} h_{\rm oA} = -0.500 h_{\rm oA}
$$

Lens B takes this image as object and changes its height by a factor

$$
m_{\rm B} = -\frac{d_{\rm iB}}{d_{\rm oB}} = -\frac{50.0 \text{ cm}}{50.0 \text{ cm}} = -1.000.
$$

The second lens reinverts the image (the minus sign) but doesn't change its size. The final image height is (remember h_{OB} is the same as h_{iA})

$$
h_{\text{iR}} = m_{\text{R}} h_{\text{oR}} = m_{\text{R}} h_{\text{iA}} = m_{\text{R}} m_{\text{A}} h_{\text{oA}} = (m_{\text{total}}) h_{\text{oA}}.
$$

The total magnification is the product of m_A and m_B , which here equals m_{total} = $m_A m_B = (-1.000)(-0.500) = +0.500$, or half the original height, and the final image is upright.

Total magnification is $m_{\text{total}} = m_{\text{A}} m_{\text{B}}$

FIGURE 23-42 Determining the focal length of a diverging lens. Example 23-13.

EXAMPLE 23-13 Measuring f for a diverging lens. To measure the focal length of a diverging lens, a converging lens is placed in contact with it, as shown in Fig. 23–42. The Sun's rays are focused by this combination at a point 28.5 cm, behind the lenses as shown. If the converging lens has a focal length f_c of 16.0 cm, what is the focal length f_p of the diverging lens? Assume both lenses are thin and the space between them is negligible.

APPROACH The image distance for the first lens equals its focal length (16.0 cm) since the object distance is infinity (∞). The position of this image, even though it is never actually formed, acts as the object for the second (diverging) lens. We apply the thin lens equation to the diverging lens to find where the final image is.

SOLUTION Rays from the Sun are focused 28.5 cm behind the combination, so the focal length of the total combination is $f_T = 28.5$ cm. If the diverging lens was absent, the converging lens would form the image at its focal point—that is, at a distance $f_c = 16.0 \text{ cm}$ behind it (dashed lines in Fig. 23–42). When the diverging lens is placed next to the converging lens, we treat the image formed by the first lens as the *object* for the second lens. Since this object lies to the right of the diverging lens, this is a situation where d_0 is negative (see the sign conventions, page 651). Thus, for the diverging lens, the object is virtual and $d_0 = -16.0$ cm. The diverging lens forms the image of this virtual object at a distance $d_i = 28.5$ cm away (this was given). Thus,

$$
\frac{1}{f_{\rm D}} = \frac{1}{d_{\rm o}} + \frac{1}{d_{\rm i}} = \frac{1}{-16.0 \text{ cm}} + \frac{1}{28.5 \text{ cm}} = -0.0274 \text{ cm}^{-1}.
$$

We take the reciprocal to find $f_D = -1/(0.0274 \text{ cm}^{-1}) = -36.5 \text{ cm}$.

NOTE If this technique is to work, the converging lens must be "stronger" than the diverging lens—that is, it must have a focal length whose magnitude is less than that of the diverging lens.

23-10 Lensmaker's Equation

A useful equation, known as the lensmaker's equation, relates the focal length of a lens to the radii of curvature R_1 and R_2 of its two surfaces and its index of refraction n :

Lensmaker's equation

$$
\frac{1}{f} = (n-1)\left(\frac{1}{R_1} + \frac{1}{R_2}\right).
$$
 (23-10)

If both surfaces are convex, R_1 and R_2 are considered positive.[†] For a concave surface, the radius must be considered negative.

Notice that Eq. 23–10 is symmetrical in R_1 and R_2 . Thus, if a lens is turned around so that light impinges on the other surface, the focal length is the same even if the two lens surfaces are different.

EXAMPLE 23-14 Calculating f **for a converging lens.** A convex meniscus lens (Figs. 23–29a and 23–43) is made from glass with $n = 1.50$. The radius of curvature of the convex surface is 22.4 cm, and that of the concave surface is 46.2 cm. What is the focal length?

APPROACH We use the lensmaker's equation, Eq. 23-10, to find f .

SOLUTION $R_1 = 22.4$ cm and $R_2 = -46.2$ cm (concave surface). Then

$$
\frac{1}{f} = (1.50 - 1.00) \left(\frac{1}{22.4 \text{ cm}} - \frac{1}{46.2 \text{ cm}} \right) = 0.0115 \text{ cm}^{-1}.
$$

$$
f = \frac{1}{0.0115 \text{ cm}^{-1}} = 87 \text{ cm},
$$

and the lens is converging since $f > 0$.

NOTE If we turn the lens around so that $R_1 = -46.2$ cm and $R_2 = +22.4$ cm, we get the same result.

^{*}Some books use a different convention—for example, R_1 and R_2 are considered positive if their centers of curvature are to the right of the lens, in which case a minus sign replaces the $+$ sign in their equivalent of Eq. 23-10.

Summary

Light appears to travel in straight-line paths, called rays, at a speed v that depends on the **index of refraction**, n , of the material; that is

$$
a = \frac{c}{v},\tag{23-4}
$$

So

where c is the speed of light in vacuum.

When light reflects from a flat surface, the *angle of reflec*tion equals the angle of incidence. This law of reflection explains why mirrors can form images.

In a plane mirror, the image is virtual, upright, the same size as the object, and is as far behind the mirror as the object is in front.

A spherical mirror can be concave or convex. A concave spherical mirror focuses parallel rays of light (light from a very distant object) to a point called the focal point. The distance of this point from the mirror is the **focal length** f of the mirror and

$$
f = \frac{r}{2},\tag{23-1}
$$

where r is the radius of curvature of the mirror.

656 CHAPTER 23 Light: Geometric Optics

Parallel rays falling on a convex mirror reflect from the mirror as if they diverged from a common point behind the mirror. The distance of this point from the mirror is the focal length and is considered negative for a convex mirror.

For a given object, the approximate position and size of the image formed by a mirror can be found by ray tracing. Algebraically, the relation between image and object distances, d_i and d_0 , and the focal length f, is given by the **mirror equation:**

$$
\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f}.
$$
 (23-2)

The ratio of image height h_i to object height h_o , which equals the magnification m of a mirror, is

$$
n = \frac{h_{\rm i}}{h_{\rm o}} = -\frac{d_{\rm i}}{d_{\rm o}}.\tag{23-3}
$$

If the rays that converge to form an image actually pass through the image, so the image would appear on film or a screen placed there, the image is said to be a real image. If the light rays do not actually pass through the image, the image is a virtual image.

FIGURE 23-43 Example 23-14.

When light passes from one transparent medium into another, the rays bend or refract. The law of refraction (Snell's law) states that

$$
n_1 \sin \theta_1 = n_2 \sin \theta_2, \qquad (23-5)
$$

where n_1 and θ_1 are the index of refraction and angle with the normal to the surface for the incident ray, and n_2 and θ_2 are for the refracted ray.

When light rays reach the boundary of a material where the index of refraction decreases, the rays will be totally internally reflected if the incident angle, θ_1 , is such that Snell's law would predict $\sin \theta_2 > 1$. This occurs if θ_1 exceeds the critical angle θ_C given by

$$
\sin \theta_{\rm C} = \frac{n_2}{n_1}.\tag{23-6}
$$

A lens uses refraction to produce a real or virtual image. Parallel rays of light are focused to a point, called the focal point, by a converging lens. The distance of the focal point from the lens is called the **focal length** f of the lens.

After parallel rays pass through a diverging lens, they appear to diverge from a point, its focal point; and the corresponding focal length is considered negative.

Questions

- **1.** What would be the appearance of the Moon if it had (a) a rough surface; (b) a polished mirrorlike surface?
- 2. Archimedes is said to have burned the whole Roman fleet in the harbor of Syracuse by focusing the rays of the Sun with a huge spherical mirror. Is this reasonable?
- 3. Although a plane mirror appears to reverse left and right, it doesn't reverse up and down. Explain.
- 4. If a concave mirror produces a real image, is the image necessarily inverted? Explain.
- 5. An object is placed along the principal axis of a spherical mirror. The magnification of the object is -3.0 . Is the image real or virtual, inverted or upright? Is the mirror concave or convex? On which side of the mirror is the image located?
- 6. Using the rules for the three rays discussed with reference to Fig. 23-13, draw ray 2 for Fig. 23-17b.
- 7. What is the focal length of a plane mirror? What is the magnification of a plane mirror?
- 8. When you look at the Moon's reflection from a ripply sea, it appears elongated (Fig. 23-44). Explain.

FIGURE 23-44 Question 8.

The power P of a lens, which is $P = 1/f$ (Eq. 23-7), is given in diopters, which are units of inverse meters (m^{-1}) .

For a given object, the position and size of the image formed by a lens can be found approximately by ray tracing. Algebraically, the relation between image and object distances, d_i and d_0 , and the focal length f, is given by the **thin lens equation**:

$$
\frac{1}{d_0} + \frac{1}{d_1} = \frac{1}{f}.
$$
 (23-8)

The ratio of image height to object height, which equals the magnification m for a lens, is

$$
m = \frac{h_{\rm i}}{h_{\rm o}} = -\frac{d_{\rm i}}{d_{\rm o}}.\tag{23-9}
$$

When using the various equations of geometrical optics, it is important to remember the sign conventions for all quantities involved: carefully review them (pages 641 and 651) when doing Problems.

[*When two (or more) thin lenses are used in combination to produce an image, the thin lens equation can be used for each lens in sequence. The image produced by the first lens acts as the object for the second lens. The lensmaker's equation relates the radii of curvature of the lens surfaces and the lens' index of refraction to the focal length of the lens.]

- 9. What is the angle of refraction when a light ray meets the boundary between two materials perpendicularly?
- 10. How might you determine the speed of light in a solid, rectangular, transparent object?
- 11. When you look down into a swimming pool or a lake, are you likely to underestimate or overestimate its depth? Explain. How does the apparent depth vary with the viewing angle? (Use ray diagrams.)
- 12. Draw a ray diagram to show why a stick looks bent when part of it is under water (Fig. 23-21).
- 13. Your eye looks into an aquarium and views a fish inside. One ray of light that emerges from the tank is shown in Fig. 23-45, as well as the apparent position of the fish. In the drawing, indicate the approximate position of the actual fish. Briefly justify your answer.

FIGURE 23-45 Ouestion 13.

- 14. How can you "see" a round drop of water on a table even though the water is transparent and colorless?
- 15. When you look up at an object in air from beneath the surface in a swimming pool, does the object appear to be the same size as when you see it directly in air? Explain.
- 16. How can a spherical mirror have a negative object distance?
- 17. Light rays from stars (including our Sun) always bend toward the vertical direction as they pass through the Earth's atmosphere. (a) Why does this make sense? (b) What can you conclude about the apparent positions of stars as viewed from Earth?
- 18. Where must the film be placed if a camera lens is to make a sharp image of an object very far away?
- 19. What type of mirror is shown in Fig. 23–46? Explain.

FIGURE 23-46 Ouestion 19.

- 20. A photographer moves closer to his subject and then refocuses. Does the camera lens move farther from or closer to the film? Explain.
- 21. Can a diverging lens form a real image under any circumstances? Explain.
- 22. Use ray diagrams to show that a real image formed by a thin lens is always inverted, whereas a virtual image is always upright if the object is real.
- 23. Light rays are said to be "reversible." Is this consistent with the thin lens equation? Explain.
- 24. Can real images be projected on a screen? Can virtual images? Can either be photographed? Discuss carefully.
- 25. A thin converging lens is moved closer to a nearby object. Does the real image formed change (a) in position, (b) in size? If yes, describe how.
- 26. A lens is made of a material with an index of refraction $n = 1.30$. In air, it is a converging lens. Will it still be a converging lens if placed in water? Explain, using a ray diagram.
- 27. A dog with its tail in the air stands facing a converging lens. If the nose and the tail are each focused on a screen in turn, which will have the greater magnification?
- 28. A cat with its tail in the air stands facing a converging lens. Under what circumstances (if any) would the image of the nose be virtual and the image of the tail be real? Where would the image of the rest of the cat be?
- * 29. Why, in Example 23–13, must the converging lens have a shorter focal length than the diverging lens if the latter's focal length is to be determined by combining them?
- * 30. Explain how you could have a virtual object.
- *31. An unsymmetrical lens (say, planoconvex) forms an image of a nearby object. Does the image point change if the lens is turned around?
- *32. The thicker a double convex lens is in the center as compared to its edges, the shorter its focal length for a given lens diameter. Explain.
- *33. Consider two converging lenses separated by some distance. An object is placed so that the image from the first lens lies exactly at the focal point of the second lens. Will this combination produce an image? If so, where? If not, why not?

Problems

23-2 Reflection; Plane Mirrors

- 1. (I) Suppose that you want to take a photograph of yourself as you look at your image in a flat mirror 2.5 m away. For what distance should the camera lens be focused?
- 2. (I) When you look at yourself in a 60-cm-tall plane mirror, you see the same amount of your body whether you are close to the mirror or far away. (Try it and see.) Use ray diagrams to show why this should be true.
- 3. (II) Two mirrors meet at a 135° angle, Fig. 23-47. If light rays strike one mirror at 40 $^{\circ}$ as shown, at what angle ϕ do they leave the second mirror?

4. (II) A person whose eyes are 1.68 m above the floor stands 2.20 m in front of a vertical plane mirror whose bottom edge is 43 cm above the floor, Fig. 23-48. What is the horizontal distance x to the base of the wall supporting the mirror of the nearest point on the floor that can be seen reflected in the mirror?

FIGURE 23-48 Problem 4.
- 5. (II) Suppose you are 90 cm from a plane mirror. What area of the mirror is used to reflect the rays entering one eye from a point on the tip of your nose if your pupil diameter is 5.5 mm?
- 6. (III) Show that if two plane mirrors meet at an angle ϕ , a single ray reflected successively from both mirrors is deflected through an angle of 2ϕ independent of the incident angle. Assume ϕ < 90° and that only two reflections, one from each mirror, take place.

23-3 Spherical Mirrors

- 7. (I) A solar cooker, really a concave mirror pointed at the Sun, focuses the Sun's rays 18.0 cm in front of the mirror. What is the radius of the spherical surface from which the mirror was made?
- 8. (I) How far from a concave mirror (radius 23.0 cm) must an object be placed if its image is to be at infinity?
- 9. (II) If you look at yourself in a shiny Christmas tree ball with a diameter of 9.0 cm when your face is 30.0 cm away from it, where is your image? Is it real or virtual? Is it upright or inverted?
- 10. (II) A mirror at an amusement park shows an upright image of any person who stands 1.4 m in front of it. If the image is three times the person's height, what is the radius of curvature?
- 11. (II) A dentist wants a small mirror that, when 2.20 cm from a tooth, will produce a $4.5 \times$ upright image. What kind of mirror must be used and what must its radius of curvature be?
- 12. (II) Some rearview mirrors produce images of cars behind you that are smaller than they would be if the mirror were flat. Are the mirrors concave or convex? What is a mirror's radius of curvature if cars 20.0 m away appear $0.33\times$ their normal size?
- 13. (II) A luminous object 3.0 mm high is placed 20.0 cm from a convex mirror of radius of curvature 20.0 cm. (a) Show by ray tracing that the image is virtual, and estimate the image distance. (b) Show that the (negative) image distance can be computed from Eq. 23-2 using a focal length of -10.0 cm. (c) Compute the image size, using Eq. $23-3$.
- **14.** (II) You are standing 3.0 m from a convex security mirror in a store. You estimate the height of your image to be half of your actual height. Estimate the radius of curvature of the mirror.
- **15.** (II) (a) Where should an object be placed in front of a concave mirror so that it produces an image at the same location as the object? (b) Is the image real or virtual? (c) Is the image inverted or upright? (d) What is the magnification of the image?
- 16. (II) The image of a distant tree is virtual and very small when viewed in a curved mirror. The image appears to be 18.0 cm behind the mirror. What kind of mirror is it, and what is its radius of curvature?
- 17. (II) Use two different techniques, (a) a ray diagram, and (b) the mirror equation, to show that the magnitude of the magnification of a concave mirror is less than 1 if the object is beyond the center of curvature $C(d_0 > r)$, and is greater than 1 if the object is within $C(d_0 < r)$.
- 18. (II) Show, using a ray diagram, that the magnification m of a convex mirror is $m = -d_i/d_o$, just as for a concave mirror. [Hint: consider a ray from the top of the object that reflects at the center of the mirror.]
- 19. (II) Use ray diagrams to show that the mirror equation, Eq. 23-2, is valid for a convex mirror as long as f is considered negative.
- **20.** (II) The magnification of a convex mirror is $+0.65 \times$ for objects 2.2 m from the mirror. What is the focal length of this mirror?
- 21. (III) A 4.5-cm-tall object is placed 28 cm in front of a spherical mirror. It is desired to produce a virtual image that is upright and 3.5 cm tall. (a) What type of mirror should be used? (b) Where is the image located? (c) What is the focal length of the mirror? (d) What is the radius of curvature of the mirror?
- 22. (III) A shaving/makeup mirror is designed to magnify your face by a factor of 1.33 when your face is placed 20.0 cm in front of it. (a) What type of mirror is it? (b) Describe the type of image that it makes of your face. (c) Calculate the required radius of curvature for the mirror.

23-4 Index of Refraction

- 23. (I) What is the speed of light in (a) crown glass, (b) Lucite, and (c) ethyl alcohol?
- **24.** (I) The speed of light in ice is 2.29×10^8 m/s. What is the index of refraction of ice?
- 25. (II) The speed of light in a certain substance is 89% of its value in water. What is the index of refraction of this substance?

23-5 Refraction: Snell's Law

- 26. (I) A flashlight beam strikes the surface of a pane of glass $(n = 1.58)$ at a 63° angle to the normal. What is the angle of refraction?
- 27. (I) A diver shines a flashlight upward from beneath the water at a 42.5° angle to the vertical. At what angle does the light leave the water?
- 28. (I) A light beam coming from an underwater spotlight exits the water at an angle of 66.0° to the vertical. At what angle of incidence does it hit the air-water interface from below the surface?
- 29. (I) Rays of the Sun are seen to make a 31.0° angle to the vertical beneath the water. At what angle above the horizon is the Sun?
- 30. (II) An aquarium filled with water has flat glass sides whose index of refraction is 1.52. A beam of light from outside the aquarium strikes the glass at a 43.5° angle to the perpendicular (Fig. 23–49). What is the angle of this light ray when it enters (a) the glass, and then (b) the water? (c) What would be the refracted angle if the ray entered the water directly?

31. (II) In searching the bottom of a pool at night, a watchman shines a narrow beam of light from his flashlight, 1.3 m above the water level, onto the surface of the water at a point 2.7 m from the edge of the pool (Fig. 23–50). Where does the spot of light hit the bottom of the pool, measured from the wall beneath his foot, if the pool is 2.1 m deep?

FIGURE 23-50 Problem 31.

32. (II) Light is incident on an equilateral glass prism at a 45.0° angle to one face, Fig. 23–51. Calculate the angle at which light emerges from the opposite face. Assume that $n = 1.58$.

FIGURE 23-51 Problems 32 and 40.

- 33. (II) A beam of light in air strikes a slab of glass $(n = 1.52)$ and is partially reflected and partially refracted. Find the angle of incidence if the angle of reflection is twice the angle of refraction.
- 34. (III) Prove in general that for a light beam incident on a uniform layer of transparent material, as in Fig. 23-22, the direction of the emerging beam is parallel to the incident beam, independent of the incident angle θ . Assume air on both sides of the glass.
- 35. (III) A light ray is incident on a flat piece of glass with index of refraction n as in Fig. 23–22. Show that if the incident angle θ is small, the emerging ray is displaced a distance $d = t\theta(n - 1)/n$ from the incident ray, where t is the thickness of the glass and θ is in radians. [*Hint*: for small θ , sin $\theta \approx \tan \theta \approx \theta$ in radians.]

23-6 Total Internal Reflection

36. (I) What is the critical angle for the interface between water and Lucite? To be totally internally reflected, the light must start in which material?

- 37. (I) The critical angle for a certain liquid-air surface is 47.7°. What is the index of refraction of the liquid?
- 38. (II) A beam of light is emitted in a pool of water from a depth of 62.0 cm. Where must it strike the air-water interface, relative to the spot directly above it, in order that the light does not exit the water?
- 39. (II) A beam of light is emitted 8.0 cm beneath the surface of a liquid and strikes the surface 7.0 cm from the point directly above the source. If total internal reflection occurs, what can you say about the index of refraction of the liquid?
- 40. (III) Suppose a ray strikes the left face of the prism in Fig. $23-51$ at 45.0° as shown, but is totally internally reflected at the opposite side. If the prism apex angle (at the top) is $\phi = 75.0^{\circ}$, what can you say about the index of refraction of the prism?
- 41. (III) A beam of light enters the end of an optic fiber as shown in Fig. 23-52. Show that we can guarantee total internal reflection at the side surface of the material (at point a), if the index of refraction is greater than about 1.42. In other words, regardless of the angle α , the light beam reflects back into the material at point a.

 $42.$ (III) (*a*) What is the minimum index of refraction for a glass or plastic prism to be used in binoculars (Fig. 23–26) so that total internal reflection occurs at 45° ? (b) Will binoculars work if its prisms (assume $n = 1.50$) are immersed in water? (c) What minimum n is needed if the prisms are immersed in water?

23-7 and 23-8 Thin Lenses

- 43. (I) A sharp image is located 78.0 mm behind a 65.0-mmfocal-length converging lens. Find the object distance (a) using a ray diagram, (b) by calculation.
- 44. (I) Sunlight is observed to focus at a point 18.5 cm behind a lens. (a) What kind of lens is it? (b) What is its power in diopters?
- 45. (I) A certain lens focuses light from an object 2.75 m away as an image 48.3 cm on the other side of the lens. What type of lens is it and what is its focal length? Is the image real or virtual?
- **46.** (I) (a) What is the power of a 20.5-cm-focal-length lens? (b) What is the focal length of a -6.25 -diopter lens? (c) Are these lenses converging or diverging?
- 47. (II) A stamp collector uses a converging lens with focal length 24 cm to view a stamp 18 cm in front of the lens. (a) Where is the image located? (b) What is the magnification?
- 48. (II) A -5.5 -D lens is held 14.0 cm from an object 4.0 mm high. What are the position, type, and height of the image?
- 49. (II) An 80-mm-focal-length lens is used to focus an image on the film of a camera. The maximum distance allowed between the lens and the film plane is 120 mm. (a) How far ahead of the film should the lens be if the object to be photographed is 10.0 m away? (b) 3.0 m away? (c) 1.0 m away? (d) What is the closest object this lens could photograph sharply?
- 50. (II) It is desired to magnify reading material by a factor of $2.5 \times$ when a book is placed 8.0 cm behind a lens. (a) Draw a ray diagram and describe the type of image this would be. (b) What type of lens is needed? (c) What is the power of the lens in diopters?
- 51. (II) An object is located 1.5 m from an 8.0-D lens. By how much does the image move if the object is moved (a) 1.0 m closer to the lens, and (b) 1.0 m farther from the lens?
- 52. (II) How far from a converging lens with a focal length of 25 cm should an object be placed to produce a real image which is the same size as the object?
- 53. (II) (a) How far from a 50.0-mm-focal-length lens must an object be placed if its image is to be magnified $2.00 \times$ and be real? (b) What if the image is to be virtual and magnified $2.00 \times ?$
- 54. (II) Repeat Problem 53 for a -50.0 -mm-focal-length lens. [Hint: consider objects real or virtual (formed by some other piece of optics).]
- 55. (II) (a) A 2.00-cm-high insect is 1.20 m from a 135-mmfocal-length lens. Where is the image, how high is it, and what type is it? (b) What if $f = -135$ mm?
- 56. (III) How far apart are an object and an image formed by a 75-cm-focal-length converging lens if the image is $2.5 \times$ larger than the object and is real?
- 57. (III) A bright object and a viewing screen are separated by a distance of 66.0 cm. At what location(s) between the object and the screen should a lens of focal length 12.5 cm be placed in order to produce a crisp image on the screen? [*Hint*: first draw a diagram.]

* 23-9 Lens Combinations

- *58. (II) Two 28.0-cm-focal-length converging lenses are placed 16.5 cm apart. An object is placed 36.0 cm in front of one lens. Where will the final image formed by the second lens be located? What is the total magnification?
- *59. (II) A diverging lens with $f = -31.5$ cm is placed 14.0 cm behind a converging lens with $f = 20.0$ cm. Where will an object at infinity be focused?
- $*60.$ (II) A 31.0-cm-focal-length converging lens is 21.0 cm behind a diverging lens. Parallel light strikes the diverging lens. After passing through the converging lens, the light is again parallel. What is the focal length of the diverging lens? [Hint: first draw a ray diagram.]
- * 61. (II) The two converging lenses of Example 23–12 are now placed only 20.0 cm apart. The object is still 60.0 cm in front of the first lens as in Fig. 23-41. In this case, determine (a) the position of the final image, and (b) the overall magnification. (c) Sketch the ray diagram for this system.
- * 62. (II) Two converging lenses are placed 30.0 cm apart. The focal length of the lens on the right is 20.0 cm, and the focal length of the lens on the left is 15.0 cm. An object is placed to the left of the 15.0-cm-focal-length lens. A final image from both lenses is inverted and located halfway between the two lenses. How far to the left of the 15.0-cm-focal-length lens is the original object?
- $*$ 63. (II) A diverging lens with a focal length of -14 cm is placed 12 cm to the right of a converging lens with a focal length of 18 cm. An object is placed 33 cm to the left of the converging lens. (a) Where will the final image be located? (b) Where will the image be if the diverging lens is 38 cm from the converging lens?
- *64. (II) Two lenses, one converging with focal length 20.0 cm and one diverging with focal length -10.0 cm, are placed 25.0 cm apart. An object is placed 60.0 cm in front of the converging lens. Determine (a) the position and (b) the magnification of the final image formed. (c) Sketch a ray diagram for this system.
- * 65. (III) A diverging lens is placed next to a converging lens of focal length f_c , as in Fig. 23-42. If f_T represents the focal length of the combination, show that the focal length of the diverging lens, f_D , is given by

$$
\frac{1}{f_{\rm D}}=\frac{1}{f_{\rm T}}-\frac{1}{f_{\rm C}}
$$

* 23-10 Lensmaker's Equation

- * 66. (I) A double concave lens has surface radii of 34.2 cm and 23.8 cm. What is the focal length if $n = 1.52$?
- * 67. (I) Both surfaces of a double convex lens have radii of 31.0 cm. If the focal length is 28.9 cm, what is the index of refraction of the lens material?
- * 68. (II) A planoconcave lens ($n = 1.50$) has a focal length of -23.4 cm. What is the radius of the concave surface?
- * 69. (II) A Lucite planoconcave lens (see Fig. 23–29b) has one flat surface and the other has $R = -18.4$ cm. What is the focal length?
- * 70. (II) A symmetric double convex lens with a focal length of 25.0 cm is to be made from glass with an index of refraction of 1.52. What should be the radius of curvature for each surface?
- $*71.$ (II) A prescription for a corrective lens calls for $+1.50$ D. The lensmaker grinds the lens from a "blank" with $n = 1.56$ and a preformed convex front surface of radius of curvature of 40.0 cm. What should be the radius of curvature of the other surface?

General Problems

 72 . Two plane mirrors face each other 2.0 m apart as in Fig. 23-53. You stand 1.5 m away from one of these mirrors and look into it. You will see multiple images of yourself. (a) How far away from you are the first three images in the mirror in front of you? (b) Are these first three images facing toward you or away from you?

73. We wish to determine the depth of a swimming pool filled with water. We measure the width $(x = 5.50 \text{ m})$ and then note that the bottom edge of the pool is just visible at an angle of 14.0° above the horizontal as shown in Fig. 23–54. Calculate the depth of the pool.

- 74. The critical angle of a certain piece of plastic in air is $\theta_C = 37.3^{\circ}$. What is the critical angle of the same plastic if it is immersed in water?
- 75. (a) A plane mirror can be considered a limiting case of a spherical mirror. Specify what this limit is. (b) Determine an equation that relates the image and object distances in this limit of a plane mirror. (c) Determine the magnification of a plane mirror in this same limit. (d) Are your results in parts (b) and (c) consistent with the discussion of Section 23-2 on plane mirrors?
- 76. Stand up two plane mirrors so they form a 90° angle as in Fig. 23-55. When you look into this double mirror, you see yourself as others see you, instead of reversed as in a single mirror. Make a careful ray diagram to show how this occurs.

FIGURE 23-55 Problem 76.

- 77. Show analytically that a diverging lens can never form a real image of a real object. Can you describe a situation in which a diverging lens can form a real image?
- Each student in a physics lab is assigned to find the loca-78. tion where a bright object may be placed in order that a concave mirror with radius of curvature $r = 40$ cm will produce an image three times the size of the object. Two students complete the assignment at different times using identical equipment, but when they compare notes later, they discover that their answers for the object distance are not the same. Explain why they do not necessarily need to repeat the lab, and justify your response with a calculation.
- 79. If the apex angle of a prism is $\phi = 72^{\circ}$ (see Fig. 23–56), what is the minimum incident angle for a ray if it is to emerge from the opposite side (i.e., not be totally internally reflected), given $n = 1.50$?

FIGURE 23-56 Problem 79.

- 80. The end faces of a cylindrical glass rod ($n = 1.54$) are perpendicular to the sides. Show that a light ray entering an end face at any angle will be totally internally reflected inside the rod when the ray strikes the sides. Assume the rod is in air. What if it were in water?
- *81. A lighted candle is placed 33 cm in front of a converging lens of focal length $f_1 = 15$ cm, which in turn is 55 cm in front of another converging lens of focal length $f_2 = 12$ cm (see Fig. 23-57). (a) Draw a ray diagram and estimate the location and the relative size of the final image. (b) Calculate the position and relative size of the final image.

FIGURE 23-57 Problem 81.

- 82. A bright object is placed on one side of a converging lens of focal length f , and a white screen for viewing the image is on the opposite side. The distance $d_{\rm T} = d_{\rm i} + d_{\rm o}$ between the object and the screen is kept fixed, but the lens can be moved. (a) Show that if $d_T > 4f$, there will be two positions where the lens can be placed and a sharp image will be produced on the screen. (b) If $d_T < 4f$, show that there will be no lens position where a sharp image is formed. (c) Determine a formula for the distance between the two lens positions in part (a) , and the ratio of the image sizes.
- 662 CHAPTER 23 Light: Geometric Optics

83. In a slide or movie projector, the film acts as the object whose image is projected on a screen (Fig. 23-58). If a 105-mm-focal-length lens is to project an image on a screen 8.00 m away, how far from the lens should the slide be? If the slide is 36 mm wide, how wide will the picture be on the screen?

FIGURE 23-58 Problem 83.

- 84. A 35-mm slide (picture size is actually 24 by 36 mm) is to be projected on a screen 1.80 m by 2.70 m placed 7.50 m from the projector. What focal-length lens should be used if the image is to cover the screen?
- 85. Show analytically that the image formed by a converging lens is real and inverted if the object is beyond the focal point $(d_0 > f)$, and is virtual and upright if the object is within the focal point $(d_0 < f)$. Describe the image if the object is itself an image, formed by another lens, so its position is beyond the lens, for which $-d_0 > f$, and for which $0 < -d_0 < f$.
- 86. A movie star catches a reporter shooting pictures of her at home. She claims the reporter was trespassing. To prove her point, she gives as evidence the film she seized. Her 1.75-m height is 8.25 mm high on the film, and the focal length of the camera lens was 210mm. How far away from the subject was the reporter standing?
- 87. How large is the image of the Sun on film used in a camera with (a) a 28-mm-focal-length lens, (b) a 50-mmfocal-length lens, and (c) a 135-mm-focal-length lens? (d) If the 50-mm lens is considered normal for this camera, what relative magnification does each of the other two lenses provide? The Sun has diameter 1.4×10^6 km, and it is 1.5×10^8 km away.
- 88. (a) An object 34.5 cm in front of a certain lens is imaged 8.20 cm in front of that lens (on the same side as the object). What type of lens is this, and what is its focal length? Is the image real or virtual? (b) If the image were located, instead, 41.5 cm in front of the lens, what type of lens would it be and what focal length would it have?
- 89. When an object is placed 60.0 cm from a certain converging lens, it forms a real image. When the object is moved to 40.0 cm from the lens, the image moves 10.0 cm farther from the lens. Find the focal length of this lens.
- 90. A small object is 25.0 cm from a diverging lens as shown in Fig. 23-59. A converging lens with a focal length of 12.0 cm is 30.0 cm to the right of the diverging lens. The two-lens system forms a real inverted image 17.0 cm to the right of the converging lens. What is the focal length of the diverging lens?

FIGURE 23-59 Problem 90.

- 91. An object is placed 15 cm from a certain mirror. The image is half the size of the object, inverted, and real. How far is the image from the mirror, and what is the radius of curvature of the mirror?
- 92. (a) Show that the lens equation can be written in the Newtonian form

 $xx' = f^2$.

where x is the distance of the object from the focal point on the front side of the lens, and x' is the distance of the image to the focal point on the other side of the lens. Calculate the location of an image if the object is placed 45.0 cm in front of a convex lens with a focal length f of 32.0 cm using (b) the standard form of the thin lens equation, and (c) the Newtonian form, stated above.

- $*93.$ A converging lens with focal length of 10.0 cm is placed in contact with a diverging lens with a focal length of -20.0 cm. What is the focal length of the combination, and is the combination converging or diverging?
- * 94. (a) Show that if two thin lenses of focal lengths f_1 and f_2 are placed in contact with each other, the focal length of the combination is given by $f_T = f_1 f_2/(f_1 + f_2)$. (b) Show that the power P of the combination of two lenses is the sum of their separate powers, $P = P_1 + P_2$.

Answers to Exercises

- $A: No.$
- **B:** Yes; for a plane mirror, $r = \infty$, so $f = \infty$; then Eq. 23–2 gives $1/d_0 + 1/d_i = 0$, or $d_i = -d_0$.
- C: Toward.
- D: None.
- $E: 1.414.$
- **F:** No total internal reflection, $\theta_C > 45^\circ$.
- G: Closer to it.
- $H: (a)$ Virtual; (b) virtual.
- $\textbf{I}: -97.5 \text{ cm}$ (that is, 97.5 cm in front of lens).

The beautiful colors from the surface of this soap bubble can be nicely explained by the wave theory of light. A soap bubble is a very thin spherical film filled with air; light reflected from the outer and inner surfaces of this thin film of soapy water interferes constructively to produce the bright colors. Which color we see at any point depends on the thickness of the soapy water film at that point and also on the viewing angle.

We cover fundamental aspects of the wave nature of light, including interference and diffraction, thin-film interference, and polarization. We also cover many applications, from spectrometry to LCD monitor screens.

CHAPTER

The Wave Nature of Light

I hat light carries energy is obvious to anyone who has focused the Sun's rays with a magnifying glass on a piece of paper and burned a hole in it. But how does light travel, and in what form is this energy carried? In our discussion of waves in Chapter 11, we noted that energy can be carried from place to place in basically two ways: by particles or by waves. In the first case, material objects or particles can carry energy, such as an avalanche or rushing water. In the second case, water waves and sound waves, for example, can carry energy over long distances even though the oscillating particles of the medium do not travel these distances. In view of this, what can we say about the nature of light: does light travel as a stream of particles away from its source, or does light travel in the form of waves that spread outward from the source?

Historically, this question has turned out to be a difficult one. For one thing, light does not reveal itself in any obvious way as being made up of tiny particles; nor do we see tiny light waves passing by as we do water waves. The evidence seemed to favor first one side and then the other until about 1830, when most physicists had accepted the wave theory. By the end of the nineteenth century, light was considered to be an *electromagnetic wave* (Chapter 22). In the early twentieth century, light was shown to have a particle nature as well, as we shall discuss in Chapter 27. Nonetheless, the wave theory of light remains valid and has proved very successful. We now investigate the evidence for the wave theory and how it has been used to explain a wide range of phenomena.

Waves Versus Particles: 24-1 **Huygens' Principle and Diffraction**

The Dutch scientist Christian Huygens (1629-1695), a contemporary of Newton, proposed a wave theory of light that had much merit. Still useful today is a technique Huygens developed for predicting the future position of a wave front when an earlier position is known. By a wave front, we mean all the points along a twoor three-dimensional wave that form a wave crest-what we simply call a "wave" as seen on the ocean. Wave fronts are perpendicular to rays as we discussed in Chapter 11 (Fig. 11-34). **Huygens' principle** can be stated as follows: *Every* point on a wave front can be considered as a source of tiny wavelets that spread out in the forward direction at the speed of the wave itself. The new wave front is the envelope of all the wavelets—that is, the tangent to all of them.

As a simple example of the use of Huygens' principle, consider the wave front AB in Fig. 24–1, which is traveling away from a source S. We assume the medium is *isotropic*—that is, the speed v of the waves is the same in all directions. To find the wave front a short time t after it is at AB, tiny circles are drawn with radius $r = vt$. The centers of these tiny circles are blue dots on the original wave front AB, and the circles represent Huygens' (imaginary) wavelets. The tangent to all these wavelets, the curved line CD, is the new position of the wave front.

Huygens' principle is particularly useful for analyzing what happens when waves impinge on an obstacle and the wave fronts are partially interrupted. Huygens' principle predicts that waves bend in behind an obstacle, as shown in Fig. $24-2$. This is just what water waves do, as we saw in Chapter 11 (Figs. 11–44) and $11-45$). The bending of waves behind obstacles into the "shadow region" is known as **diffraction**. Since diffraction occurs for waves, but not for particles, it can serve as one means for distinguishing the nature of light.

FIGURE 24-1 Huygens' principle, used to determine wave front CD when wave front AB is given.

FIGURE 24-2 Huygens' principle is consistent with diffraction (a) around the edge of an obstacle, (b) through a large hole, (c) through a small hole whose size is on the order of the wavelength of the wave.

Does light exhibit diffraction? In the mid-seventeenth century, the Jesuit priest Francesco Grimaldi (1618-1663) had observed that when sunlight entered a darkened room through a tiny hole in a screen, the spot on the opposite wall was larger than would be expected from geometric rays. He also observed that the border of the image was not clear but was surrounded by colored fringes. Grimaldi attributed this to the diffraction of light.

The wave model of light nicely accounts for diffraction. But the ray model (Chapter 23) cannot account for diffraction, and it is important to be aware of such limitations to the ray model. Geometric optics using rays is successful in a wide range of situations only because normal openings and obstacles are much larger than the wavelength of the light, and so relatively little diffraction or bending occurs.

-2 Huygens' Principle and the Law of Refraction 24

The laws of reflection and refraction were well known in Newton's time. The law of reflection could not distinguish between the two theories we just discussed: waves versus particles. For when waves reflect from an obstacle, the angle of incidence equals the angle of reflection (Fig. $11-35$). The same is true of particles—think of a tennis ball without spin striking a flat surface.

The law of refraction is another matter. Consider a ray of light entering a medium where it is bent toward the normal, as when traveling from air into water. As shown in Fig. 24–3, this bending can be constructed using Huygens' principle if we

FIGURE 24-3 Refraction explained, using Huygens' principle. Wave fronts are perpendicular to the rays.

assume the speed of light is less in the second medium $(v_2 < v_1)$. In time t, point B on wave front AB (perpendicular to the incoming ray) travels a distance $v_1 t$ to reach point D. Point A on the wave front, traveling in the second medium, goes a distance v_2t to reach point C, and $v_2t \le v_1t$. Huygens' principle is applied to points A and B to obtain the curved wavelets shown at C and D. The wave front is tangent to these two wavelets, so the new wave front is the line CD. Hence the rays, which are perpendicular to the wave fronts, bend toward the normal if $v_2 < v_1$, as drawn. (This is basically the same discussion we used around Fig. $11-43$).

Newton favored a particle theory of light which predicted the opposite result, that the speed of light would be greater in the second medium $(v_2 > v_1)$. Thus the wave theory predicts that the speed of light in water, for example, is less than in air; and Newton's particle theory predicts the reverse. An experiment to actually measure the speed of light in water was performed in 1850 by the French physicist Jean Foucault, and it confirmed the wave-theory prediction. By then, however, the wave theory was already fully accepted, as we shall see in the next Section.

Snell's law of refraction follows directly from Huygens' principle, given that the speed of light v in any medium is related to the speed in a vacuum, c , and the index of refraction, *n*, by Eq. 23–4: that is, $v = c/n$. From the Huygens' construction of Fig. 24–3, angle ADC is equal to θ_2 and angle BAD is equal to θ_1 . Then for the two triangles that have the common side AD, we have

$$
\sin \theta_1 = \frac{v_1 t}{AD}, \qquad \sin \theta_2 = \frac{v_2 t}{AD}
$$

We divide these two equations and obtain

$$
\frac{\sin \theta_1}{\sin \theta_2} = \frac{v_1}{v_2}.
$$

Then, since $v_1 = c/n_1$ and $v_2 = c/n_2$,

$$
n_1\sin\theta_1 = n_2\sin\theta_2,
$$

which is Snell's law of refraction, Eq. 23-5. (The law of reflection can be derived from Huygens' principle in a similar way.)

When a light wave travels from one medium to another, its frequency does not change, but its wavelength does. This can be seen from Fig. 24–3, where each of the blue lines representing a wave front corresponds to a crest (peak) of the wave. Then

$$
\frac{\lambda_2}{\lambda_1} = \frac{v_2 t}{v_1 t} = \frac{v_2}{v_1} = \frac{n_1}{n_2},
$$

where, in the last step, we used Eq. 23-4, $v = c/n$. If medium 1 is a vacuum (or air), so $n_1 = 1$, $v_1 = c$, and we call λ_1 simply λ , then the wavelength in another medium of index of refraction $n (= n_2)$ will be

$$
\lambda_n = \frac{\lambda}{n}.\tag{24-1}
$$

This result is consistent with the frequency f being unchanged no matter what medium the wave is traveling in, since $c = f\lambda$.

Wave fronts can be used to explain how mirages are produced by refraction of light. For example, on a hot day motorists sometimes see a mirage of water on the highway ahead of them, with distant vehicles seemingly reflected in it (Fig. 24–4a). On a hot day, there can be a layer of very hot air next to the roadway (made hot by the Sun beating on the road). Hot air is less dense than cooler air, so the index of refraction is slightly lower in the hot air. In Fig. 24-4b, we see a diagram of light coming from one point on a distant car (on the right) heading left toward the observer. Wave fronts and two rays are shown. Ray A heads directly at the observer and follows a straight-line path, and represents the normal view of the distant car. Ray B is a ray initially directed slightly downward, but it bends slightly as it moves through layers of air of different index of refraction. The wave fronts, shown in blue in Fig. 24-4b, move slightly faster in the layers of air nearer the ground (as in Fig. 24–3, and also the soldier analogy in Fig. $11-43$). Thus ray B is bent as shown, and seems to the observer to be coming from below (dashed line) as if reflected off the road. Hence the mirage.

FIGURE 24-4 (a) A highway mirage. (b) Drawing (greatly exaggerated) showing wave fronts and rays to explain highway mirages. Note how sections of the wave fronts near the ground move faster and so are farther apart.

Direct ray Ray directed slightly downward Observer \overline{B} Ray B seems to come from here (a)

lines are observed.

24-3 Interference-Young's Double-Slit Experiment

In 1801, the Englishman Thomas Young (1773–1829) obtained convincing evidence for the wave nature of light and was even able to measure wavelengths for visible light. Figure 24–5a shows a schematic diagram of Young's famous double-slit experiment. Light from a single source (Young used the Sun) falls on a screen containing two closely spaced slits S_1 and S_2 . If light consists of tiny particles, we might expect to see two bright lines on a screen placed behind the slits as in (b). But instead a series of bright lines are seen, as in (c). Young was able to explain this result as a wave-interference phenomenon. To see this, imagine plane waves of light of a single wavelength—called **monochromatic**, meaning "one color"—falling on the two slits as shown in Fig. 24–6. Because of diffraction, the waves leaving the two small slits spread out as shown. This is equivalent to the interference pattern produced when two rocks are thrown into a lake (Fig. 11-37), or when sound from two loudspeakers interferes (Fig. 12-16). Recall Section 11-12 on wave interference.

FIGURE 24-6 If light is a wave, light passing through one of two slits should interfere with light passing through the other slit.

To see how an interference pattern is produced on the screen, we make use of Fig. 24–7. Waves of wavelength λ are shown entering the slits S₁ and S₂, which are a distance d apart. The waves spread out in all directions after passing through the slits, but they are shown only for three different angles θ . In Fig. 24–7a, the waves reaching the center of the screen are shown ($\theta = 0^{\circ}$). The waves from the two slits travel the same distance, so they are in phase: a crest of one wave arrives at the same time as a crest of the other wave. Hence the amplitudes of the two waves add to form a larger amplitude as shown in Fig. 24–8a. This is **constructive interference**, and there is a bright area at the center of the screen. Constructive interference also occurs when the paths of the two rays differ by one wavelength (or any whole number of wavelengths), as shown in Fig. 24-7b; also here there will be brightness on the screen. But if one ray travels an extra distance of one-half wavelength (or $\frac{3}{2}\lambda$, $\frac{5}{2}\lambda$, and so on), the two waves are exactly out of phase when they reach the screen: the crests of one wave arrive at the same time as the troughs of the other wave, and so they add to produce zero amplitude (Fig. $24-8b$). This is **destructive interference**, and the screen is dark, Fig. 24–7c. Thus, there will be a series of bright and dark lines (or fringes) on the viewing screen.

FIGURE 24-7 How the wave theory explains the pattern of lines seen in the double-slit experiment. (a) At the center of the screen the waves from each slit travel the same distance and are in phase. (b) At this angle θ , the lower wave travels an extra distance of one whole wavelength, and the waves are in phase; note from the shaded triangle that the path difference equals $d \sin \theta$. (c) For this angle θ , the lower wave travels an extra distance equal to one-half wavelength, so the two waves arrive at the screen fully out of phase. (d) A more detailed diagram showing the geometry for parts (b) and (c) .

To determine exactly where the bright lines fall, first note that Fig. 24–7 is somewhat exaggerated; in real situations, the distance d between the slits is very small compared to the distance L to the screen. The rays from each slit for each case will therefore be essentially parallel, and θ is the angle they make with the horizontal as shown in Fig. 24-7d. From the shaded right triangles shown in Figs. 24–7b and c, we can see that the extra distance traveled by the lower ray is $d \sin \theta$ (seen more clearly in Fig. 24-7d). Constructive interference will occur, and a bright fringe will appear on the screen, when the path difference, $d \sin \theta$, equals a whole number of wavelengths:

> constructive $d \sin \theta = m\lambda$, $m = 0, 1, 2, \cdots$ interference $(24-2a)$ (bright)

The value of m is called the **order** of the interference fringe. The first order $(m = 1)$, for example, is the first fringe on each side of the central fringe (which is at $\theta = 0$, $m = 0$). Destructive interference occurs when the path difference d sin θ is $\frac{1}{2}\lambda$, $\frac{3}{2}\lambda$, and so on:

$$
d \sin \theta = (m + \frac{1}{2})\lambda, \qquad m = 0, 1, 2, \cdots
$$
\n
$$
\begin{array}{c}\n\text{destructive}\n\text{interference}\n\end{array}\n\quad (24-2b)
$$

The bright fringes are peaks or maxima of light intensity, the dark fringes are minima. The intensity of the bright fringes is greatest for the central fringe $(m = 0)$ and decreases for higher orders, as shown in Fig. 24–9. How much the intensity decreases with increasing order depends on the width of the two slits.

FIGURE 24-8 Two traveling waves are waves shown undergoing (a) constructive interference, (b) destructive interference. (See also Section 11-12.)

 (b)

FIGURE 24-9 (a) Interference fringes produced by a double-slit experiment and detected by photographic film placed on the viewing screen. The arrow marks the central fringe. (b) Graph of the intensity of light in the interference pattern. Also shown are values of m for Eq. 24-2a (constructive interference) and Eq. 24-2b (destructive interference).

SECTION 24-3 Interference-Young's Double-Slit Experiment 669

EXAMPLE 24-1 Line spacing for double-slit interference. A screen containing two slits 0.100 mm apart is 1.20 m from the viewing screen. Light of wavelength $\lambda = 500$ nm falls on the slits from a distant source. Approximately how far apart will adjacent bright interference fringes be on the screen?

APPROACH The angular position of bright (constructive interference) fringes is found using Eq. 24–2a. The distance between the first two fringes (say) can be found using right triangles as shown in Fig. 24-10.

SOLUTION Given $d = 0.100$ mm = 1.00×10^{-4} m, $\lambda = 500 \times 10^{-9}$ m, and $L = 1.20$ m, the first-order fringe ($m = 1$) occurs at an angle θ given by

$$
\sin \theta_1 = \frac{m\lambda}{d} = \frac{(1)(500 \times 10^{-9} \,\mathrm{m})}{1.00 \times 10^{-4} \,\mathrm{m}} = 5.00 \times 10^{-3}.
$$

This is a very small angle, so we can take $\sin \theta \approx \theta$, with θ in radians. The firstorder fringe will occur a distance x_1 above the center of the screen (see Fig. 24–10), given by $x_1/L = \tan \theta_1 \approx \theta_1$, so

 $x_1 \approx L\theta_1 = (1.20 \,\mathrm{m})(5.00 \times 10^{-3}) = 6.00 \,\mathrm{mm}.$

The second-order fringe $(m = 2)$ will occur at

$$
x_2 \approx L\theta_2 = L\frac{2\lambda}{d} = 12.0 \text{ mm}
$$

above the center, and so on. Thus the lower order fringes are 6.00 mm apart.

FIGURE 24-10 Examples 24-1 and 24-2. For small angles, the interference fringes occur at distance $x = \theta L$ above the center fringe ($m = 0$); θ_1 and x_1 are for the first-order fringe $(m = 1)$, θ_2 and x_2 are for $m = 2$.

CONCEPTUAL EXAMPLE 24-2 Changing the wavelength. (a) What happens to the interference pattern shown in Fig. 24–10, Example 24–1, if the incident light (500 nm) is replaced by light of wavelength 700 nm? (b) What happens instead if the wavelength stays at 500 nm but the slits are moved farther apart?

RESPONSE (a) When λ increases in Eq. 24–2a but d stays the same, then the angle θ for bright fringes increases and the interference pattern spreads out. (b) Increasing the slit spacing d reduces θ for each order, so the lines are closer together.

From Eqs. 24–2 we can see that, except for the zeroth-order fringe at the center, the position of the fringes depends on wavelength. Consequently, when white light falls on the two slits, as Young found in his experiments, the central fringe is white, but the first- (and higher-) order fringes contain a spectrum of colors like a rainbow; θ was found to be smallest for violet light and largest for red (Fig. 24–11). By measuring the position of these fringes, Young was the first to determine the wavelengths of visible light (using Eqs. 24–2). In doing so, he showed that what distinguishes different colors physically is their wavelength (or frequency), an idea put forward earlier by Grimaldi in 1665.

EXAMPLE 24-3 Wavelengths from double-slit interference. White light passes through two slits 0.50 mm apart, and an interference pattern is observed on a screen 2.5 m away. The first-order fringe resembles a rainbow with violet and red light at opposite ends. The violet light falls about 2.0 mm and the red 3.5 mm from the center of the central white fringe (Fig. 24–11). Estimate the wavelengths for the violet and red light.

Wavelength (or *frequency*) determines color

FIGURE 24-11 First-order fringes are a full spectrum, like a rainbow. Also Example 24-3.

670 CHAPTER 24 The Wave Nature of Light

 \bigcirc CAUTION Use the approximation $\theta \approx \tan \theta$ or $\theta \approx \sin \theta$ only if θ is small and in radians

APPROACH We find the angles for violet and red light from the distances given and the diagram of Fig. 24-10. Then we use Eq. 24-2a to obtain the wavelengths. Because 3.5 mm is much less than 2.5 m, we can use the smallangle approximation.

SOLUTION We use Eq. 24–2a with $m = 1$ and $\sin \theta \approx \tan \theta \approx \theta$. Then for violet light, $x = 2.0$ mm, so (see also Fig. 24–10)

$$
\lambda = \frac{d \sin \theta}{m} \approx \frac{d\theta}{m} \approx \frac{d}{m} \frac{x}{L} = \left(\frac{5.0 \times 10^{-4} \,\mathrm{m}}{1}\right) \left(\frac{2.0 \times 10^{-3} \,\mathrm{m}}{2.5 \,\mathrm{m}}\right) = 4.0 \times 10^{-7} \,\mathrm{m},
$$

or 400 nm. For red light, $x = 3.5$ mm, so

$$
\lambda = \frac{d}{m} \frac{x}{L} = \left(\frac{5.0 \times 10^{-4} \text{ m}}{1}\right) \left(\frac{3.5 \times 10^{-3} \text{ m}}{2.5 \text{ m}}\right) = 7.0 \times 10^{-7} \text{ m} = 700 \text{ nm}.
$$

EXERCISE A For the setup in Example 24–3, how far from the central white fringe is the first-order fringe for green light $\lambda = 500$ nm?

Coherent Light

The two slits in Fig. 24–7 act as if they were two sources of radiation. They are called coherent sources because the waves leaving them have the same wavelength and frequency, and bear the same phase relationship to each other at all times. This happens because the waves come from a single source to the left of the two slits in Fig. 24–7. An interference pattern is observed only when the sources are coherent. If two tiny lightbulbs replaced the two slits, an interference pattern would not be seen. The light emitted by one lightbulb would have a random phase with respect to the second bulb, and the screen would be more or less uniformly illuminated. Two such sources, whose output waves bear no fixed phase relationship to each other, are called incoherent sources.

Coherent and incoherent sources

Interference patterns occur only if sources are coherent

The Visible Spectrum and Dispersion

The two most obvious properties of light are readily describable in terms of the wave theory of light: intensity (or brightness) and color. The **intensity** of light is the energy it carries per unit area per unit time, and is related to the square of the amplitude of the wave, just as for any wave (see Section $11-10$, or Eqs. 22-7 and 22–8). The **color** of the light is related to the frequency f or wavelength λ of the light. (Recall $\lambda f = c = 3.0 \times 10^8 \text{ m/s}$, Eq. 22–4.) Visible light—that to which our eyes are sensitive—consists of frequencies from 4×10^{14} Hz to 7.5×10^{14} Hz, corresponding to wavelengths in air of about 400 nm to 750 nm.[†] This is known as the visible spectrum, and within it lie the different colors from violet to red, as shown in Fig. 24–12. Light with wavelength shorter than 400 nm is called **ultraviolet** (UV), and light with wavelength longer than 750 nm is called **infrared** (IR) .^{\ddagger} Although human eves are not sensitive to UV or IR, some types of photographic film and other detectors do respond to them.

[†]Sometimes the angstrom (Å) unit is used when referring to light: $1 \text{ Å} = 1 \times 10^{-10} \text{m}$. Visible light has wavelengths in air of 4000 Å to 7500 Å.

[‡]The complete electromagnetic spectrum is illustrated in Fig. 22-8.

SECTION 24-4 The Visible Spectrum and Dispersion 671

FIGURE 24-13 White light passing through a prism is broken down into its constituent colors.

[The wavelengths of visible light are measured in air to be 400 nm to 750 nm, and this range is what we usually quote. But, as we shall see in Chapter 25, the interior of the eye is filled with a fluid with index of refraction $n \approx 1.4$, so the wavelengths where they actually reach our retinas are smaller by this factor, Eq. 24–1.]

A prism separates white light into a rainbow of colors, as shown in Fig. 24–13. This happens because the index of refraction of a material depends on the wavelength, as shown for several materials in Fig. $24-14$. White light is a mixture of all visible wavelengths, and when incident on a prism, as in Fig. 24–15, the different wavelengths are bent to varying degrees. Because the index of refraction is greater for the shorter wavelengths, violet light is bent the most and red the least. This spreading of white light into the full spectrum is called dispersion.

FIGURE 24-16 (a) Ray diagram

Rainbows are a spectacular example of dispersion-by drops of water. You can see rainbows when you look at falling water droplets with the Sun behind you. Figure 24-16 shows how red and violet rays are bent by spherical water droplets and are reflected off the back surface. Red is bent the least and so reaches the observer's eyes from droplets higher in the sky, as shown in the diagram. Thus the top of the rainbow is red.

Diamonds achieve their brilliance (Fig. $24-17$) from a combination of dispersion and total internal reflection. Because diamonds have a very high index of refraction of about 2.4, the critical angle for total internal reflection is only 25° . The light dispersed into a spectrum inside the diamond therefore strikes many of the internal surfaces before it strikes one at less than 25° and emerges. After many such reflections, the light has traveled far enough that the colors have become sufficiently separated to be seen individually and brilliantly by the eye after leaving the crystal.

The visible spectrum, Fig. 24-12, does not show all the colors seen in nature. For example, there is no brown in Fig. 24–12. Many of the colors we see are a mixture of wavelengths. For practical purposes, most natural colors can be reproduced using three primary colors. They are red, green, and blue for direct source viewing such as TV and computer monitors. For inks used in printing, the primary colors are cyan (the color of the margin notes in this book), yellow, and magenta (the color we use for light rays in diagrams).

24–5 Diffraction by a Single Slit or Disk

Young's double-slit experiment put the wave theory of light on a firm footing. But full acceptance came only with studies on diffraction (Section 24–1) more than a decade later, in the 1810s and 1820s.

We have already discussed diffraction briefly with regard to water waves (Section $11-15$) as well as for light (Section $24-1$), and we have seen that it refers to the spreading or bending of waves around edges. Let's look in more detail.

In 1819 Augustin Fresnel (1788–1827) presented to the French Academy a wave theory of light that predicted and explained interference and diffraction effects. Almost immediately Siméon Poisson (1781-1840) pointed out a counterintuitive inference: according to Fresnel's wave theory, if light from a point source were to fall on a solid disk, part of the incident light would be diffracted around the edges and would constructively interfere at the center of the shadow (Fig. 24–18). That prediction seemed very unlikely. But when the experiment was actually carried out by Francois Arago, the bright spot was seen at the very center of the shadow (Fig. 24–19a). This was strong evidence for the wave theory.

Figure 24–19a is a photograph of the shadow cast by a coin using a (nearly) point source of light, a laser in this case. The bright spot is clearly present at the center. Notice also the bright and dark fringes beyond the shadow. These resemble the interference fringes of a double slit. Indeed, they are due to interference of waves diffracted around the disk, and the whole is referred to as a diffraction pattern. A diffraction pattern exists around any sharp object illuminated by a point source, as shown in Figs. 24–19b and c. We are not always aware of them because most sources of light in everyday life are not points, so light from different parts of the source washes out the pattern.

FIGURE 24-18 If light is a wave, a bright spot will appear at the center of the shadow of a solid disk illuminated by a point source of monochromatic light.

The (un)expected diffraction spot

FIGURE 24-19 Diffraction pattern of (a) a circular disk (a coin), (b) scissors, (c) a single slit, each illuminated by a (nearly) point source of monochromatic light.

 (a)

To see how a diffraction pattern arises, we will analyze the important case of monochromatic light passing through a narrow slit. We will assume that parallel rays (plane waves) of light fall on the slit of width D , and pass through to a viewing screen very far away.[†] As we know from studying water waves and from Huygens' principle, the waves passing through the slit spread out in all directions. We will now examine how the waves passing through different parts of the slit interfere with each other.

Parallel rays of monochromatic light pass through the narrow slit as shown in Fig. 24–20a. The light falls on a screen which is assumed to be very far away, so the rays heading for any point are very nearly parallel before they meet at the screen. First we consider rays that pass straight through as in Fig. 24–20a. They are all in phase, so there will be a central bright spot on the screen. In Fig. 24–20b, we consider rays moving at an angle θ such that the ray from the top of the slit travels exactly one wavelength farther than the ray from the bottom edge to reach the screen. The ray passing through the very center of the slit will travel one-half wavelength farther than the ray at the bottom of the slit. These two rays will be exactly out of phase with one another and so will destructively interfere when they overlap at the screen. Similarly, a ray slightly above the bottom one will cancel a ray that is the same distance above the central one. Indeed, each ray passing through the lower half of the

FIGURE 24-20 Analysis of diffraction pattern formed by light passing through a narrow slit.

slit will cancel with a corresponding ray passing through the upper half. Thus, all the rays destructively interfere in pairs, and so the light intensity will be zero on the viewing screen at this angle. The angle θ at which this takes place can be seen from Fig. 24–20b to occur when $\lambda = D \sin \theta$, so

 $\sin \theta = \frac{\lambda}{D}$. [first minimum] $(24-3a)$

The light intensity is a maximum at $\theta = 0^{\circ}$ and decreases to a minimum (intensity = zero) at the angle θ given by Eq. 24–3a.

Now consider a larger angle θ such that the top ray travels $\frac{3}{2}\lambda$ farther than the bottom ray, as in Fig. 24-20c. In this case, the rays from the bottom third of the slit will cancel in pairs with those in the middle third because they will be $\lambda/2$ out of phase. However, light from the top third of the slit will still reach the screen, so there will be a bright spot centered near $\sin \theta \approx 3\lambda/2D$, but it will not be nearly as bright as the central spot at $\theta = 0^{\circ}$. For an even larger angle θ such that the top ray travels 2λ farther than the bottom ray, Fig. 24–20d, rays from the bottom quarter of the slit will cancel with those in the quarter just above it because the path lengths differ by $\lambda/2$. And the rays through the quarter of the slit just above center will cancel with those through the top quarter. At this angle there will again be a minimum of zero intensity in the diffraction

[†]If the viewing screen is not far away, lenses can be used to make the rays parallel.

Diffraction equation (angular half width of central spot)

FIGURE 24-21 Intensity in the diffraction pattern of a single slit as a function of $\sin \theta$. Note that the central maximum is not only much higher than the maxima to each side, but it is also twice as wide $(2\lambda/D)$ wide) as any of the others (only λ/D wide each).

pattern. A plot of the intensity as a function of angle is shown in Fig. 24–21. This corresponds well with the photo of Fig. 24–19c. Notice that minima (zero intensity) occur at

$$
D\sin\theta = m\lambda, \qquad m = 1, 2, 3, \cdots, \qquad \qquad \text{[minimal]} \text{ (24-3b)}
$$

but *not* at $m = 0$ where there is the strongest maximum. Between the minima, smaller intensity maxima occur at approximately (not exactly) $m \approx \frac{3}{2}, \frac{5}{2}, \cdots$

Note that the *minima* for a diffraction pattern, Eq. 24–3b, satisfy a criterion that looks very similar to that for the *maxima* (bright spots) for double-slit interference, Eq. 24–2a. Also note that D is a single slit width, whereas d in Eq. $24-2$ is the distance between two slits.

EXAMPLE 24-4 Single-slit diffraction maximum. Light of wavelength 750 nm passes through a slit 1.0×10^{-3} mm wide. How wide is the central maximum (a) in degrees, and (b) in centimeters, on a screen 20 cm away?

APPROACH The width of the central maximum goes from the first minimum on one side to the first minimum on the other side. We use Eq. 24–3a to find the angular position of the first single-slit diffraction minimum.

SOLUTION (*a*) The first minimum occurs at

$$
\sin \theta = \frac{\lambda}{D} = \frac{7.5 \times 10^{-7} \,\mathrm{m}}{1 \times 10^{-6} \,\mathrm{m}} = 0.75.
$$

So $\theta = 49^{\circ}$. This is the angle between the center and the first minimum, Fig. 24–22. The angle subtended by the whole central maximum, between the minima above and below the center, is twice this, or 98°.

(b) The width of the central maximum is 2x, where $\tan \theta = x/20$ cm. So $2x = 2(20 \text{ cm})(\tan 49^\circ) = 46 \text{ cm}.$

NOTE A large width of the screen will be illuminated, but it will not normally be very bright since the amount of light that passes through such a small slit will be small and it is spread over a large area. Note also that we *cannot* use the small-angle approximation here $(\theta \approx \sin \theta \approx \tan \theta)$ because θ is large.

EXERCISE B In Example 24-4, red light ($\lambda = 750$ nm) was used. If instead yellow light ($\lambda = 550$ nm) had been used, would the central maximum be wider or narrower?

CONCEPTUAL EXAMPLE 24-5 Diffraction spreads. Light shines through a rectangular hole that is narrower in the vertical direction than the horizontal, Fig. 24–23. (a) Would you expect the diffraction pattern to be more spread out in the vertical direction or in the horizontal direction? (b) Should a rectangular loudspeaker horn at a stadium be high and narrow, or wide and flat?

RESPONSE (a) From Eq. 24–3a we can see that if we make the slit (width D) narrower, the pattern spreads out more. This is consistent with our study of waves in Chapter 11. The diffraction through the rectangular hole will be wider vertically, since the opening is smaller in that direction.

 (b) For a loudspeaker, the sound pattern desired is one spread out horizontally, so the horn should be tall and narrow (rotate Fig. $24-23$ by 90°).

Single-slit diffraction minima

CAUTION

Don't confuse Eqs. 24-2 for interference with Eqs. 24-3 for diffraction; note the differences

FIGURE $24-22$ Example $24-4$.

FIGURE 24-24 Diffraction grating.

Diffraction grating $maxima (m = order)$

CAUTION Diffraction grating is analyzed using interference formulas, not diffraction formulas

Why more slits yield sharper peaks

FIGURE 24-25 Intensity as a function of viewing angle θ (or position on the screen) for (a) two slits, (b) six slits. For a diffraction grating, the number of slits is very large ($\approx 10^4$) and the peaks are narrower still.

A large number of equally spaced parallel slits is called a diffraction grating, although the term "interference grating" might be as appropriate. Gratings can be made by precision machining of very fine parallel lines on a glass plate. The untouched spaces between the lines serve as the slits. Photographic transparencies of an original grating serve as inexpensive gratings. Gratings containing 10,000 lines per centimeter are common, and are very useful for precise measurements of wavelengths. A diffraction grating containing slits is called a transmission grating. Another type of diffraction grating is the reflection grating, made by ruling fine lines on a metallic or glass surface from which light is reflected and analyzed. The analysis is basically the same as for a transmission grating, which we now discuss.

The analysis of a diffraction grating is much like that of Young's double-slit experiment. We assume parallel rays of light are incident on the grating as shown in Fig. 24-24. We also assume that the slits are narrow enough so that diffraction by each of them spreads light over a very wide angle on a distant screen beyond the grating, and interference can occur with light from all the other slits. Light rays that pass through each slit without deviation ($\theta = 0^{\circ}$) interfere constructively to produce a bright line at the center of the screen. Constructive interference also occurs at an angle θ such that rays from adjacent slits travel an extra distance of $\Delta l = m\lambda$, where m is an integer. If d is the distance between slits, then we see from Fig. 24–24 that $\Delta l = d \sin \theta$, and

$$
\sin \theta = \frac{m\lambda}{d}, \qquad m = 0, 1, 2, \cdots \qquad \qquad \text{[principal maximal]} \text{ (24-4)}
$$

is the criterion to have a brightness maximum. This is the same equation as for the double-slit situation, and again m is called the order of the pattern.

There is an important difference between a double-slit and a multipleslit pattern. The bright maxima are much *sharper* and *narrower* for a grating. Why? Suppose that the angle θ is increased just slightly beyond that required for a maximum. In the case of only two slits, the two waves will be only slightly out of phase, so nearly full constructive interference occurs. This means the maxima are wide (see Fig. $24-10$). For a grating, the waves from two adjacent slits will also not be significantly out of phase. But waves from one slit and those from a second one a few hundred slits away may be exactly out of phase; all or nearly all the light can cancel in pairs in this way. For example, suppose the angle θ is very slightly different from its first-order maximum, so that the extra path length for a pair of adjacent slits is not exactly λ but rather 1.0010 λ . The wave through one slit and another one 500 slits below will have a path difference of $1\lambda + (500)(0.001\lambda) = 1.5000\lambda$, or $1\frac{1}{2}$ wavelengths, so the two will cancel. A pair of slits, one below each of these, will also cancel. That is, the light from slit 1 cancels with that from slit 501; light from slit 2 cancels with that from slit 502, and so on. Thus even for a tiny angle[†] corresponding to an extra path length of $\frac{1}{1000} \lambda$, there is much destructive interference, and so the maxima are very narrow. The more lines there are in a grating, the sharper will be the peaks (see Fig. 24-25). Because a grating produces much sharper (and brighter) lines than two slits alone can, it is a far more precise device for measuring wavelengths.

Suppose the light striking a diffraction grating is not monochromatic, but consists of two or more distinct wavelengths. Then for all orders other than $m = 0$, each wavelength will produce a maximum at a different angle (Fig. 24–26a), just as for a double slit. If white light strikes a grating, the central $(m = 0)$ maximum will be a sharp white peak. But for all other orders, there

676 CHAPTER 24 The Wave Nature of Light

FIGURE 24-26 Spectra produced by a grating: (a) two wavelengths, 400 nm and 700 nm; (b) white light. The second order will normally be dimmer than the first order. (Higher orders are not shown.) If grating spacing is small enough, the second and higher orders will be missing.

will be a distinct spectrum of colors spread out over a certain angular width, Fig. 24–26b. Because a diffraction grating spreads out light into its component wavelengths, the resulting pattern is called a spectrum.

EXAMPLE 24-6 Diffraction grating: lines. Determine the angular positions of the first- and second-order maxima for light of wavelength 400 nm and 700 nm incident on a grating containing 10,000 lines/cm.

APPROACH First we find the distance d between grating lines: if the grating has N lines in 1 m, then the distance between lines must be $d = 1/N$ meters. Then we use Eq. 24–4 to find the angles for the two wavelengths for $m = 1$ and 2. **SOLUTION** The grating contains 1.00×10^4 lines/cm = 1.00×10^6 lines/m, which means the distance between lines is $d = (1/1.00 \times 10^6)$ m = 1.00×10^{-6} m = 1.00 μ m. In first order (m = 1), the angles are

$$
\sin \theta_{400} = \frac{m\lambda}{d} = \frac{(1)(4.00 \times 10^{-7} \text{ m})}{1.00 \times 10^{-6} \text{ m}} = 0.400
$$

$$
\sin \theta_{700} = \frac{(1)(7.00 \times 10^{-7} \text{ m})}{1.00 \times 10^{-6} \text{ m}} = 0.700
$$

so $\theta_{400} = 23.6^{\circ}$ and $\theta_{700} = 44.4^{\circ}$. In second order,

$$
\sin \theta_{400} = \frac{2\lambda}{d} = \frac{(2)(4.00 \times 10^{-7} \text{ m})}{1.00 \times 10^{-6} \text{ m}} = 0.800
$$

$$
\sin \theta_{700} = \frac{(2)(7.00 \times 10^{-7} \text{ m})}{1.00 \times 10^{-6} \text{ m}} = 1.40
$$

so $\theta_{400} = 53.1^{\circ}$. But the second order does not exist for $\lambda = 700$ nm because $\sin \theta$ cannot exceed 1. No higher orders will appear.

EXAMPLE 24-7 Spectra overlap. White light containing wavelengths from 400 nm to 750 nm strikes a grating containing 4000 lines/cm. Show that the blue at $\lambda = 450 \text{ nm}$ of the third-order spectrum overlaps the red at 700 nm of the second order.

APPROACH We use Eq. 24–4 to calculate the angular positions of the $m = 3$ blue maximum and the $m = 2$ red one.

SOLUTION The grating spacing is $d = (1/4000)$ cm = 2.50 \times 10⁻⁶ m. The blue of the third order occurs at an angle θ given by

$$
\sin \theta = \frac{m\lambda}{d} = \frac{(3)(4.50 \times 10^{-7} \,\mathrm{m})}{(2.50 \times 10^{-6} \,\mathrm{m})} = 0.540.
$$

Red in second order occurs at

$$
\sin \theta = \frac{(2)(7.00 \times 10^{-7} \,\mathrm{m})}{(2.50 \times 10^{-6} \,\mathrm{m})} = 0.560
$$

which is a greater angle; so the second order overlaps into the beginning of the third-order spectrum.

EXERCISE C How many lines per cm are in a grating that produces the first-order maximum of 633-nm light at 18°?

EXERCISE D You are shown the spectra produced by red light shining through two different gratings. The lines in spectrum A are farther apart than those in spectrum B. Which grating has more lines/cm?

24–7 The Spectrometer and Spectroscopy

A spectrometer or spectroscope, Fig. $24-27$, is a device to measure wavelengths accurately using a diffraction grating (or a prism) to separate different wavelengths of light. Light from a source passes through a narrow slit S in the "collimator." The slit is at the focal point of the lens L, so parallel light falls on the grating. The movable telescope can bring the rays to a focus.

FIGURE 24-27 Spectrometer or spectroscope.

> Nothing will be seen in the viewing telescope unless it is positioned at an angle θ that corresponds to a diffraction peak (first order is usually used) of a wavelength emitted by the source. The angle θ can be measured to very high accuracy, so the wavelength of a line can be determined to high accuracy using Eq. 24–4:

$$
\lambda = \frac{d}{m} \sin \theta,
$$

where m is an integer representing the order, and d is the distance between grating lines. The line you see in a spectrometer corresponding to each wavelength is actually an image of the slit S. The narrower the slit, the narrower—but dimmer-the line is, and the more precisely we can measure its angular position. If the light contains a continuous range of wavelengths, then a continuous spectrum is seen in the spectroscope.

In many spectrometers, a reflection grating is used, and sometimes a prism. A prism works because of dispersion (Section 24–4), bending light of different wavelengths into different angles. (A prism is not a linear device and must be calibrated.)

Line spectra

An important use of a spectrometer is for the identification of atoms or molecules. When a gas is heated or an electric current is passed through it, the gas emits a characteristic line spectrum. That is, only certain discrete wavelengths of light are emitted, and these are different for different elements and compounds.[†] Figure 24–28 shows the line spectra for a number of elements in the gas state. Line spectra occur only for gases at high temperatures and low pressure and density. The light from heated solids, such as a lightbulb filament, and even from a dense gaseous object such as the Sun, produces a continuous spectrum including a wide range of wavelengths.

Figure 24-28 also shows the Sun's "continuous spectrum," which contains a number of *dark* lines (only the most prominent are shown), called absorption lines. Atoms and molecules can absorb light at the same wavelengths at which they emit light. The Sun's absorption lines are due to absorption by atoms and molecules in the cooler outer atmosphere of the Sun, as well as by atoms and molecules in the Earth's atmosphere. A careful analysis of all these thousands of

Why atoms and molecules emit line spectra was a great mystery for many years and played a central role in the development of modern quantum theory, as we shall see in Chapter 27.

Solar absorption spectrum

lines reveals that at least two-thirds of all elements are present in the Sun's atmosphere. The presence of elements in the atmosphere of other planets, in interstellar space, and in stars is also determined by spectroscopy.

Spectroscopy is useful for determining the presence of certain types of molecules in laboratory specimens where chemical analysis would be difficult. For example, biological DNA and different types of protein absorb light in particular regions of the spectrum (such as in the UV). The material to be examined, which is often in solution, is placed in a monochromatic light beam whose wavelength is selected by placement angle of a diffraction grating or prism. The amount of absorption, as compared to a standard solution without the specimen, can reveal not only the presence of a particular type of molecule, but also its concentration.

Light emission and absorption also occur outside the visible part of the spectrum, such as in the UV and IR regions. Glass absorbs light in these regions, so reflection gratings and mirrors (in place of lenses) are used. Special types of film or detectors are used for detection.

24-8 Interference by Thin Films

Interference of light gives rise to many everyday phenomena such as the bright colors reflected from soap bubbles and from thin oil films on water, Fig. 24-29. In these and other cases, the colors are a result of constructive interference between light reflected from the two surfaces of the thin film. The effect is present only if the thickness of the film is on the order of the wavelength of the light. If the film thickness is greater than a few wavelengths, the effect gets washed out.

 (c)

by spectroscopy

FIGURE 24-29 Thin-film interference patterns seen in (a) soap bubbles, (b) a thin film of soapy water, and (c) a thin layer of oil on the water of a street puddle.

FIGURE 24-30 Light reflected from the upper and lower surfaces of a thin film of oil lying on water. This analysis assumes the light strikes the surface nearly perpendicularly, but is shown here at an angle so we can display each ray.

To see how this **thin-film interference** happens, consider a smooth surface of water on top of which is a thin uniform layer of another substance, say an oil whose index of refraction is less than that of water (we'll see why we assume this in a moment); see Fig. 24–30. Assume for the moment that the incident light is of a single wavelength. Part of the incident light is reflected at A on the top surface, and part of the light transmitted is reflected at B on the lower surface. The part reflected at the lower surface must travel the extra distance ABC. If this *path difference* ABC equals one or a whole number of wavelengths in the film (λ_n) , the two waves will reach the eye in phase and interfere constructively. Hence the region AC on the surface film will appear bright. But if ABC equals $\frac{1}{2}\lambda_n$, $\frac{3}{2}\lambda_n$, and so on, the two waves will be exactly out of phase and destructive interference occurs: the area AC on the film will be dark. The wavelength λ_n is the wavelength in the film: $\lambda_n = \lambda/n$, where *n* is the index of refraction in the film and λ is the wavelength in vacuum. See Eq. 24-1.

When white light falls on such a film, the path difference ABC will equal λ_n (or $m\lambda_n$, with $m =$ an integer) for only one wavelength at a given viewing angle. The color corresponding to λ (λ in air) will be seen as very bright. For light viewed at a slightly different angle, the path difference ABC will be longer or shorter and a different color will undergo constructive interference. Thus, for an extended (nonpoint) source emitting white light, a series of bright colors will be seen next to one another. Variations in thickness of the film will also alter the path difference ABC and therefore affect the color of light that is most strongly reflected.

When a curved glass surface is placed in contact with a flat glass surface, Fig. 24-31, a series of concentric rings is seen when illuminated from above by

Newton's rings

FIGURE 24-32 (a) Reflected ray changes phase by 180 $^{\circ}$ or $\frac{1}{2}$ cycle if $n_2 > n_1$, but (b) does not if $n_2 < n_1$.

monochromatic light. These are called Newton's rings¹ and they are due to interference between rays reflected by the top and bottom surfaces of the very thin *air* gap between the two pieces of glass. Because this gap (which is equivalent to a thin film) increases in width from the central contact point out to the edges, the extra path length for the lower ray (equal to BCD) varies; where it equals $0, \frac{1}{2}\lambda$, λ , $\frac{3}{2}\lambda$, 2λ , and so on, it corresponds to constructive and destructive interference; and this gives rise to the series of bright and dark lines seen in Fig. 24-31b.

The point of contact of the two glass surfaces $(A \text{ in Fig. 24-31a})$ is dark in Fig. 24–31b. Since the path difference is zero here, our previous analysis would suggest that the rays reflected from each surface are in phase and so this central point ought to be bright. But it is dark, which tells us something else is happening here: the two rays must be completely out of phase. This can happen only because one of the waves, upon reflection, flips over—a crest becomes a trough—see Fig. 24–32. We say the wave has undergone a phase change of 180° , or of half a wave cycle. Indeed, this and other experiments reveal that, at normal incidence, a beam of light reflected by a material with index of refraction greater than that of the material in which it is traveling, changes phase by 180° or $\frac{1}{2}$ cycle; see Fig. 24–32. This phase change acts just like a path difference of $\frac{1}{2}\lambda$. If the index of refraction is less than that of the material in which the light is traveling, no phase change occurs. [†]Although Newton gave an elaborate description of them, they had been first observed and described by his contemporary, Robert Hooke.

Thus the ray reflected by the curved surface above the air gap in Fig. 24-31a undergoes no change in phase. The ray reflected at the lower surface, where the beam in air strikes the glass, undergoes a $\frac{1}{2}$ -cycle phase change, equivalent to a $\frac{1}{2}\lambda$ path difference. Thus the two rays reflected at the point of contact A of the two glass surfaces (where the air gap approaches zero thickness) will be a half cycle (or 180°) out of phase, and a dark spot occurs. Other dark bands will occur when the path difference BCD in Fig. 24–31a is equal to an integral number of wavelengths. Bright bands will occur when the path difference is $\frac{1}{2}\lambda$, $\frac{3}{2}\lambda$, and so on, because the phase change at one surface effectively adds a path difference of $\frac{1}{2}\lambda (= \frac{1}{2}$ cycle).

Returning for a moment to Fig. 24-30, the light reflecting at both interfaces, air-oil and oil-water, underwent a phase change of 180° equivalent to a path difference of $\frac{1}{2}\lambda$, since we assumed $n_{\text{water}} > n_{\text{oil}} > n_{\text{air}}$; since the phase changes were equal, they didn't affect our analysis.

EXAMPLE 24-8 Thin film of air, wedge-shaped. A very fine wire 7.35×10^{-3} mm in diameter is placed between two flat glass plates as in Fig. 24–33a. Light whose wavelength in air is 600 nm falls (and is viewed) perpendicular to the plates, and a series of bright and dark bands is seen, Fig. 24-33b. How many light and dark bands will there be in this case? Will the area next to the wire be bright or dark?

APPROACH We need to consider two effects: (1) path differences for rays reflecting from the two close surfaces (thin wedge of air between the two glass plates), and (2) the $\frac{1}{2}$ -cycle phase change at the lower surface (point E in Fig. 24–33a), where rays in air can enter glass. Because of the phase change at the lower surface, there will be a dark band when the path difference is $0, \lambda$, 2λ , 3λ , and so on. Since the light rays are perpendicular to the plates, the extra path length equals 2t, where t is the thickness of the air gap at any point.

SOLUTION Dark bands will occur where

$$
2t = m\lambda, \qquad m = 0, 1, 2, \cdots
$$

Bright bands occur when $2t = (m + \frac{1}{2})\lambda$, where *m* is an integer. At the position of the wire, $t = 7.35 \times 10^{-6}$ m. At this point there will be $2t/\lambda = (2)(7.35 \times 10^{-6} \text{ m})/(6.00 \times 10^{-7} \text{ m}) = 24.5$ wavelengths. This is a "half integer," so the area next to the wire will be bright. There will be a total of 25 dark lines along the plates, corresponding to path lengths of 0 λ , 1 λ , 2 λ , 3 λ , ..., 24 λ , including the one at the point of contact A (m = 0). Between them, there will be 24 bright lines plus the one at the end, or 25.

NOTE The bright and dark bands will be straight only if the glass plates are extremely flat. If they are not, the pattern is uneven, as in Fig. 24-33c. Thus we see a very precise way of testing a glass surface for flatness. Spherical lens surfaces can be tested for precision by placing the lens on a flat glass surface and observing Newton's rings (Fig. 24–31b) for perfect circularity.

If the wedge between the two glass plates of Example 24–8 is filled with some transparent substance other than air—say, water—the pattern shifts because the wavelength of the light changes. In a material where the index of refraction is n , the wavelength is $\lambda_n = \lambda/n$, where λ is the wavelength in vacuum (see Eq. 24–1). For instance, if the thin wedge of Example 24–8 were filled with water, then $\lambda_n = 600 \text{ nm}/1.33 = 450 \text{ nm}$; instead of 25 dark lines, there would be 33.

When white light (rather than monochromatic light) is incident on the thin wedge of air in Figs. 24–31a or 24–33a, a colorful series of fringes is seen. This is because constructive interference occurs for different wavelengths in the reflected light at different thicknesses along the wedge.

FIGURE 24-33 (a) Light rays reflected from the upper and lower surfaces of a thin wedge of air interfere to produce bright and dark bands. (b) Pattern observed when glass plates are optically flat; (c) pattern when plates are not so flat. See Example 24-8.

FIGURE 24-34 Example 24-9. The incident and reflected rays are assumed to be perpendicular to the bubble's surface. They are shown at a slight angle so we can distinguish them.

CAUTION A formula is not enough: you must also check for phase changes at surfaces

PHYSICS APPLIED Lens coatings

FIGURE 24-35 A coated lens. Note color of light reflected from the front lens surface.

A soap bubble is a thin spherical shell (or film) with air inside. The variations in thickness of a soap bubble film gives rise to bright colors reflected from the soap bubble. (There is air on both sides of the bubble film.) Similar variations in film thickness produce the bright colors seen reflecting from a thin layer of oil or gasoline on a puddle or lake (Fig. 24-29). Which wavelengths appear brightest also depends on the viewing angle.

EXAMPLE 24-9 Thickness of soap bubble skin. A soap bubble appears green ($\lambda = 540$ nm) at the point on its front surface nearest the viewer. What is the smallest thickness the soap bubble film could have? Assume $n = 1.35$.

APPROACH Assume the light is reflected perpendicularly from the point on a spherical surface nearest the viewer, Fig. 24–34. The light rays also reflect from the inner surface of the soap bubble film as shown. The path difference of these two reflected rays is 2t, where t is the thickness of the soap film. Light reflected from the first (outer) surface undergoes a 180° phase change (index of refraction of soap is greater than that of air), whereas reflection at the second (inner) surface does not. To determine the thickness t for an interference maximum, we must use the wavelength of light in the soap ($n = 1.35$).

SOLUTION The 180° phase change at only one surface is equivalent to a $\frac{1}{2}\lambda$ path difference. Therefore, green light is bright when the minimum path difference equals $\frac{1}{2}\lambda_n$. Thus, $2t = \lambda/2n$, so

$$
t = \frac{\lambda}{4n} = \frac{(540 \text{ nm})}{(4)(1.35)} = 100 \text{ nm}.
$$

This is the smallest thickness.

NOTE The front surface would also appear green if $2t = 3\lambda/2n$, and, in general, if $2t = (2m + 1)\lambda/2n$, where m is an integer. Note that green is seen in air, so $\lambda = 540$ nm (not λ/n).

An important application of thin-film interference is in the coating of glass to make it "nonreflecting," particularly for lenses. A glass surface reflects about 4% of the light incident upon it. Good-quality cameras, microscopes, and other optical devices may contain six to ten thin lenses. Reflection from all these surfaces can reduce the light level considerably, and multiple reflections produce a background haze that reduces the quality of the image. By reducing reflection, transmission is increased. A very thin coating on the lens surfaces can reduce reflections considerably: the thickness of the film is chosen so that light (at least for one wavelength) reflecting from the front and rear surfaces of the film destructively interferes. The amount of reflection at a boundary depends on the difference in index of refraction between the two materials. Ideally, the coating material should have an index of refraction which is the geometric mean (= $\sqrt{n_1 n_2}$) of those for air and glass, so that the amount of reflection at each surface is about equal. Then destructive interference can occur nearly completely for one particular wavelength depending on the thickness of the coating. Nearby wavelengths will at least partially destructively interfere, but a single coating cannot eliminate reflections for all wavelengths. Nonetheless, a single coating can reduce total reflection from 4% to 1% of the incident light. Often the coating is designed to eliminate the center of the reflected spectrum (around 550 nm). The extremes of the spectrum—red and violet will not be reduced as much. Since a mixture of red and violet produces purple, the light seen reflected from such coated lenses is purple (Fig. 24–35). Lenses containing two or three separate coatings can more effectively reduce a wider range of reflecting wavelengths.

PROBLEM SOLVING Interference

- 1. Interference effects depend on the simultaneous arrival of two or more waves at the same point in space.
- 2. Constructive interference occurs when the waves arrive in phase with each other: a crest of one wave arrives at the same time as a crest of the other wave. The amplitudes of the waves then add to form a larger amplitude. Constructive interference also occurs when the path difference is exactly one full wavelength or any integer multiple of a full wavelength: 1λ , 2λ , 3λ , \cdots .
- 3. Destructive interference occurs when a crest of one wave arrives at the same time as a trough of the

other wave. The amplitudes add, but they are of opposite sign, so the total amplitude is reduced to zero if the two amplitudes are equal. Destructive interference occurs whenever the phase difference is half a wave cycle, or the path difference is a halfintegral number of wavelengths. Thus, the total amplitude will be zero if two identical waves arrive one-half wavelength out of phase, or $(m + \frac{1}{2}) \lambda$ out of phase, where m is an integer.

4. For thin-film interference, an extra half-wavelength phase shift occurs when light reflects from an optically more dense medium (going from a medium of lesser toward greater index of refraction).

EXAMPLE 24-10 Nonreflective coating. What is the thickness of an optical coating of MgF, whose index of refraction is $n = 1.38$ and is designed to eliminate reflected light at wavelengths (in air) around 550 nm when incident normally on glass for which $n = 1.50$?

APPROACH We explicitly follow the procedure outlined in the Problem Solving Box above.

SOLUTION

- (1) Interference effects: Consider two rays reflected from the front and rear surfaces of the coating on the lens as shown in Fig. 24–36. The rays are drawn not quite perpendicular to the lens so we can see each of them. These two reflected rays will interfere with each other.
- (2) Constructive interference: We want to eliminate reflected light, so we do not consider constructive interference.
- (3) Destructive interference: To eliminate reflection, we want reflected rays 1 and 2 to be $\frac{1}{2}$ cycle out of phase with each other so that they destructively interfere. The phase difference is due to the path difference $2t$ traveled by ray 2, as well as any phase change in either ray due to reflection.
- (4) Reflection phase shift: Rays 1 and 2 *both* undergo a change of phase by $\frac{1}{2}$ cycle when they reflect from the coating's front and rear surfaces, respectively (at both surfaces the index of refraction increases). Thus there is no net change in phase due to the reflections. The net phase difference will be due to the extra path 2t taken by ray 2 in the coating, where $n = 1.38$. We want 2t to equal $\frac{1}{2}\lambda_n$ so that destructive interference occurs, where $\lambda_n = \lambda/n$ is the wavelength in the coating. With $2t = \lambda_n/2 = \lambda/2n$, then

$$
t = \frac{\lambda_n}{4} = \frac{\lambda}{4n} = \frac{(550 \text{ nm})}{(4)(1.38)} = 99.6 \text{ nm}.
$$

NOTE We could have set $2t = (m + \frac{1}{2})\lambda_n$, where *m* is an integer. The smallest thickness ($m = 0$) is usually chosen because destructive interference will occur over the widest angle.

NOTE Complete destructive interference occurs only for the given wavelength of visible light. Longer and shorter wavelengths will have only partial cancellation.

FIGURE 24-36 Example 24-10. Incident ray of light is partially reflected at the front surface of a lens coating (ray 1) and again partially reflected at the rear surface of the coating (ray 2), with most of the energy passing as the transmitted ray into the glass.

FIGURE 24-37 Michelson interferometer.

FIGURE 24-38 Transverse waves on a rope polarized (a) in a vertical plane and (b) in a horizontal plane.

24-9 Michelson Interferometer

A useful instrument involving wave interference is the Michelson interferometer (Fig. 24–37),[†] invented by the American Albert A. Michelson (Section 22–4). Monochromatic light from a single point on an extended source is shown striking a half-silvered mirror M_s . This beam splitter mirror M_s has a thin layer of silver that reflects only half the light that hits it, so that half of the beam passes through to a fixed mirror M_2 , where it is reflected back. The other half is reflected by M_s up to a mirror M_1 that is movable (by a fine-thread screw), where it is also reflected back. Upon its return, part of beam 1 passes through M_s and reaches the eye; and part of beam 2, on its return, is reflected by M_s into the eye. If the two path lengths are identical, the two coherent beams entering the eye constructively interfere and brightness will be seen. If the movable mirror is moved a distance $\lambda/4$, one beam will travel an extra distance equal to $\lambda/2$ (because it travels back and forth over the distance $\lambda/4$). In this case, the two beams will destructively interfere and darkness will be seen. As M_1 is moved farther, brightness will recur (when the path difference is λ), then darkness, and so on.

Very precise length measurements can be made with an interferometer. The motion of mirror M₁ by only $\frac{1}{4}\lambda$ produces a clear difference between brightness and darkness. For $\lambda = 400$ nm, this means a precision of 100 nm, or 10^{-4} mm! If mirror M_1 is tilted very slightly, the bright or dark spots are seen instead as a series of bright and dark lines or "fringes." By counting the number of fringes, or fractions thereof, extremely precise length measurements can be made.

24-10 Polarization

An important and useful property of light is that it can be *polarized*. To see what this means, let us examine waves traveling on a rope. A rope can be set into oscillation in a vertical plane as in Fig. 24-38a, or in a horizontal plane as in Fig. 24–38b. In either case, the wave is said to be **linearly polarized** or plane-polarized—that is, the oscillations are in a plane.

If we now place an obstacle containing a vertical slit in the path of the wave, Fig. 24–39, a vertically polarized wave passes through the vertical slit, but a horizontally polarized wave will not. If a horizontal slit were used, the vertically polarized wave would be stopped. If both types of slit were used, both types of wave would be stopped by one slit or the other. Note that polarization can exist *only* for transverse waves, and not for longitudinal waves such as sound. The latter oscillate only along the direction of motion, and neither orientation of slit would stop them.

FIGURE 24-39 Vertically polarized wave passes through a vertical slit, but a horizontally polarized wave will not.

FIGURE 24-40 Oscillation of the electric field vectors in unpolarized light. The light is traveling into or out of the page.

Maxwell's theory of light as electromagnetic (EM) waves predicted that light can be polarized since an EM wave is a transverse wave. The direction of polarization in a plane-polarized EM wave is taken as the direction of the electric field vector \vec{E} .

Light is not necessarily polarized. It can also be **unpolarized**, which means that the source has oscillations in many planes at once, as shown in Fig. 24–40. An ordinary incandescent lightbulb emits unpolarized light, as does the Sun.

[†]There are other types of interferometer, but Michelson's is the best known.

Polaroids

Plane-polarized light can be obtained from unpolarized light using certain crystals such as tourmaline. Or, more commonly today, we can use a Polaroid sheet. (Polaroid materials were invented in 1929 by Edwin Land.) A Polaroid sheet consists of complicated long molecules arranged parallel to one another. Such a Polaroid acts like a series of parallel slits to allow one orientation of polarization to pass through nearly undiminished. This direction is called the *transmission axis* of the Polaroid. A perpendicular polarization is absorbed almost completely by the Polaroid.

[Absorption by a Polaroid can be explained at the molecular level. An electric field \vec{E} that oscillates parallel to the long molecules can set electrons into motion along the molecules, thus doing work on them and transferring energy. Hence, if \vec{E} is parallel to the molecules, it gets absorbed. An electric field \vec{E} perpendicular to the long molecules does not have this possibility of doing work and transferring its energy, and so passes through freely. When we speak of the *transmission axis* of a Polaroid, we mean the direction for which \vec{E} is passed, so a Polaroid axis is *perpendicular* to the long molecules. If we want to think of there being slits between the parallel molecules in the sense of Fig. 24–39, then Fig. 24–39 would apply for the \vec{B} field in the EM wave, not the \vec{E} field.]

If a beam of plane-polarized light strikes a Polaroid whose transmission axis is at an angle θ to the incident polarization direction, the beam will emerge plane-polarized parallel to the Polaroid transmission axis, and the amplitude of E will be reduced to $E \cos \theta$, Fig. 24-41. Thus, a Polaroid passes only that component of polarization (the electric field vector, \vec{E}) that is parallel to its transmission axis. Because the intensity of a light beam is proportional to the square of the amplitude (Sections $11-10$ and $22-5$), we see that the intensity of a plane-polarized beam transmitted by a polarizer is

> $I = I_0 \cos^2 \theta$. $(24-5)$

Intensity of plane polarized wave reduced by polarizer

where I_0 is the incoming intensity and θ is the angle between the polarizer transmission axis and the plane of polarization of the incoming wave.[†]

A Polaroid can be used as a **polarizer** to produce plane-polarized light from unpolarized light, since only the component of light parallel to the axis is transmitted. A Polaroid can also be used as an analyzer to determine (1) if light is polarized and (2) the plane of polarization. A Polaroid acting as an analyzer will pass the same amount of light independent of the orientation of its axis if the light is unpolarized; try rotating one lens of a pair of Polaroid sunglasses while looking through it at a light bulb. If the light is polarized, however, when you rotate the Polaroid the transmitted light will be a maximum when the plane of polarization is parallel to the Polaroid's axis, and a minimum when perpendicular to it. If you do this while looking at the sky, preferably at right angles to the Sun's direction, you will see that skylight is polarized. (Direct sunlight is unpolarized, but don't look directly at the Sun, even through a polarizer, for damage to the eye may occur.) If the light transmitted by an analyzer Polaroid falls to zero at one orientation, then the light is 100% plane-polarized. If it merely reaches a minimum, the light is *partially polarized*.

 † Equation 24–5 is often referred to as **Malus' law**, after Etienne Malus, a contemporary of Fresnel.

FIGURE 24-42 Unpolarized light has equal intensity vertical and horizontal components. After passing through a polarizer, one of these components is eliminated. The intensity of the light is reduced to half.

> FIGURE 24-43 Crossed Polaroids completely eliminate light.

Unpolarized light consists of light with random directions of polarization. Each of these polarization directions can be resolved into components along two mutually perpendicular directions. On average, an unpolarized beam can be thought of as two plane-polarized beams of equal magnitude perpendicular to one another. When unpolarized light passes through a polarizer, one component is eliminated. So the intensity of the light passing through is reduced by half since half the light is eliminated: $I = \frac{1}{2}I_0$ (Fig. 24–42).

When two Polaroids are crossed—that is, their polarizing axes are perpendicular to one another—unpolarized light can be entirely stopped. As shown in Fig. 24–43, unpolarized light is made plane-polarized by the first Polaroid (the polarizer).

The second Polaroid, the analyzer, then eliminates this component since its transmission axis is perpendicular to the first. You can try this with Polaroid sunglasses (Fig. 24–44). Note that Polaroid sunglasses eliminate 50% of unpolarized light because of their polarizing property; they absorb even more because they are colored.

EXAMPLE 24-11 Two Polaroids at 60°. Unpolarized light passes through two Polaroids; the axis of one is vertical and that of the other is at 60° to the vertical. Describe the orientation and intensity of the transmitted light.

APPROACH Half of the unpolarized light is absorbed by the first Polaroid, and emerges plane polarized. When that light passes through the second Polaroid, the intensity is further reduced according to Eq. $24-5$, and the plane of polarization becomes along the axis of the second Polaroid.

SOLUTION The first Polaroid eliminates half the light, so the intensity is reduced by half: $I_1 = \frac{1}{2}I_0$. The light reaching the second polarizer is vertically polarized and so is reduced in intensity (Eq. $24-5$) to

$$
I_2 = I_1(\cos 60^\circ)^2 = \frac{1}{4}I_1.
$$

Thus, $I_2 = \frac{1}{8}I_0$. The transmitted light has an intensity one-eighth that of the original and is plane-polarized at a 60° angle to the vertical.

CONCEPTUAL EXAMPLE 24-12 Three Polaroids. We saw in Fig. 24-43 that when unpolarized light falls on two crossed Polaroids (axes at 90°), no light passes through. What happens if a third Polaroid, with axis at 45° to each of the other two, is placed between them (Fig. 24–45a)?

RESPONSE We start just as in Example 24–11 and recall again that light emerging from each Polaroid is polarized parallel to that Polaroid's axis. Thus the angle in Eq. 24–5 is that between the transmission axes of each pair of Polaroids taken in turn. The first Polaroid changes the unpolarized light to plane-polarized and reduces the intensity from I_0 to $I_1 = \frac{1}{2}I_0$. The second polarizer further reduces the intensity by $(\cos 45^\circ)^2$, Eq. 24–5:

$$
I_2 = I_1(\cos 45^\circ)^2 = \frac{1}{2}I_1 = \frac{1}{4}I_0.
$$

The light leaving the second polarizer is plane polarized at 45° (Fig. 24–45b) relative to the third polarizer, so the third one reduces the intensity to

$$
I_3 = I_2(\cos 45^\circ)^2 = \frac{1}{2}I_2,
$$

or $I_3 = \frac{1}{8}I_0$. Thus $\frac{1}{8}$ of the original intensity gets transmitted.

NOTE If we don't insert the 45° Polaroid, zero intensity results (Fig. 24–43).

EXERCISE E How much light would pass through if the 45° Polarizer in Example 24–12 was placed not between the other two polarizers but (a) before the vertical (first) polarizer, or (b) after the horizontal polarizer?

FIGURE 24-44 Crossed Polaroids. When the two polarized sunglass lenses overlap, with axes perpendicular, almost no light passes through.

Polarization by Reflection

Another means of producing polarized light from unpolarized light is by reflection. When light strikes a nonmetallic surface at any angle other than perpendicular, the reflected beam is polarized preferentially in the plane parallel to the surface, Fig. 24–46. In other words, the component with polarization in the plane perpendicular to the surface is preferentially transmitted or absorbed. You can check this by rotating Polaroid sunglasses while looking through them at a flat surface of a lake or road. Since most outdoor surfaces are horizontal, Polaroid sunglasses are made with their axes vertical to eliminate the more strongly reflected horizontal component, and thus reduce glare. People who go fishing wear Polaroids to eliminate reflected glare from the surface of a lake or stream and thus see beneath the water more clearly (Fig. 24–47).

FIGURE 24-46 Light reflected from a nonmetallic surface, such as the smooth surface of water in a lake, is partially polarized parallel to the surface.

FIGURE 24-47 Photographs of a river, (a) allowing all light into the camera lens, and (b) using a polarizer. The polarizer is adjusted to absorb most of the (polarized) light reflected from the water's surface, allowing the dimmer light from the bottom of the river, and any fish lying there, to be seen more readily.

The amount of polarization in the reflected beam depends on the angle, varying from no polarization at normal incidence to 100% polarization at an angle known as the **polarizing angle**, θ_p .[†] This angle is related to the index of refraction of the two materials on either side of the boundary by the equation

$$
\tan \theta_p = \frac{n_2}{n_1},\tag{24-6a}
$$

where n_1 is the index of refraction of the material in which the beam is traveling, and n_2 is that of the medium beyond the reflecting boundary. If the beam is traveling in air, $n_1 = 1$, and Eq. 24–6a becomes

The polarizing angle θ_p is also called **Brewster's angle**, and Eqs. 24–6 *Brewster's*

 law , after the Scottish physicist David Brewster (1781–1868), who worked it out experimentally in 1812. Equations 24–6 can be derived from the electromagnetic wave theory of light. It is interesting that at Brewster's angle, the reflected ray and the transmitted (refracted) ray make a 90° angle to each other; that is, $\theta_p + \theta_r = 90^\circ$, where θ_r is the refraction angle (Fig. 24-48). This can be seen by substituting Eq. 24–6a, $n_2 = n_1 \tan \theta_p = n_1 \sin \theta_p / \cos \theta_p$, into Snell's law, $n_1 \sin \theta_p = n_2 \sin \theta_r$, and get $\cos \theta_p = \sin \theta_r$ which can only

$$
an \theta_p = n.
$$

hold if $\theta_p = 90^\circ - \theta_r$.

 $(24-6b)$

FIGURE 24–48 At θ_p the reflected light is plane-polarized parallel to the surface, and $\theta_p + \theta_r = 90^\circ$, where θ_r is the refraction angle. (The large dots represent vibrations perpendicular to the page.)

EXAMPLE 24-13 Polarizing angle. (a) At what incident angle is sunlight reflected from a lake plane-polarized? (b) What is the refraction angle?

APPROACH The polarizing angle at the surface is Brewster's angle, Eq. 24–6b. We find the angle of refraction from Snell's law.

SOLUTION (a) We use Eq. 24–6b with $n = 1.33$, so $\tan \theta_p = 1.33$ giving $\theta_p = 53.1^\circ$. (b) From Snell's law, $\sin \theta_r = \sin \theta_p / n = \sin 53.1^\circ / 1.33 = 0.601$ giving $\theta_r = 36.9^\circ$. **NOTE** $\theta_p + \theta_r = 53.1^{\circ} + 36.9^{\circ} = 90.0^{\circ}$, as expected.

[†]Only a fraction of the incident light is reflected at the surface of a transparent medium. Although this reflected light is 100% polarized (if $\theta = \theta_p$), the remainder of the light, which is transmitted into the new medium, is only partially polarized.

FIGURE 24-49 Example of an image made up of many small squares or *pixels* (picture elements). This one has rather poor resolution.

FIGURE 24-50 Liquid crystal molecules tend to align in one dimension (parallel to each other) but have random positions (left-right, up-down).

FIGURE 24-51 (a) "Twisted" form of liquid crystal. Light polarization plane is rotated 90°. Only one line of molecules is shown. (b) Molecules disoriented by electric field. Plane of polarization is not changed, so light does not pass through the horizontal polarizer. (The transparent electrodes are not shown.)

24-11 Liquid Crystal Displays (LCD)

A wonderful use of polarization is in a liquid crystal display (LCD). LCDs are used as the display in hand-held calculators, digital wrist watches, cell phones, and in beautiful color flat-panel computer and television screens.

A liquid crystal display is made up of many tiny rectangles called **pixels**, or "picture elements." The picture you see depends on which pixels are dark or light and of what color, as suggested in Fig. 24-49 for a simple black and white picture.

Liquid crystals are organic materials that at room temperature exist in a phase that is neither fully solid nor fully liquid. They are sort of gooey, and their molecules display a randomness of position characteristic of liquids, as we discussed in Section 13–1 and Fig. 13–2. They also show some of the orderliness of a solid crystal (Fig. 13–2a), but only in one dimension. The liquid crystals we find useful are made up of relatively rigid rod-like molecules that interact weakly with each other and tend to align parallel to each other, as shown in Fig. 24-50.

In a simple LCD, each pixel (picture element) contains a liquid crystal sandwiched between two glass plates whose inner surfaces have been brushed to form nanometer-wide parallel scratches. The rod-like liquid crystal molecules in contact with the scratches tend to line up along the scratches. The two plates typically have their scratches at 90° to each other, and the weak forces between the rod-like molecules tend to keep them nearly aligned with their nearest neighbors, resulting in the twisted pattern shown in Fig. $24-51a$.

The outer surfaces of the glass plates each have a thin film polarizer, they too oriented at 90° to each other. Unpolarized light incident from the left becomes plane-polarized and the liquid crystal molecules keep this polarization aligned with their rod-like shape. That is, the plane of polarization of the light rotates with the molecules as the light passes through the liquid crystal. The light emerges with its plane of polarization rotated by 90°, and passes through the second polarizer readily. A tiny LCD pixel in this situation will appear bright.

Now suppose a voltage is applied to transparent electrodes on each glass plate of the pixel. The rod-like molecules are polar (or can acquire an internal separation of charge due to the applied electric field). The applied voltage tends to align the molecules and they no longer follow the twisted pattern shown in Fig. 24–51a, with the end molecules always lying in a plane parallel to the glass plates. Now the applied electric field tends to align the molecules flat, left to right (perpendicular to the glass plates), and they don't affect the light polarization significantly. The entering plane-polarized light no longer has its plane of polarization rotated as it passes through, and no light can exit through the second (horizontal) polarizer. With the voltage on, the pixel appears dark.[†]

[†]In some displays, the polarizers are parallel to each other (the scratches remain at 90° to maintain the twist). Then voltage off results in black (no light), and voltage on results in bright light.

CHAPTER 24 The Wave Nature of Light 688

The simple display screens of watches and calculators use ambient light as the source (you can't see the display in the dark), and a mirror behind the LCD to reflect the light back. There are only a few pixels, corresponding to the elongated segments needed to form the numbers from θ to θ (and letters in some displays), as seen in Fig. 24–52. Any pixels to which a voltage is applied appear dark and form part of a number. With no voltage, pixels pass light through the polarizers to the mirror and back out, which forms a bright background to the dark numbers on the display.

Color television and computer LCDs are more sophisticated. A color pixel consists of three cells, or subpixels, each covered with a red, green, or blue filter. Varying brightnesses of these three primary colors can yield almost any natural color. A good-quality screen consists of a million or more pixels, much like the surface of a color CRT monitor (Fig. 17-20). Behind this array of pixels is a light source, often thin fluorescent tubes the diameter of a straw. The light passes through the pixels, or not, depending on the voltage applied to each subpixel, as in Fig. 24–51a and b. See Fig. 24–53.

FIGURE 24-52 Calculator LCD display. The black segments or pixels have a voltage applied to them. Note that the 8 uses all seven segments (pixels), whereas other numbers use fewer.

FIGURE 24-53 Basic layer construction for an LCD computer or television screen. Every pixel contains three cells (subpixels), each with a red, green, or blue filter. An active matrix display has thin-film transistors and is more complex.

In a passive matrix LCD, a set of vertical and a set of horizontal electrodes carry electric signals to the pixels: two wires, one from each set, "intersect" at each subpixel, and careful electronic timing (called "addressing") turns the voltage there on or off. The signals can affect nearby subpixels, reducing the contrast and quality of the picture. Better pictures are obtained with an *active matrix* LCD which has a thin-film transistor (TFT) at each subpixel to accurately control its brightness.

To obtain a range of gray scale or range of color brightness, each subpixel cannot simply go on or off as in Fig. 24–51. Several techniques can be used depending on the construction of the LCD. If the voltage applied in Fig. 24–51b is small enough, the disorientation of the molecules may be small, allowing some rotation of the polarization vector and thus some light can pass through, the actual amount depending on the voltage. Alternatively, each subpixel can be pulsed—the length of time it is on affects the perceived brightness. The effect of stronger or weaker brightness can instead be provided by the number of nearby subpixels of the same color that are turned on or off; this type lets the eye "average" over many pixels, but reduces the sharpness or resolution of the picture.

FIGURE 24-54 Unpolarized sunlight scattered by molecules of the air. An observer at right angles sees plane-polarized light, since the component of oscillation along the line of sight emits no light along that line.

PHYSICS APPLIED Why the sky is blue Why sunsets are red

24-12 Scattering of Light by the Atmosphere

Sunsets are red, the sky is blue, and skylight is polarized (at least partially). These phenomena can be explained on the basis of the *scattering* of light by the molecules of the atmosphere. In Fig. 24–54 we see unpolarized light from the Sun impinging on a molecule of the Earth's atmosphere. The electric field of the EM wave sets the electric charges within the molecule into motion, and the molecule absorbs some of the incident radiation. But it quickly reemits this light since the charges are oscillating. As discussed in Section 22–2, oscillating electric charges produce EM waves. The intensity is strongest along a line perpendicular to the oscillation, and drops to zero along the line of oscillation (Section $22-2$). In Fig. 24–54 the motion of the charges is resolved into two components. An observer at right angles to the direction of the sunlight, as shown, will see planepolarized light because no light is emitted along the line of the other component of the oscillation. (When viewing along the line of an oscillation, you don't see that oscillation, and hence see no waves made by it.) At other viewing angles, both components will be present; one will be stronger, however, so the light appears partially polarized. Thus, the process of scattering explains the polarization of skylight.

Scattering of light by the Earth's atmosphere depends on λ . For particles much smaller than the wavelength of light (such as molecules of air), the particles will be less of an obstruction to long wavelengths than to short ones. The scattering decreases, in fact, as $1/\lambda^4$. Blue and violet light are thus scattered much more than red and orange, which is why the sky looks blue. At sunset, the Sun's rays pass through a maximum length of atmosphere. Much of the blue has been taken out by scattering. The light that reaches the surface of the Earth, and reflects off clouds and haze, is thus lacking in blue. That is why sunsets appear reddish.

The dependence of scattering on $1/\lambda^4$ is valid only if the scattering objects are much smaller than the wavelength of the light. This is valid for oxygen and nitrogen molecules whose diameters are about 0.2 nm. Clouds, however, contain water droplets or crystals that are much larger than λ . They scatter all frequencies of light nearly uniformly. Hence clouds appear white (or gray, if shadowed).

Why clouds are white

Summary

The wave theory of light is strongly supported by the observations that light exhibits interference and diffraction. Wave theory also explains the refraction of light and the fact that light travels more slowly in transparent solids and liquids than it does in air.

An aid to predicting wave behavior is Huygens' principle, which states that every point on a wave front can be considered as a source of tiny wavelets that spread out in the forward direction at the speed of the wave itself. The new wave front is the envelope (the common tangent) of all the wavelets.

The wavelength of light in a medium with index of refraction n is

$$
\lambda_n = \frac{\lambda}{n},\tag{24-1}
$$

where λ is the wavelength in vacuum; the frequency is not changed.

Young's double-slit experiment clearly demonstrated the interference of light. The observed bright spots of the interference pattern were explained as constructive interference between the beams coming through the two slits, where the beams differ in path length by an integral number of wavelengths. The dark areas in between are due to destructive interference when the path lengths differ by $\frac{1}{2}\lambda$, $\frac{3}{2}\lambda$, and so on. The angles θ at which **constructive interference** occurs are given by

$$
\sin \theta = m \frac{\lambda}{d},\tag{24-2a}
$$

where λ is the wavelength of the light, d is the separation of the slits, and m is an integer $(0, 1, 2, \dots)$. **Destructive interference** occurs at angles θ given by

$$
\sin \theta = \left(m + \frac{1}{2}\right)\frac{\lambda}{d},\tag{24-2b}
$$

where *m* is an integer $(0, 1, 2, \dots)$.

Two sources of light are perfectly coherent if the waves leaving them are of the same single frequency and maintain the same phase relationship at all times. If the light waves from the two sources have a random phase with respect to each other over time (as for two incandescent lightbulbs) the two sources are incoherent.

The frequency or wavelength of light determines its color. The visible spectrum extends from about 400 nm (violet) to about 750 nm (red).

Glass prisms break down white light into its constituent colors because the index of refraction varies with wavelength, a phenomenon known as dispersion.

The formula $\sin \theta = m\lambda/d$ for constructive interference also holds for a diffraction grating, which consists of many parallel slits or lines, separated from each other by a distance d . The peaks of constructive interference are much brighter and sharper for a diffraction grating than for the simple two-slit apparatus.

A diffraction grating (or a prism) is used in a spectroscope to separate different colors or to observe line spectra; for a given order m, θ depends on λ . Precise determination of wavelength can be done with a spectroscope by careful measurement of θ .

Diffraction refers to the fact that light, like other waves, bends around objects it passes, and spreads out after passing through narrow slits. This bending gives rise to a diffraction pattern due to interference between rays of light that travel different distances.

Light passing through a very narrow slit of width D (on the order of the wavelength λ) will produce a pattern with a bright central maximum of half-width θ given by

$$
\sin \theta = \frac{\lambda}{D},\tag{24-3a}
$$

flanked by fainter lines to either side.

Light reflected from the front and rear surfaces of a thin film of transparent material can interfere. A phase change of 180° ($\frac{1}{2}\lambda$) occurs when the light reflects at a surface where the

Questions

- 1. Does Huygens' principle apply to sound waves? To water waves? Explain.
- 2. What is the evidence that light is energy?
- 3. Why is light sometimes described as rays and sometimes as waves?
- 4. We can hear sounds around corners, but we cannot see around corners; yet both sound and light are waves. Explain the difference.
- 5. If Young's double-slit experiment were submerged in water, how would the fringe pattern be changed?
- 6. Monochromatic red light is incident on a double slit, and the interference pattern is viewed on a screen some distance away. Explain how the fringe pattern would change if the red light source is replaced by a blue light source.
- 7. Two rays of light from the same source destructively interfere if their path lengths differ by how much?
- 8. Why was the observation of the double-slit interference pattern more convincing evidence for the wave theory of light than the observation of diffraction?
- 9. Compare a double-slit experiment for sound waves to that for light waves. Discuss the similarities and differences.
- 10. Why doesn't the light from the two headlights of a distant car produce an interference pattern?
- 11. Suppose white light falls on the two slits of Fig. 24–7, but one slit is covered by a red filter (700 nm) and the other by a blue filter (450 nm). Describe the pattern on the screen.
- 12. When white light passes through a flat piece of window glass, it is not broken down into colors as it is by a prism. Explain.
- 13. For both converging and diverging lenses, discuss how the focal length for red light differs from that for violet light.

index of refraction increases. Such thin-film interference has many practical applications, such as lens coatings and Newton's rings.

In unpolarized light, the electric field vectors oscillate in all transverse directions. If the electric vector oscillates only in one plane, the light is said to be **plane-polarized**. Light can also be partially polarized.

When an unpolarized light beam passes through a Polaroid sheet, the emerging beam is plane-polarized. When a light beam is polarized and passes through a Polaroid, the intensity varies as the Polaroid is rotated. Thus a Polaroid can act as a polarizer or as an analyzer.

The intensity of a plane-polarized light beam incident on a Polaroid is reduced by the factor

$$
I = I_0 \cos^2 \theta, \tag{24-5}
$$

where θ is the angle between the axis of the Polaroid and the initial plane of polarization.

Light can also be partially or fully polarized by reflection. If light traveling in air is reflected from a medium of index of refraction n , the reflected beam will be *completely* planepolarized if the incident angle θ_p is given by

$$
\tan \theta_{\rm p} = n. \tag{24-6b}
$$

The fact that light can be polarized shows that it must be a transverse wave.

14. A ray of light is refracted through three different materials (Fig. 24–55). Rank the materials according to their index of refraction, least to greatest.

FIGURE 24-55 Question 14.

- 15. Hold one hand close to your eye and focus on a distant light source through a narrow slit between two fingers. (Adjust your fingers to obtain the best pattern.) Describe the pattern that you see.
- 16. What happens to the diffraction pattern of a single slit if the whole apparatus is immersed in (a) water, (b) a vacuum, instead of in air.
- 17. For diffraction by a single slit, what is the effect of increasing (a) the slit width, and (b) the wavelength?
- 18. What is the difference in the interference patterns formed (a) by two slits 10^{-4} cm apart, (b) by a diffraction grating containing 10⁴ lines/cm?
- 19. For a diffraction grating, what is the advantage of (a) many slits, (b) closely spaced slits?
- **20.** White light strikes (a) a diffraction grating, and (b) a prism. A rainbow appears on a wall just below the direction of the horizontal incident beam in each case. What is the color of the top of the rainbow in each case? Explain.
- 21. For light consisting of wavelengths between 400 nm and 700 nm, incident normally on a diffraction grating, for what orders (if any) would there be overlap in the observed spectrum? Does your answer depend on the slit spacing?
- 22. Why are interference fringes noticeable only for a *thin* film like a soap bubble and not for a thick piece of glass, say?

23. When a compact disk (CD) is held at an angle in white light, the reflected light is a full spectrum (Fig. 24-56). Explain. What would you expect to see if monochromatic light was used?

FIGURE 24-56 Question 23.

- 24. Why are Newton's rings (Fig. 24-31) closer together farther from the center?
	- **Problems**

24-3 Double-Slit Interference

- 1. (I) Monochromatic light falling on two slits 0.016 mm apart produces the fifth-order fringe at an 8.8° angle. What is the wavelength of the light used?
- 2. (I) The third-order fringe of 610 nm light is observed at an angle of 18° when the light falls on two narrow slits. How far apart are the slits?
- 3. (II) Monochromatic light falls on two very narrow slits 0.048 mm apart. Successive fringes on a screen 5.00 m away are 6.5 cm apart near the center of the pattern. Determine the wavelength and frequency of the light.
- 4. (II) A parallel beam of light from a He-Ne laser, with a wavelength 656 nm, falls on two very narrow slits 0.060 mm apart. How far apart are the fringes in the center of the pattern on a screen 3.6 m away?
- 5. (II) Light of wavelength 680 nm falls on two slits and produces an interference pattern in which the fourthorder fringe is 38 mm from the central fringe on a screen 2.0 m away. What is the separation of the two slits?
- 6. (II) If 720-nm and 660-nm light passes through two slits 0.58 mm apart, how far apart are the second-order fringes for these two wavelengths on a screen 1.0 m away?
- 7. (II) In a double-slit experiment, it is found that blue light of wavelength 460 nm gives a second-order maximum at a certain location on the screen. What wavelength of visible light would have a minimum at the same location?
- 8. (II) Water waves having parallel crests 2.5 cm apart pass through two openings 5.0 cm apart in a board. At a point 2.0 m beyond the board, at what angle relative to the "straight-through" direction would there be little or no wave action?
- 692 CHAPTER 24 The Wave Nature of Light
- 25. Some coated lenses appear greenish yellow when seen by reflected light. What wavelengths do you suppose the coating is designed to transmit completely?
- 26. A drop of oil on a pond appears bright at its edges, where its thickness is much less than the wavelengths of visible light. What can you say about the index of refraction of the oil?
- 27. What does polarization tell us about the nature of light?
- 28. Explain the advantage of polarized sunglasses over normal tinted sunglasses.
- 29. How can you tell if a pair of sunglasses is polarizing or not?
- 30. Two polarized sheets rotated at an angle of 90° with respect to each other will not let any light through. Three polarized sheets, each rotated at an angle of 45° with respect to each other, will let some light through. What will happen to unpolarized light if you align four polarized sheets, each rotated at an angle of 30° with respect to the one in front of it?
- *31. What would be the color of the sky if the Earth had no atmosphere?
- *32. If the Earth's atmosphere were 50 times denser than it is, would sunlight still be white, or would it be some other color?

9. (II) Suppose a thin piece of glass is placed in front of the lower slit in Fig. 24-7 so that the two waves enter the slits 180° out of phase (Fig. 24-57). Describe in detail the interference pattern on the screen.

> **FIGURE 24-57** Problem 9.

- 10. (II) In a double-slit experiment, the third-order maximum for light of wavelength 500 nm is located 12 mm from the central bright spot on a screen 1.6 m from the slits. Light of wavelength 650 nm is then projected through the same slits. How far from the central bright spot will the secondorder maximum of this light be located?
- 11. (II) Two narrow slits separated by 1.0 mm are illuminated by 544 nm light. Find the distance between adjacent bright fringes on a screen 5.0 m from the slits.
- 12. (III) Light of wavelength 480 nm in air falls on two slits 6.00×10^{-2} mm apart. The slits are immersed in water, as is a viewing screen 40.0 cm away. How far apart are the fringes on the screen?
- 13. (III) A very thin sheet of plastic ($n = 1.60$) covers one slit of a double-slit apparatus illuminated by 640-nm light. The center point on the screen, instead of being a maximum, is dark. What is the (minimum) thickness of the plastic?

24-4 Dispersion

- 14. (I) By what percent, approximately, does the speed of red light (700 nm) exceed that of violet light (400 nm) in silicate flint glass? (See Fig. 24–14.)
- **15.** (II) A light beam strikes a piece of glass at a 60.00° incident angle. The beam contains two wavelengths, 450.0 nm and 700.0 nm, for which the index of refraction of the glass is 1.4820 and 1.4742, respectively. What is the angle between the two refracted beams?

16. (III) A parallel beam of light containing two wavelengths, λ_1 = 450 nm and λ_2 = 650 nm, enters the silicate flint glass of an equilateral prism as shown in Fig. 24-58. At what angle does each beam leave the prism (give angle with normal to the face)?

Problems 16 and 87. 24-5 Single-Slit Diffraction

FIGURE 24-58

- 17. (I) If 580-nm light falls on a slit 0.0440 mm wide, what is the full angular width of the central diffraction peak?
- **18.** (I) Monochromatic light falls on a slit that is 2.60×10^{-3} mm wide. If the angle between the first dark fringes on either side of the central maximum is 35.0° (dark fringe to dark fringe), what is the wavelength of the light used?
- 19. (II) Light of wavelength 520 nm falls on a slit that is 3.20×10^{-3} mm wide. Estimate how far the first brightish diffraction fringe is from the strong central maximum if the screen is 10.0 m away.
- 20. (II) A single slit 1.0 mm wide is illuminated by 450-nm light. What is the width of the central maximum (in cm) in the diffraction pattern on a screen 5.0 m away?
- 21. (II) Monochromatic light of wavelength 653 nm falls on a slit. If the angle between the first bright fringes on either side of the central maximum is 32°, estimate the slit width.
- 22. (II) How wide is the central diffraction peak on a screen 2.30 m behind a 0.0348-mm-wide slit illuminated by 589-nm light?
- 23. (II) When blue light of wavelength 440 nm falls on a single slit, the first dark bands on either side of center are separated by 55.0°. Determine the width of the slit.
- 24. (II) When violet light of wavelength 415 nm falls on a single slit, it creates a central diffraction peak that is 9.20 cm wide on a screen that is 2.55 m away. How wide is the slit?
- 25. (II) If a slit diffracts 650-nm light so that the diffraction maximum is 4.0 cm wide on a screen 1.50 m away, what will be the width of the diffraction maximum for light of wavelength 420 nm?
- **26.** (II) For a given wavelength λ , what is the maximum slit width for which there will be no diffraction minima?

24-6 and 24-7 Gratings

- 27. (I) At what angle will 560-nm light produce a secondorder maximum when falling on a grating whose slits are 1.45×10^{-3} cm apart?
- 28. (I) A 3500-line/cm grating produces a third-order fringe at a 28.0° angle. What wavelength of light is being used?
- 29. (II) How many lines per centimeter does a grating have if the third-order occurs at an 18.0° angle for 630-nm light?
- 30. (II) A grating has 8300 lines/cm. How many complete spectral orders can be seen (400 nm to 700 nm) when it is illuminated by white light?
- 31. (II) The first-order line of 589-nm light falling on a diffraction grating is observed at a 15.5° angle. How far apart are the slits? At what angle will the third order be observed?
- 32. (II) A diffraction grating has 6.0×10^5 lines/m. Find the angular spread in the second-order spectrum between red light of wavelength 7.0×10^{-7} m and blue light of wavelength 4.5×10^{-7} m.
- 33. (II) Light falling normally on a 9700-line/cm grating is revealed to contain three lines in the first-order spectrum at angles of 31.2°, 36.4°, and 47.5°. What wavelengths are these?
- 34. (II) What is the highest spectral order that can be seen if a grating with 6000 lines per cm is illuminated with 633-nm laser light? Assume normal incidence.
- 35. (II) Two (and only two) full spectral orders can be seen on either side of the central maximum when white light is sent through a diffraction grating. What is the maximum number of lines per cm for the grating?
- 36. (II) White light containing wavelengths from 410 nm to 750 nm falls on a grating with 8500 lines/cm. How wide is the first-order spectrum on a screen 2.30 m away?
- 37. (II) A He-Ne gas laser which produces monochromatic light of a known wavelength $\lambda = 6.328 \times 10^{-7}$ m is used to calibrate a reflection grating in a spectroscope. The first-order diffraction line is found at an angle of 21.5° to the incident beam. How many lines per meter are there on the grating?
- 38. (II) Two first-order spectrum lines are measured by a 9500-line/cm spectroscope at angles, on each side of center, of $+26^{\circ}38'$, $+41^{\circ}08'$ and $-26^{\circ}48'$, $-41^{\circ}19'$. What are the wavelengths?

24-8 Thin-Film Interference

- 39. (I) If a soap bubble is 120 nm thick, what wavelength is most strongly reflected at the center of the outer surface when illuminated normally by white light? Assume that $n = 1.34$.
- $40.$ (I) How far apart are the dark fringes in Example 24–8 if the glass plates are each 26.5 cm long?
- 41. (II) What is the smallest thickness of a soap film $(n = 1.42)$ that would appear black if illuminated with 480-nm light? Assume there is air on both sides of the soap film.
- 42. (II) A lens appears greenish yellow $(\lambda = 570 \text{ nm})$ is strongest) when white light reflects from it. What minimum thickness of coating ($n = 1.25$) do you think is used on such a glass ($n = 1.52$) lens, and why?
- 43. (II) A total of 31 bright and 31 dark Newton's rings (not counting the dark spot at the center) are observed when 550-nm light falls normally on a planoconvex lens resting on a flat glass surface (Fig. 24–31). How much thicker is the center than the edges?
- 44. (II) A fine metal foil separates one end of two pieces of optically flat glass, as in Fig. 24-33. When light of wavelength 670 nm is incident normally, 28 dark lines are observed (with one at each end). How thick is the foil?
- 45. (II) How thick (minimum) should the air layer be between two flat glass surfaces if the glass is to appear bright when 450-nm light is incident normally? What if the glass is to appear dark?
- 46. (II) A piece of material, suspected of being a stolen diamond $(n = 2.42)$, is submerged in oil of refractive index 1.43 and illuminated by unpolarized light. It is found that the reflected light is completely polarized at an angle of 59°. Is it diamond?
- 47. (III) A thin film of alcohol ($n = 1.36$) lies on a flat glass plate ($n = 1.51$). When monochromatic light, whose wavelength can be changed, is incident normally, the reflected light is a minimum for $\lambda = 512$ nm and a maximum for $\lambda = 640$ nm. What is the minimum thickness of the film?

48. (III) When a Newton's ring apparatus (Fig. $24-31$) is immersed in a liquid, the diameter of the eighth dark ring decreases from 2.92 cm to 2.48 cm. What is the refractive index of the liquid?

* 24-9 Michelson Interferometer

- * 49. (II) What is the wavelength of the light entering an interferometer if 644 bright fringes are counted when the movable mirror moves 0.225 mm?
- * 50. (II) A micrometer is connected to the movable mirror of an interferometer. When the micrometer is tightened down on a thin metal foil, the net number of bright fringes that move, compared to the empty micrometer, is 272. What is the thickness of the foil? The wavelength of light used is 589 nm.
- $*$ 51. (II) How far must the mirror M_1 in a Michelson interferometer be moved if 850 fringes of 589-nm light are to pass by a reference line?
- * 52. (III) One of the beams of an interferometer (Fig. 24-59) passes through a small glass container containing a cavity 1.30 cm deep. When a gas is allowed to slowly fill the container, a total of 236 dark fringes are counted to move past a reference line. The light used has a wavelength of 610 nm. Calculate the index of refraction of the gas, assuming that the interferometer is in vacuum.

FIGURE 24-59 Problem 52.

General Problems

- 62. Light of wavelength 5.0×10^{-7} m passes through two parallel slits and falls on a screen 4.0 m away. Adjacent bright bands of the interference pattern are 2.0 cm apart. (a) Find the distance between the slits (b) The same two slits are next illuminated by light of a different wavelength, and the fifth-order minimum for this light occurs at the same point on the screen as the fourth-order minimum for the previous light. What is the wavelength of the second source of light?
- 63. Television and radio waves reflecting from mountains or airplanes can interfere with the direct signal from the station. (a) What kind of interference will occur when 75-MHz television signals arrive at a receiver directly from a distant station, and are reflected from a nearby airplane 118 m directly above the receiver? Assume $\frac{1}{2}\lambda$ change in phase of the signal upon reflection. (b) What kind of interference will occur if the plane is 22 m closer to the receiver?
- 64. Red light from three separate sources passes through a diffraction grating with 3.00×10^5 lines/m. The wavelengths of the three lines are 6.56×10^{-7} m (hydrogen), 6.50×10^{-7} m (neon), and 6.97×10^{-7} m (argon). Calculate the angles for the first-order diffraction lines of each of these sources.

24-10 Polarization

- 53. (I) Two polarizers are oriented at 65° to one another. Unpolarized light falls on them. What fraction of the light intensity is transmitted?
- 54. (I) What is Brewster's angle for an air-glass $(n = 1.52)$ surface?
- 55. (II) What is Brewster's angle for a diamond submerged in water if the light is hitting the diamond ($n = 2.42$) while traveling in the water?
- 56. (II) Two Polaroids are aligned so that the light passing through them is a maximum. At what angle should one of them be placed so that the intensity is subsequently reduced by half?
- 57. (II) At what angle should the axes of two Polaroids be placed so as to reduce the intensity of the incident unpolarized light to $(a) \frac{1}{3}$, $(b) \frac{1}{10}$?
- 58. (II) Two polarizers are oriented at 40° to each other and plane-polarized light is incident on them. If only 15% of the light gets through both of them, what was the initial polarization direction of the incident light?
- 59. (II) Two polarizers are oriented at 38.0° to one another. Light polarized at a 19.0° angle to each polarizer passes through both. What percent reduction in intensity takes place?
- 60. (II) What would Brewster's angle be for reflections off the surface of water for light coming from beneath the surface? Compare to the angle for total internal reflection, and to Brewster's angle from above the surface.
- 61. (II) Unpolarized light passes through five successive Polaroid sheets, each of whose axis makes a 45° angle with the previous one. What is the intensity of the transmitted beam?
- 65. Light of wavelength 590 nm passes through two narrow slits 0.60 mm apart. The screen is 1.70 m away. A second source of unknown wavelength produces its second-order fringe 1.33 mm closer to the central maximum than the 590-nm light. What is the wavelength of the unknown light?
- 66. A radio station operating at 102.1 MHz broadcasts from two identical antennae at the same elevation but separated by an 8.0-m horizontal distance d , Fig. 24-60. A maximum signal is found along the midline, perpendicular to d at its midpoint and extending horizontally in both directions. If the midline is taken as 0° , at what other angle(s) θ is a maximum signal detected? A minimum signal? Assume all measurements are made much farther than 8.0 m from the antenna towers.

FIGURE 24-60 Problem 66.
- 67. A teacher stands well back from an outside doorway 0.88 m wide, and blows a whistle of frequency 750 Hz. Ignoring reflections, estimate at what angle(s) it is *not* possible to hear the whistle clearly on the playground outside the doorway.
- 68. If parallel light falls on a single slit of width D at a 30 $^{\circ}$ angle to the normal, describe the diffraction pattern.
- 69. The wings of a certain beetle have a series of parallel lines across them. When normally incident 460-nm light is reflected from the wing, the wing appears bright when viewed at an angle of 51°. How far apart are the lines?
- 70. How many lines per centimeter must a grating have if there is to be no second-order spectrum for any visible wavelength?
- 71. Show that the second- and third-order spectra of white light produced by a diffraction grating always overlap. What wavelengths overlap exactly?
- 72. When yellow sodium light, $\lambda = 589$ nm, falls on a diffraction grating, its first-order peak on a screen 60.0 cm away falls 3.32 cm from the central peak. Another source produces a line 3.71 cm from the central peak. What is the wavelength of the new source? How many lines/cm are on the grating?
- 73. Light is incident on a diffraction grating with 8600 lines/cm, and the pattern is viewed on a screen 2.5 m from the grating. The incident light beam consists of two wavelengths, $\lambda_1 = 4.6 \times 10^{-7}$ m and $\lambda_2 = 6.8 \times 10^{-7}$ m. Calculate the linear distance between the first-order bright fringes of these two wavelengths on the screen.
- 74. What is the index of refraction of a clear material if a minimum of 150 nm thickness of it, when laid on glass, is needed to reduce reflection to nearly zero when light of 600 nm is incident normally upon it? Do you have a choice for an answer?
- 75. Monochromatic light of variable wavelength is incident normally on a thin sheet of plastic film in air. The reflected light is a minimum only for $\lambda = 512$ nm and $\lambda = 640$ nm in the visible spectrum. What is the thickness of the film $(n = 1.58)$? [*Hint*: assume successive values of m.]
- 76. Compare the minimum thickness needed for an antireflective coating ($n = 1.38$) applied to a glass lens in order to eliminate (a) blue (450 nm) , or (b) red (700 nm) reflections for light at normal incidence.
- 77. What is the minimum (non-zero) thickness for the air layer between two flat glass surfaces if the glass is to appear dark when 640-nm light is incident normally? What if the glass is to appear bright?
- 78. Suppose you viewed the light *transmitted* through a thin film layered on a flat piece of glass. Draw a diagram, similar to Fig. 24-30 or 24-36, and describe the conditions required for maxima and minima. Consider all possible values of index of refraction. Discuss the relative size of the minima compared to the maxima and to zero.
- 79. At what angle above the horizon is the Sun when light reflecting off a smooth lake is polarized most strongly?

Answers to Exercises

- $A: 2.5$ mm.
- B: Narrower.
- $C: 4900$ lines/cm.
- **D:** A.
- 80. At what angle should the axes of two Polaroids be placed so as to reduce the intensity of the incident unpolarized light by an additional factor (after the first Polaroid cuts it in half) of (a) 4, (b) 10, (c) 100?
- 81. Unpolarized light falls on two polarizer sheets whose transmission axes are at right angles. A third polarizer is placed between the first two so that its axis makes a 62° angle with the axis of the first polarizer. (a) What fraction of the incident light intensity is transmitted? (b) What if the third polarizer is in front of the other two?
- 82. Four polarizers are placed in succession with their axes vertical, at 30° to the vertical, at 60° to the vertical, and at 90 $^{\circ}$ to the vertical. (a) Calculate what fraction of the incident unpolarized light is transmitted by the four polarizers. (b) Can the transmitted light be *decreased* by removing one of the polarizers? If so, which one? (c) Can the transmitted light intensity be extinguished by removing polarizers? If so, which one(s)?
- 83. A laser beam passes through a slit of width 1.0 cm and is pointed at the Moon, which is approximately 380,000 km from the Earth. Assume the laser emits waves of wavelength 630 nm (the red light of a He-Ne laser). Estimate the width of the beam when it reaches the Moon.
- 84. A series of polarizers are each placed at a 10° interval from the previous polarizer. Unpolarized light is incident on this series of polarizers. How many polarizers does the light have to go through before it is $\frac{1}{4}$ of its original intensity?
- 85. A thin film of soap ($n = 1.34$) coats a piece of flat glass $(n = 1.52)$. How thick is the film if it reflects 643-nm red light most strongly when illuminated normally by white light?
- 86. Consider two antennas radiating 6.0-MHz radio waves in phase with each other. They are located at points S_1 and S_2 , separated by a distance $d = 175$ m, Fig. 24–61. What are the first three points on the y axis where the signals from the two sources will be out of phase (crests of one meet troughs of the other)?

- 87. A parallel beam of light containing two wavelengths, 420 nm and 650 nm, enters a silicate flint glass equilateral prism (Fig. $24-58$). (a) What is the angle between the two beams leaving the prism? (b) Repeat part (a) for a diffraction grating with 6200 lines/cm.
- * 88. A Lucite planoconvex lens has one flat surface and one with $R = 18.4$ cm. It is used to view an object, located 66.0 cm away from the lens, which is a mixture of red and yellow. The index of refraction of the Lucite is 1.5106 for red light and 1.5226 for yellow light. What are the locations of the red and yellow images formed by the lens? [*Hint*: see Section 23-10.]
- **E:** Zero for both (a) and (b) , because the two successive polarizers at 90° cancel all light. The 45° Polaroid must be inserted *between* the other two if transmission is to occur.

Of the many optical devices we discuss in this Chapter, the magnifying glass is the simplest. Here it is magnifying page 705 of this Chapter, which describes how the magnifying glass works according to the ray model. In this Chapter we also discuss film

and digital cameras, the human eve, telescopes, and microscopes, as well as image resolution, X-rays, and CT scans.

Comparison of part (a) of Fig. \geq ject is viewed at the near point with the the object subtends at the eye is much larger in which the same angular magnification or magnifying power, M , O . eals that the angle aifier is used. The of the angle subtended by an object when using the fined as the ratio using the unaided eye, with the object at the ngle subtended $(N = 25$ cm for a normal eve): V of the eve $M = \frac{\theta'}{a}$, $(25-1)$ where θ and θ' are shown in Fig. 25–16. We can write s of the focal Fig. 25-16a). length by noting that $\theta = h/N$ (Fig. 25–16b) and 6 small so θ and where h is the height of the object and we assume the ye strain), the θ' equal their sines and tangents. If the eye is relaxed

image will be at infinity and the object will be preci-Fig. 25–17. Then $d_0 = f$ and $\theta' = h/f$. Thus

Optical Instruments

CHAPTER

n our discussion of the behavior of light in the two previous Chapters, we also described a few instruments such as the spectrometer and the Michelson interferometer. In this Chapter, we will discuss some other, more common, instruments, most of which use lenses, such as the camera, telescope, microscope, and the human eye. To describe their operation, we will use ray diagrams. However, we will see that understanding some aspects of their operation will require the wave nature of light.

25-1 Cameras, Film and Digital

The basic elements of a camera are a lens, a light-tight box, a shutter to let light pass through the lens only briefly, and in a traditional camera a piece of film (Fig. $25-1$), or in a digital camera an electronic sensor. When the shutter is opened, light from external objects in the field of view is focused by the lens as an image on the film or sensor. Film contains light-sensitive chemicals that change when light strikes them. In the development process, chemical reactions cause the changed areas to turn opaque, so the image is recorded on the film.[†] You can see the image yourself if you remove the back of a conventional camera and view through a piece of tissue paper (on which an image can form) placed where the film should be with the shutter open.

Digital Cameras, CCD Sensors

In a digital camera, the film is replaced by a semiconductor sensor known as a **charge-coupled device (CCD).** A CCD sensor is made up of millions of tiny pixels ("picture elements")—see Fig. 24–49. A 3-MP (3-megapixel) sensor[†] would contain about 1500 pixels vertically by 2000 pixels horizontally over an area of perhaps $9 \text{ mm} \times 12 \text{ mm}$. Light reaching any pixel liberates electrons from the semiconductor. The more intense the light, the more charge accumulates during the brief exposure time. Conducting electrodes carry each pixel's charge (serially in time, row by row—hence the name "charge-coupled") to a central processor that stores the relative brightness of pixels, and allows reformation of the image later on a computer screen or printer.

A CCD is fully reusable. Once the pixel charges are transferred to memory, a new picture can be taken.

Color is achieved by red, green, and blue filters over alternating pixels as shown in Fig. 25-2, similar to a color CRT or LCD screen. The sensor type shown in Fig. $25-2$ contains twice as many green pixels as red or blue (green is claimed to have a stronger influence on the sensation of sharpness). The computer-analyzed color at each pixel is that pixel's intensity averaged with the intensities of the nearest-neighbor colors.

To reduce the amount of memory for each picture, compression programs can average over pixels, but with a consequent loss of sharpness, or "resolution."

* Digital Artifacts

Digital cameras can produce image artifacts (errors in the image not present in the original, resulting from the imaging process). One example using the "mosaic" pixels of Fig. $25-2$ is described in Fig. $25-3$. Another technology uses a semitransparent silicon semiconductor layer system, exploiting the fact that different wavelengths of light penetrate silicon to different depths: each pixel is a sandwich of partly transparent layers, one for each color. The top layer can absorb blue light, allowing green and red light to pass through. The second layer absorbs green and the bottom layer detects the red. All three colors are detected by each pixel, resulting in better color resolution and fewer artifacts.

[†]This is called a *negative*, because the black areas correspond to bright objects and vice versa. The same process occurs during printing to produce a black-and-white "positive" picture from the negative. Color film has three emulsion layers (or dyes) corresponding to the three primary colors. [‡]Each different color of pixel in a CCD is counted as a separate pixel. In contrast, in an LCD screen (Section 24-11), a group of three subpixels is counted as one pixel, a more conservative count.

FIGURE 25-3 Suppose we take a picture that includes a thin black line (our object) on a white background. The image of this black line has a colored halo (red above, blue below) due to the mosaic arrangement of color filter pixels, as shown by the colors transmitted. Computer averaging can minimize color problems such as this (the green at top and bottom of image can be averaged with nearby pixels to give white or nearly so) but the image is consequently "softened" or blurred. The layered color pixel described in the text would avoid this artifact.

FIGURE 25-2 Portion of a typical CCD sensor. A square group of four pixels $_{\rm GB}^{\rm RG}$ is sometimes called a "color pixel."

Camera Adjustments

There are three main adjustments on good-quality cameras: shutter speed, f-stop, and focusing. Although most cameras today make these adjustments automatically, it is valuable to understand these adjustments to use a camera effectively. For special or top-quality work, a manual camera is indispensable (Fig. 25–4).

Shutter speed This refers to how long the shutter is open and the film exposed. It may vary from a second or more ("time exposures") to $\frac{1}{1000}$ s or less. To avoid blurring from camera movement, speeds faster than $\frac{1}{100}$ s are normally used. If the object is moving, faster shutter speeds are needed to "stop" the action. A shutter can open and close "behind the lens," as in Fig. 25–1, or be a "focal plane" shutter which is a moveable curtain just in front of the film.

Digital cameras have "electronic shutters," which are the brief sampling times for collecting pixel charges; they may also have a mechanical shutter which is normally open so you can view the shot on the built-in LCD screen, but closes just before the shot is taken, opens briefly to shoot, and reopens afterward. Digital still cameras that take short movies must have a fast "sampling" time and a fast "clearing" (of the charge) time so as to take pictures of at least 12 or 15 frames per second.

f-stop The amount of light reaching the film must be carefully controlled to avoid **underexposure** (too little light so the picture is dark and only the brightest objects show up) or **overexposure** (too much light, so that all bright objects look the same, with a consequent lack of contrast and a "washed-out" appearance). To control the exposure, a "stop" or iris diaphragm, whose opening is of variable diameter, is placed behind the lens (Fig. $25-1$). The size of the opening is varied to compensate for bright or dark lighting conditions, the sensitivity of the film[†] used, and for different shutter speeds. The size of the opening is specified by the f -number or f -stop, defined as

$$
f\text{-stop} = \frac{f}{D}
$$

where f is the focal length of the lens and D is the diameter of the lens opening (Fig. 25–1). For example, when a 50-mm-focal-length lens has an opening $D = 25$ mm, we say it is set at $f/2$. When this lens is set at $f/8$, the opening is only $6\frac{1}{4}$ mm $(50/6\frac{1}{4} = 8)$. For faster shutter speeds, or low light conditions, a greater lens opening must be used to get a proper exposure. This corresponds to a smaller f-stop number. The smaller the f -stop number, the larger the opening and the more light passes through the lens to the film. The smallest f-number of a lens (largest opening) is referred to as the *speed* of the lens. It is common to find $f/2.0$ lenses today, and some even faster. The advantage of a fast lens is that it allows pictures to be taken under poor lighting conditions. Good quality lenses consist of several elements to reduce the defects present in simple thin lenses (Section 25-6). Standard f-stop markings on good lenses are 1.0, 1.4, 2.0, 2.8, 4.0, 5.6, 8, 11, 16, 22, and 32 (Fig. 25–4). Each of these stops corresponds to a diameter reduction by a factor of about $\sqrt{2}$ = 1.4. Because the amount of light reaching the film is proportional to the *area* of the opening, and therefore proportional to the diameter squared, each standard f-stop corresponds to a factor of 2 in light intensity reaching the film.

Focusing Focusing is the operation of placing the lens at the correct position **Focusing** relative to the film for the sharpest image. The image distance is smallest for objects at infinity (the symbol ∞ is used for infinity) and is equal to the focal length. For closer objects, the image distance is greater than the focal length, as can be seen from the lens equation, $1/f = 1/d_0 + 1/d_i$ (Eq. 23–8). To focus on nearby objects, the lens must therefore be moved away from the film, and this is usually done on a manual camera by turning a ring on the lens.

> [†]Different films have different sensitivities to light, referred to as the "film speed" and specified as an "ASA number" or "ISO number." A "faster" film is more sensitive and needs less light to produce a good image. Faster films are grainier so offer less sharpness (resolution) when enlarged. Digital cameras may have a "gain" or "ISO" adjustment for sensitivity. Adjusting a CCD to be "faster" for low light conditions results in "noise," the digital equivalent of graininess.

Digital camera shutter

FIGURE 25-4 On this camera, the f-stops and the focusing ring are on the camera lens. Shutter speeds are selected on the small wheel on top of the camera body. f -stop

If the lens is focused on a nearby object, a sharp image of it will be formed, but the image of distant objects may be blurry (Fig. $25-5$). The rays from a point on the distant object will be out of focus—they will form a circle on the film as shown (exaggerated) in Fig. 25–6. The distant object will thus produce an image consisting of overlapping circles and will be blurred. These circles are called circles of confusion. To include near and distant objects in the same photo, you can try setting the lens focus at an intermediate position. For a given distance setting, there is a range of distances over which the circles of confusion will be small enough that the images will be reasonably sharp. This is called the depth of field. The depth of field varies with the lens opening. If the lens opening is smaller, only rays through the central part of the lens are accepted, and these form smaller circles of confusion for a given object distance. Hence, at smaller lens openings, a greater range of object distances will fit within the circle of confusion criterion, so the depth of field is greater. For 35-mm cameras, the depth of field is based on a maximum circle of confusion diameter of 0.03 mm.

FIGURE 25-6 When the lens is positioned to focus on a nearby object, points on a distant object produce circles and are therefore blurred. (The effect is shown greatly exaggerated.)

Depth of field

EXAMPLE 25-1 Camera focus. How far must a 50.0-mm-focal-length camera lens be moved from its infinity setting to sharply focus an object 3.00 m away?

APPROACH For an object at infinity, the image is at the focal point, by definition as discussed in Section $23-7$. For an object distance of 3.00 m , we use the thin lens equation, Eq. 23–8, to find the image distance (distance of lens to film or sensor).

SOLUTION When focused at infinity, the lens is 50.0 mm from the film. When focused at $d_0 = 3.00$ m, the image distance is given by the lens equation,

We solve for d_i and find $d_i = 50.8$ mm, so the lens needs to move 0.8 mm away from the film or digital sensor.

EXERCISE A If the lens of Example $25-1$ is 50.4 mm from the film or sensor, what is the object distance for sharp focus?

CONCEPTUAL EXAMPLE 25-2 Shutter speed. To improve the depth of field, you "stop down" your camera lens by two f-stops from $f/4$ to $f/8$. What should you do to the shutter speed to maintain the same exposure?

RESPONSE The amount of light admitted by the lens is proportional to the area of the lens opening. Reducing the lens opening by two f-stops reduces the diameter by a factor of 2, and the area by a factor of 4. To maintain the same exposure, the shutter must be open four times as long. If the shutter speed had been $\frac{1}{500}$ s, you would have to increase it to $\frac{1}{125}$ s.

Picture Sharpness

The sharpness of a picture depends not only on accurate focusing, but also on the graininess of the film, or the number of pixels for a digital camera. Fine-grained films are "slower," meaning they require longer exposures for a given light level.

The quality of the lens strongly affects the image quality, and we discuss lens resolution and diffraction effects in Sections 25–6 and 25–7. The sharpness, or *resolution*, of a lens is often given as so many lines per millimeter, measured by photographing a standard set of parallel lines on fine-grain film. The minimum spacing of distinguishable lines gives the resolution; 50 lines/mm is reasonable, 100 lines/mm is very good.

EXAMPLE 25-3 Pixels and resolution. A high-quality 6-MP (6-megapixel) Pixels and resolution digital camera offers a maximum resolution of 2000×3000 pixels on a $16\text{-mm} \times 24\text{-mm }$ CCD sensor. How sharp should the lens be to make use of this resolution?

> **APPROACH** We find the number of pixels per millimeter and require the lens to be at least that good.

> **SOLUTION** We can either take the image height (2000 pixels in 16 mm) or the width (3000 pixels in 24 mm):

> > $\frac{3000 \text{ pixels}}{24 \text{ mm}} = 125 \text{ pixels/mm}.$

We would want the lens to be able to resolve at least 125 lines/mm as well. If it can't, we could use fewer pixels and less memory.

NOTE Increasing lens resolution is a tougher problem today than is squeezing more pixels on a CCD.

When is a photo sharp?

EXAMPLE 25-4 Blown-up photograph. An enlarged photograph looks sharp at normal viewing distances if the dots or lines are resolved to about 10 dots/mm. Would an 8×10 -inch enlargement of a photo taken by the camera in Example 25–3 seem sharp? To what maximum size could you enlarge this 2000×3000 -pixel image?

APPROACH We assume the image is 2000 \times 3000 pixels on a 16 \times 24-mm CCD as in Example $25-3$, or 125 pixels/mm. We make an enlarged photo 8×10 inches = 20 cm \times 25 cm.

SOLUTION The short side of the CCD is $16 \text{ mm} = 1.6 \text{ cm}$ long, and that side of the photograph is 8 inches or 20 cm. Thus the enlargement is by a factor of $20 \text{ cm}/1.6 \text{ cm} = 12.5 \times$ (or 25 cm/2.4 cm $\approx 10 \times$). To fill the 8 \times 10-inch paper, we assume the enlargement is $12.5\times$. The pixels are thus enlarged $12.5\times$; the pixel count of $125/\text{mm}$ on the CCD becomes $10/\text{mm}$ on the print, so an 8×10 -inch print is just about the maximum possible size for a sharp photograph. If you feel 7 dots/mm is good enough, you can enlarge to maybe 11×14 inches.

Telephotos and Wide-angles

Camera lenses are categorized into normal, telephoto, and wide angle, according to focal length and film size. A normal lens covers the film with a field of view that corresponds approximately to that of normal vision. A normal lens for 35-mm film has a focal length in the vicinity of 50 mm^+ . Telephoto lenses act like telescopes to magnify images. They have longer focal lengths than a normal lens: as we saw in Chapter 23 (Eq. $23-9$), the height of the image for a given object distance is proportional to the image distance, and the image distance will be greater for a lens with longer focal length. For distant objects, the image height is very nearly proportional to the focal length. Thus a 200-mm telephoto lens for use with a 35-mm camera gives a $4\times$ magnification over the normal 50-mm lens. A wide-angle lens has a shorter focal length than normal: a wider field of view is included, and objects appear smaller. A zoom lens is one whose focal length can be changed so that you seem to zoom up to, or away from, the subject as you change the focal length.

Digital cameras may have an "optical zoom" meaning the lens can change focal length and maintain resolution. But an "electronic" or "digital zoom" just enlarges the dots (pixels) with loss of sharpness.

Different types of viewing systems are common in cameras today. In many cameras, you view through a small window just above the lens as in Fig. 25–1. In a single-lens reflex camera (SLR), you actually view through the lens with the use of prisms and mirrors (Fig. 25–7). A mirror hangs at a 45° angle behind the lens and flips up out of the way just before the shutter opens. SLRs have the great advantage that you can see almost exactly what you will get on film. This is also true of the LCD display on a digital camera if it is carefully constructed.

-2 The Human Eye; Corrective Lenses

The human eye resembles a camera in its basic structure (Fig. $25-8$), but is far more sophisticated. The interior of the eye is filled with a transparent gel-like substance called the *vitreous humor* with index of refraction $n = 1.337$. Light enters this enclosed volume through the cornea and lens. Between the cornea and lens is a watery fluid, the aqueous humor (aqua is "water" in Latin) with $n = 1.336$. A diaphragm, called the **iris** (the colored part of your eye) adjusts automatically to control the amount of light entering the eye, similar to a camera. The hole in the iris through which light passes (the pupil) is black because no light is reflected from it (it's a hole), and very little light is reflected back out from the interior of the eye. The **retina**, which plays the role of the film or sensor in a camera, is on the curved rear surface of the eye. The retina consists of a complex array of nerves and receptors known as rods and cones which act to change light energy into electrical signals that travel along the nerves. The reconstruction of the image from all these tiny receptors is done mainly in the brain, although some analysis may also be done in the complex interconnected nerve network at the retina itself. At the center of the retina is a small area called the **fovea**, about 0.25 mm in diameter, where the cones are very closely packed and the sharpest image and best color discrimination are found.

Unlike a camera, the eye contains no shutter. The equivalent operation is carried out by the nervous system, which analyzes the signals to form images at the rate of about 30 per second. This can be compared to motion picture or television cameras, which operate by taking a series of still pictures at a rate of 24 (movies) or 30 (U.S. television) per second. Their rapid projection on the screen gives the appearance of motion.

The lens of the eye ($n = 1.386$ to 1.406) does little of the bending of the light rays. Most of the refraction is done at the front surface of the **cornea** ($n = 1.376$) at its interface with air ($n = 1.0$). The lens acts as a fine adjustment for focusing at different distances. This is accomplished by the ciliary muscles (Fig. $25-8$), which change the curvature of the lens so that its focal length is changed.

Telephoto and wide-angle lenses

Mirror

FIGURE 25-7 Single-lens reflex (SLR) camera, showing how the image is viewed through the lens with the help of a movable mirror and prism.

PHYSICS APPLIED The eve

Anatomy of the eye

 † A "35-mm camera" uses film that is 35 mm wide; that 35 mm is not to be confused with a focal length.

PHYSICS APPLIED Corrective lenses

Nearsightedness

To focus on a distant object, the ciliary muscles of the eye are relaxed and the lens is thin, as shown in Fig. 25–9a, and parallel rays focus at the focal point (on the retina). To focus on a nearby object, the muscles contract, causing the center of the lens to thicken. Fig. 25–9b, thus shortening the focal length so that images of nearby objects can be focused on the retina, behind the new focal point. This focusing adjustment is called **accommodation**.

The closest distance at which the eve can focus clearly is called the **near point** of the eye. For young adults it is typically 25 cm, although younger children can often focus on objects as close as 10 cm. As people grow older, the ability to accommodate is reduced and the near point increases. A given person's far point is the farthest distance at which an object can be seen clearly. For some purposes it is useful to speak of a normal eye (a sort of average over the population), defined as an eye having a near point of 25 cm and a far point of infinity. To check your own near point, place this book close to your eye and slowly move it away until the type is sharp.

The "normal" eye is sort of an ideal. Many people have eyes that do not accommodate within the "normal" range of 25 cm to infinity, or have some other defect. Two common defects are nearsightedness and farsightedness. Both can be corrected to a large extent with lenses—either eyeglasses or contact lenses.

In nearsightedness, or *myopia*, the eye can focus only on nearby objects. The far point is not infinity but some shorter distance, so distant objects are not seen clearly. It is usually caused by an eyeball that is too long, although sometimes it is the curvature of the cornea that is too great. In either case, images of distant objects are focused in front of the retina. A diverging lens, because it causes parallel rays to diverge, allows the rays to be focused at the retina (Fig. $25-10a$) and thus corrects this defect.

FIGURE 25-10 Correcting eye defects with lenses: (a) a nearsighted eye, which cannot focus clearly on distant objects, can be corrected by use of a diverging lens; (b) a farsighted eye, which cannot focus clearly on nearby objects, can be corrected by use of a converging lens.

Farsightedness

In farsightedness, or *hyperopia*, the eye cannot focus on nearby objects. Although distant objects are usually seen clearly, the near point is somewhat greater than the "normal" 25 cm, which makes reading difficult. This defect is caused by an eyeball that is too short or (less often) by a cornea that is not sufficiently curved. It is corrected by a converging lens, Fig. 25-10b. Similar to hyperopia is *presbyopia*, which refers to the lessening ability of the eye to accommodate as one ages, and the near point moves out. Converging lenses also compensate for this.

Astigmatism is usually caused by an out-of-round cornea or lens so that point objects are focused as short lines, which blurs the image. It is as if the cornea were spherical with a cylindrical section superimposed. As shown in Fig. 25–11, a cylindrical lens focuses a point into a line parallel to its axis. An astigmatic eye may focus rays in one plane, such as the vertical plane, at a shorter distance than it does for rays in a horizontal plane. Astigmatism is corrected with the use of a compensating cylindrical lens. Lenses for eyes that are nearsighted or farsighted as well as astigmatic are ground with superimposed spherical and cylindrical surfaces, so that the radius of curvature of the correcting lens is different in different planes.

Astigmatism

FIGURE 25-11 A cylindrical lens forms a line image of a point object because it is converging in one. plane only.

EXAMPLE 25-5 Farsighted eye. Sue is farsighted with a near point of 100 cm. Reading glasses must have what lens power so that she can read a newspaper at a distance of 25 cm? Assume the lens is very close to the eye.

APPROACH When the object is placed 25 cm from the lens, we want the image to be 100 cm away on the *same* side of the lens (so the eye can focus it), and so the image is virtual, Fig. 25–12, and $d_i = -100$ cm will be negative. We use the thin lens equation (Eq. $23-8$) to determine the needed focal length. Optometrists' prescriptions specify the power $(P = 1/f, Eq. 23-7)$ given in diopters $(1 D = 1 m^{-1})$.

SOLUTION Given that $d_0 = 25$ cm and $d_1 = -100$ cm, the thin lens equation gives

$$
\frac{1}{f} = \frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{25 \text{ cm}} + \frac{1}{-100 \text{ cm}} = \frac{4 - 1}{100 \text{ cm}} = \frac{1}{33 \text{ cm}}.
$$

So $f = 33$ cm = 0.33 m. The power P of the lens is $P = 1/f = +3.0$ D. The plus sign indicates that it is a converging lens.

NOTE We chose the image position to be where the eye can actually focus. The lens needs to put the image there, given the desired placement of the object (newspaper).

FIGURE 25-12 Lens of reading glasses (Example 25-5).

EXAMPLE 25-6 Nearsighted eye. A nearsighted eye has near and far points of 12 cm and 17 cm, respectively. (a) What lens power is needed for this person to see distant objects clearly, and (b) what then will be the near point? Assume that the lens is 2.0 cm from the eye (typical for eyeglasses).

APPROACH For a distant object $(d_0 = \infty)$, the lens must put the image at the far point of the eye as shown in Fig. 25–13a, 17 cm in front of the eye. We can use the thin lens equation to find the focal length of the lens, and from this its lens power. The new near point (as shown in Fig. $25-13b$) can be calculated for the lens by again using the thin lens equation.

SOLUTION (a) For an object at infinity $(d_0 = \infty)$, the image must be in front of the lens 17 cm from the eye or $(17 \text{ cm} - 2 \text{ cm}) = 15 \text{ cm}$ from the lens; hence $d_i = -15$ cm. We use the thin lens equation to solve for the focal length of the needed lens:

$$
\frac{1}{f} = \frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{\infty} + \frac{1}{-15 \text{ cm}} = -\frac{1}{15 \text{ cm}}
$$

So $f = -15$ cm = -0.15 m or $P = 1/f = -6.7$ D. The minus sign indicates that it must be a diverging lens for the myopic eye.

(b) The near point when glasses are worn is where an object is placed (d_0) so that the lens forms an image at the "near point of the naked eye," namely 12 cm from the eye. That image point is $(12 \text{ cm} - 2 \text{ cm}) = 10 \text{ cm}$ in front of the lens, so $d_i = -0.10$ m and the thin lens equation gives

$$
\frac{1}{d_o} = \frac{1}{f} - \frac{1}{d_i} = -\frac{1}{0.15 \text{ m}} + \frac{1}{0.10 \text{ m}} = \frac{-2 + 3}{0.30 \text{ m}} = \frac{1}{0.30 \text{ m}}
$$

So $d_0 = 30$ cm, which means the near point when the person is wearing glasses is 30 cm in front of the lens, or 32 cm from the eye.

Contact lenses

contact lens and an eveglass lens will require slightly different powers, or focal lengths, for the same eye because of their different placements relative to the eye. We also see that glasses in this case give a better near point than contacts.

EXERCISE B What power contact lens is needed for an eye to see distant objects if its far point is 25 cm?

Underwater Vision

When your eyes are under water, distant underwater objects look blurry because at the water-cornea interface, the difference in indices of refraction is very small: $n = 1.33$ for water, 1.376 for the cornea. Hence light rays are bent very little and are focused far behind the retina, Fig. 25–14a. If you wear goggles or a face mask, you restore an air-cornea interface $(n = 1.0$ and 1.376, respectively) and the rays can be focused, Fig. 25–14b.

 $\left(\uparrow\right)$ PHYSICS APPLIED

Underwater vision

FIGURE 25-15 When the same object is viewed at a shorter distance, the image on the retina is greater, so the object appears larger and more detail can be seen. The angle θ that the object subtends in (a) is greater than in (b) . *Note*: This is not a normal ray diagram because we are showing only one ray from each point.

25-3 Magnifying Glass

Much of the remainder of this Chapter will deal with optical devices that are used to produce magnified images of objects. We first discuss the simple magnifier, or magnifying glass, which is simply a converging lens (see Chapter-opening photo).

How large an object appears, and how much detail we can see on it, depends on the size of the image it makes on the retina. This, in turn, depends on the angle subtended by the object at the eye. For example, a penny held 30 cm from the eye looks twice as tall as one held 60 cm away because the angle it subtends is twice as great (Fig. $25-15$). When we want to examine detail on an object, we bring it up close to our eyes so that it subtends a greater angle. However, our eyes can accommodate only up to a point (the near point), and we will assume a standard distance of $N = 25$ cm as the near point in what follows.

A magnifying glass allows us to place the object closer to our eye so that it subtends a greater angle. As shown in Fig. 25-16a, the object is placed at the focal point or just within it. Then the converging lens produces a virtual image, which must be at least 25 cm from the eye if the eye is to focus on it. If the eye is relaxed, the image will be at infinity, and in this case the object is exactly at the focal point. (You make this slight adjustment yourself when you "focus" on the object by moving the magnifying glass.)

A comparison of part (a) of Fig. 25–16 with part (b), in which the same object is viewed at the near point with the unaided eye, reveals that the angle the object subtends at the eye is much larger when the magnifier is used. The angular magnification or magnifying power, M , of the lens is defined as the ratio of the angle subtended by an object when using the lens, to the angle subtended using the unaided eye, with the object at the near point N of the eye $(N = 25$ cm for a normal eve):

$$
M = \frac{\theta'}{\theta},\tag{25-1}
$$

where θ and θ' are shown in Fig. 25–16. We can write M in terms of the focal length by noting that $\theta = h/N$ (Fig. 25–16b) and $\theta' = h/d_0$ (Fig. 25–16a), where h is the height of the object and we assume the angles are small so θ and θ' equal their sines and tangents. If the eye is relaxed (for least eye strain), the image will be at infinity and the object will be precisely at the focal point; see Fig. 25–17. Then $d_0 = f$ and $\theta' = h/f$. Thus

$$
M = \frac{\theta'}{\theta} = \frac{h/f}{h/N} = \frac{N}{f}.\qquad \left[\begin{array}{c} \text{eye focused at } \infty; \\ N = 25 \text{ cm for normal eye} \end{array}\right] \text{ (25-2)}
$$

We see that the shorter the focal length of the lens, the greater the magnification.[†]

The magnification of a given lens can be increased a bit by moving the lens and adjusting your eye so it focuses on the image at the eye's near point. In this case, $d_i = -N$ (see Fig. 25–16a) if your eye is very near the magnifier. Then the object distance d_0 is given by

$$
\frac{1}{d_{o}} = \frac{1}{f} - \frac{1}{d_{i}} = \frac{1}{f} + \frac{1}{N}.
$$

 Δt

 α r

We see from this equation that $d_0 = fN/(f + N) < f$, as shown in Fig. 25–16a, since $N/(f + N)$ must be less than 1. With $\theta' = h/d_0$ the magnification is

$$
M = \frac{\theta'}{\theta} = \frac{h/d_0}{h/N} = \frac{N}{d_0} = N\left(\frac{1}{f} + \frac{1}{N}\right)
$$

$$
M = \frac{N}{f} + 1.
$$
 [eye focused at near point, N;

$$
N = 25 \text{ cm for normal eye}
$$
 (25-2b)

We see that the magnification is slightly greater when the eye is focused at its near point, rather than relaxed.

EXAMPLE 25-7 ESTIMATE A jeweler's "loupe." An 8-cm-focallength converging lens is used as a "jeweler's loupe," which is a magnifying glass. Estimate (a) the magnification when the eye is relaxed, and (b) the magnification if the eye is focused at its near point $N = 25$ cm.

APPROACH The magnification when the eye is relaxed is given by Eq. $25-2a$. When the eye is focused at its near point, we use Eq. $25-2b$ and we assume the lens is near the eye.

SOLUTION (a) With the relaxed eye focused at infinity,

$$
M = \frac{N}{f} = \frac{25 \text{ cm}}{8 \text{ cm}} \approx 3 \times.
$$

(b) The magnification when the eye is focused at its near point ($N = 25$ cm), and the lens is near the eye, is

$$
M = 1 + \frac{N}{f} = 1 + \frac{25}{8} \approx 4 \times
$$

FIGURE 25-17 With the eye relaxed, the object is placed at the focal point, and the image is at infinity. Compare to Fig. 25-16a where the image is at the eye's near point.

^{\dagger}Simple single-lens magnifiers are limited to about 2 or $3\times$ because of distortion due to spherical aberration (Section 25-6).

FIGURE 25-18 (a) Objective lens (mounted now in an ivory frame) from the telescope with which Galileo made his world-shaking discoveries, including the moons of Jupiter. (b) Later telescopes made by Galileo.

Telescope magnification

25-4 Telescopes

A telescope is used to magnify objects that are very far away. In most cases, the object can be considered to be at infinity.

Galileo, although he did not invent it, \dagger developed the telescope into a usable and important instrument. He was the first to examine the heavens with the telescope (Fig. $25-18$), and he made world-shaking discoveries: the moons of Jupiter, the phases of Venus, sunspots, the structure of the Moon's surface, that the Milky Way is made up of a huge number of individual stars, and others.

Several types of astronomical telescope exist. The common refracting type, sometimes called Keplerian, contains two converging lenses located at opposite ends of a long tube, as illustrated in Fig. 25–19. The lens closest to the object is called the **objective lens** (focal length f_0) and forms a real image I_1 of the distant object in the plane of its focal point F_0 (or near it if the object is not at infinity). Although this image, I_1 , is smaller than the original object, it subtends a greater angle and is very close to the second lens, called the **eyepiece** (focal length f_e), which acts as a magnifier. That is, the eyepiece magnifies the image produced by the objective lens to produce a second, greatly magnified image, I_2 , which is virtual and inverted. If the viewing eye is relaxed, the eyepiece is adjusted so the image I_2 is at infinity. Then the real image I_1 is at the focal point F'_e of the eyepiece, and the distance between the lenses is $f_0 + f_e$ for an object at infinity.

To find the total magnification of this telescope, we note that the angle an object subtends as viewed by the unaided eye is just the angle θ subtended at the telescope objective. From Fig. 25–19 we can see that $\theta \approx h/f_0$, where h is the height of the image I_1 and we assume θ is small so that $\tan \theta \approx \theta$. Note, too, that the thickest of the three rays drawn in Fig. 25-19 is parallel to the axis before it strikes the eyepiece and therefore is refracted through the eyepiece focal point F_c on the far side. Thus, $\theta' \approx h/f_c$ and the total magnifying power (angular magnification) of this telescope is

$$
M = \frac{\theta'}{\theta} = \frac{(h/f_e)}{(h/f_o)} = -\frac{f_o}{f_e},\tag{25-3}
$$

where we have inserted a minus sign to indicate that the image is inverted. To achieve a large magnification, the objective lens should have a long focal length and the eyepiece a short focal length.

[†]Galileo built his first telescope in 1609 after having heard of such an instrument existing in Holland. The first telescopes magnified only three to four times, but Galileo soon made a 30-power instrument. The first Dutch telescope seems to date from about 1604, but there is a reference suggesting it may have been copied from an Italian telescope built as early as 1590. Kepler (see Chapter 5) gave a ray description (in 1611) of the Keplerian telescope, which is named for him because he first described it, although he did not build it.

EXAMPLE 25-8 Telescope magnification. The largest optical refracting telescope in the world is located at the Yerkes Observatory in Wisconsin, Fig. 25-20. It is referred to as a "40-inch" telescope, meaning that the diameter of the objective is 40 in., or 102 cm. The objective lens has a focal length of 19 m, and the eyepiece has a focal length of 10 cm. (a) Calculate the total magnifying power of this telescope. (b) Estimate the length of the telescope.

APPROACH Equation 25–3 gives the magnification. The length of the telescope is the distance between the two lenses.

SOLUTION (a) From Eq. 25-3 we find

$$
M = -\frac{f_o}{f_e} = -\frac{19 \text{ m}}{0.10 \text{ m}} = -190 \times.
$$

(b) For a relaxed eye, the image I_1 is at the focal point of both the eyepiece and the objective lenses. The distance between the two lenses is thus $f_0 + f_e \approx 19$ m, which is essentially the length of the telescope.

EXERCISE C A 40× telescope has a 1.2-cm focal length eyepiece. What is the focal length of the objective lens?

For an astronomical telescope to produce bright images of distant stars, the objective lens must be large to allow in as much light as possible. Indeed, the diameter of the objective lens (and hence its "light-gathering power") is an important parameter for an astronomical telescope, which is why the largest ones are specified by giving the objective diameter (such as the 10-meter Keck telescope in Hawaii). The construction and grinding of large lenses is very difficult. Therefore, the largest telescopes are reflecting telescopes which use a curved mirror as the objective, Fig. $25-21$. A mirror has only one surface to be ground and can be supported along its entire surface ϕ (a large lens, supported at its edges, would sag under its own weight). Often, the eyepiece lens or mirror (see Fig. $25-21$) is removed so that the real image formed by the objective mirror can be recorded directly on film or on a CCD digital sensor (Section 25-1).

*Another advantage of mirrors is that they exhibit no chromatic aberration because the light doesn't pass through them; and they can be ground in a parabolic shape to correct for spherical aberration (Section 25-6). The reflecting telescope was first proposed by Newton.

FIGURE 25-21 A concave mirror can be used as the objective of an astronomical telescope. Either (a) a lens or (b) a mirror can be used as the eyepiece. Arrangement (a) is called the Newtonian focus, and (b) the Cassegrainian focus. Other arrangements are also possible. (c) The 200-inch (mirror diameter) Hale telescope on Palomar Mountain in California. (d) The 10-meter Keck telescope on Mauna Kea, Hawaii. The Keck combines thirty-six 1.8-meter six-sided mirrors into the equivalent of a very large single reflector, 10 m in diameter.

FIGURE 25-20 This large refracting telescope was built in 1897 and is housed at Yerkes Observatory in Wisconsin. The objective lens is 102 cm (40 inches) in diameter, and the telescope tube is about 19 m long. Example 25-8.

Reflecting telescopes

 \overline{A}) PHYSICS APPLIED

Microscopes

A terrestrial telescope, for viewing objects on Earth, must provide an upright image—seeing normal objects upside down would be difficult (much less important for viewing stars). Two designs are shown in Fig. 25–22. The Galilean type, which Galileo used for his great astronomical discoveries, has a diverging lens as evepiece which intercepts the converging rays from the objective lens before they reach a focus, and acts to form a virtual upright image, Fig. 25–22a. This design is often used in opera glasses. The tube is reasonably short, but the field of view is small. The second type, shown in Fig. 25-22b, is often called a spyglass and makes use of a third convex lens that acts to make the image upright as shown. A spyglass must be quite long. The most practical design today is the prism binocular which was shown in Fig. 23-26. The objective and eyepiece are converging lenses. The prisms reflect the rays by total internal reflection and shorten the physical size of the device, and they also act to produce an upright image. One prism reinverts the image in the vertical plane, the other in the horizontal plane.

-5 Compound Microscope

The compound microscope, like the telescope, has both objective and eyepiece (or ocular) lenses, Fig. 25-23. The design is different from that for a telescope because a microscope is used to view objects that are very close, so the object distance is very small. The object is placed just beyond the objective's focal point as shown in Fig. 25–23a. The image I_1 formed by the objective lens is real, quite far from the lens, and much enlarged. This image is magnified by the eyepiece into a very large virtual image, I_2 , which is seen by the eye and is inverted.

then up through the slide holding the object).

The overall magnification of a microscope is the product of the magnifications produced by the two lenses. The image I_1 formed by the objective lens is a factor m_0 greater than the object itself. From Fig. 25–23a and Eq. 23–9 for the magnification of a simple lens, we have

$$
m_o = \frac{h_i}{h_o} = \frac{d_i}{d_o} = \frac{l - f_e}{d_o},
$$
\n(25-4)

where d_0 and d_i are the object and image distances for the objective lens, l is the distance between the lenses (equal to the length of the barrel), and we ignored the minus sign in Eq. 23–9 which only tells us that the image is inverted. We set $d_i = l - f_c$, which is true only if the eye is relaxed, so that the image I₁ is at the eyepiece focal point F_e . The eyepiece acts like a simple magnifier. If we assume that the eye is relaxed, the eyepiece angular magnification M_e is (from Eq. $25-2a$)

$$
M_{\rm e} = \frac{N}{f_{\rm e}},\tag{25-5}
$$

where the near point $N = 25$ cm for the normal eye. Since the eyepiece enlarges the image formed by the objective, the overall angular magnification M is the product of the lateral magnification of the objective lens, m_0 , times the angular magnification, M_e , of the eyepiece lens (Eqs. 25–4 and 25–5):

$$
M = M_{\rm e} m_{\rm o} = \left(\frac{N}{f_{\rm e}}\right) \left(\frac{l - f_{\rm e}}{d_{\rm o}}\right)
$$
\n
$$
\approx \frac{N l}{f_{\rm e} f_{\rm o}}.
$$
\n(25-6a)

\n[$f_{\rm o}$ and $f_{\rm e} \ll l$] (25-6b)

of

Magnification

microscope

The approximation, Eq. 25–6b, is accurate when f_c and f_o are small compared to *l*, so $l - f_e \approx l$ and $d_o \approx f_o$ (Fig. 25–23a). This is a good approximation for large magnifications, which are obtained when f_0 and f_e are very small (they are in the denominator of Eq. 25-6b). To make lenses of very short focal length, which can be done best for the objective, compound lenses involving several elements must be used to avoid serious aberrations, as discussed in the next Section.

EXAMPLE 25-9 Microscope. A compound microscope consists of a $10\times$ eyepiece and a $50\times$ objective 17.0 cm apart. Determine (a) the overall magnification, (b) the focal length of each lens, and (c) the position of the object when the final image is in focus with the eye relaxed. Assume a normal eye, so $N = 25$ cm.

APPROACH The overall magnification is the product of the eyepiece magnification and the objective magnification. The focal length of the eyepiece is found from Eq. 25-2a or 25-5 for the magnification of a simple magnifier. For the objective lens, it is easier to next find d_0 (part c) using Eq. 25–4 before we find f_{0} .

SOLUTION (a) The overall magnification is $(10\times)(50\times) = 500\times$. (b) The eyepiece focal length is (Eq. 25–5) $f_e = N/M_e = 25$ cm/10 = 2.5 cm. Next we solve Eq. 25–4 for d_0 , and find

$$
d_{\rm o} = \frac{l - f_{\rm e}}{m_{\rm o}} = \frac{(17.0 \, \text{cm} - 2.5 \, \text{cm})}{50} = 0.29 \, \text{cm}.
$$

Then, from the thin lens equation for the objective with $d_i = l - f_e = 14.5$ cm (see Fig. 25-23a),

$$
\frac{1}{f_o} = \frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{0.29 \text{ cm}} + \frac{1}{14.5 \text{ cm}} = 3.52 \text{ cm}^{-1};
$$

so $f_0 = 1/(3.52 \text{ cm}^{-1}) = 0.28 \text{ cm}.$

(c) We just calculated $d_0 = 0.29$ cm, which is very close to f_0 .

25-6 Aberrations of Lenses and Mirrors

In Chapter 23, we developed a theory of image formation by a thin lens. We found, for example, that all rays from each point on an object are brought to a single point as the image point. This, and other results, were based on approximations such as that all rays make small angles with one another and we can use $\sin \theta \approx \theta$. Because of these approximations, we expect deviations from the simple theory, and these are referred to as lens aberrations. There are several types of aberration; we will briefly discuss each of them separately, but all may be present at one time.

Consider an object at any point (even at infinity) on the axis of a lens. Rays from this point that pass through the outer regions of the lens are brought to a focus at a different point from those that pass through the center of the lens. This is called **spherical aberration**, and is shown exaggerated in Fig. $25-24$.

Spherical aberration

FIGURE 25-24 Spherical aberration (exaggerated). Circle of least confusion is at C.

Consequently, the image seen on a piece of film (for example) will not be a point but a tiny circular patch of light. If the film is placed at the point C, as indicated, the circle will have its smallest diameter, which is referred to as the circle of least confusion. Spherical aberration is present whenever spherical surfaces are used. It can be corrected by using nonspherical lens surfaces, but to grind such lenses is difficult and expensive. It can be minimized with spherical surfaces by choosing the curvatures so that equal amounts of bending occur at each lens surface; a lens can be designed like this for only one particular object distance. Spherical aberration is usually corrected (by which we mean reduced greatly) by the use of several lenses in combination, and by using only the central part of lenses.

For object points off the lens axis, additional aberrations occur. Rays passing through the different parts of the lens cause spreading of the image that is noncircular. There are two effects: coma (because the image of a point is comet-shaped rather than a circle) and **off-axis astigmatism**.[†] Furthermore, the image points for objects off the axis but at the same distance from the lens do not fall on a flat plane but on a curved surface—that is, the focal plane is not flat. (We expect this because the points on a flat plane, such as the film in a camera, are not equidistant from the lens.) This aberration is known as curvature of field and is a problem in cameras and other devices where the film is placed in a flat plane. In the eye, however, the retina is curved, which compensates for this effect.

Another aberration, known as **distortion**, is a result of variation of magnification at different distances from the lens axis. Thus a straight-line object some distance from the axis may form a curved image. A square grid of lines may be distorted to produce "barrel distortion," or "pincushion distortion," Fig. 25–25. The latter is common in extreme wide-angle lenses.

All the above aberrations occur for monochromatic light and hence are referred to as monochromatic aberrations. Normal light is not monochromatic, and there will also be **chromatic aberration**. This aberration arises because of dispersion—the variation of index of refraction of transparent materials with wavelength (Section 24-4). For example, blue light is bent more than red light

Although the effect is the same as for astigmatism in the eye (Section 25–2), the cause is different. Off-axis astigmatism is no problem in the eye because objects are clearly seen only at the fovea, on the lens axis.

Off-axis aberrations

FIGURE 25-25 Distortion: lenses may image a square grid of perpendicular lines to produce (a) barrel distortion or (b) pincushion distortion. These distortions can be seen in the photograph of Fig. 23-29d.

by glass. So if white light is incident on a lens, the different colors are focused at different points, Fig. 25–26, and there will be colored fringes in the image. Chromatic aberration can be eliminated for any two colors (and reduced greatly for all others) by the use of two lenses made of different materials with different indices of refraction and dispersion. Normally one lens is converging and the other diverging, and they are often cemented together (Fig. 25–27). Such a lens combination is called an achromatic doublet (or "color-corrected" lens).

It is not possible to fully correct all aberrations. Combining two or more lenses together can reduce them. High-quality lenses used in cameras, microscopes, and other devices are compound lenses consisting of many simple lenses (referred to as **elements**). A typical high-quality camera lens may contain six to eight (or more) elements. For simplicity we will usually indicate lenses in diagrams as if they were simple lenses.

The human eye is also subject to aberrations, but they are minimal. Spherical aberration, for example, is minimized because (1) the cornea is less curved at the edges than at the center, and (2) the lens is less dense at the edges than at the center. Both effects cause rays at the outer edges to be bent less strongly, and thus help to reduce spherical aberration. Chromatic aberration is partially compensated for because the lens absorbs the shorter wavelengths appreciably and the retina is less sensitive to the blue and violet wavelengths. This is just the region of the spectrum where dispersion—and thus chromatic aberration—is greatest (Fig. $24-14$).

Spherical mirrors (Section 23–3) also suffer aberrations including spherical aberration (see Fig. $23-11$). Mirrors can be ground in a parabolic shape to correct for spherical aberration, but they are much harder to make and therefore very expensive. Spherical mirrors do not, however, exhibit chromatic aberration because the light does not pass through them (no refraction, no dispersion).

25–7 Limits of Resolution; Circular Apertures

The ability of a lens to produce distinct images of two point objects very close together is called the resolution of the lens. The closer the two images can be and still be seen as distinct (rather than overlapping blobs), the higher the resolution. The resolution of a camera lens, for example, is often specified as so many lines per millimeter, as mentioned in Section 25-1.

Two principal factors limit the resolution of a lens. The first is lens aberrations. As we saw, because of spherical and other aberrations, a point object is not a point on the image but a tiny blob. Careful design of compound lenses can reduce aberrations significantly, but they cannot be eliminated entirely. The second factor that limits resolution is *diffraction*, which cannot be corrected for optically because it is a natural result of the wave nature of light. We discuss it now.

In Section 24–5 we saw that because light travels as a wave, light from a point source passing through a slit is spread out into a diffraction pattern (Figs. 24–19 and 24–21). A lens, because it has edges, acts like a slit. When a lens forms the image of a point object, the image is actually a tiny diffraction pattern. Thus an image would be blurred even if aberrations were absent.

FIGURE 25-26 Chromatic aberration. Different colors are focused at different points.

FIGURE 25-27 Achromatic doublet.

FIGURE 25-28 Photographs of images (greatly magnified) formed by a lens, showing the diffraction pattern of an image for: (a) a single point object; (b) two point objects whose images are barely resolved.

In the analysis that follows, we assume that the lens is free of aberrations, so we can concentrate on diffraction effects and how much they limit the resolution of a lens. In Fig. $24-21$ we saw that the diffraction pattern produced by light passing through a rectangular slit has a central maximum in which most of the light falls. This central peak falls to a minimum on either side of its center at an angle θ given by

$$
\sin \theta = \frac{\lambda}{D}
$$

(this is Eq. 24–3a), where D is the slit width and λ the wavelength of light used. θ is the angular half-width of the central maximum, and for small angles can be written

$$
\theta \approx \sin \theta = \frac{\lambda}{D}.
$$

There are also low-intensity fringes beyond. For a lens, or any circular hole, the image of a point object will consist of a circular central peak (called the diffraction spot or Airy disk) surrounded by faint circular fringes, as shown in Fig. 25–28a. The central maximum has an angular half width given by

Smaller angle means better resolution

where D is the diameter of the circular opening.

This formula differs from that for a slit $(Eq. 24-3)$ by the factor 1.22. This factor appears because the width of a circular hole is not uniform (like a rectangular slit) but varies from its diameter D to zero. A mathematical analysis shows that the "average" width is $D/1.22$. Hence we get the equation above rather than Eq. 24–3. The intensity of light in the diffraction pattern of light from a point source passing through a circular opening is shown in Fig. 25–29. The image for a non-point source is a superposition of such patterns. For most purposes we need consider only the central spot, since the concentric rings are so much dimmer.

If two point objects are very close, the diffraction patterns of their images will overlap as shown in Fig. 25–28b. As the objects are moved closer, a separation is reached where you can't tell if there are two overlapping images or a single image. The separation at which this happens may be judged differently by different observers. However, a generally accepted criterion is that proposed by Lord Rayleigh (1842–1919). This Rayleigh criterion states that two images are just resolvable when the center of the diffraction disk of one image is directly over the first minimum in the diffraction pattern of the other. This is shown in Fig. 25–30. Since the first minimum is at an angle $\theta = 1.22\lambda/D$ from the central maximum, Fig. 25-30 shows that two objects can be considered just *resolvable* if they are separated by at least the angle θ given by

Rayleigh criterion (resolution limit) $\theta = \frac{1.22 \lambda}{D}.$ [θ in radians] (25-7)

This is the limit on resolution set by the wave nature of light due to diffraction. A smaller angle means better resolution: you can make out closer objects. We see from Eq. 25–7 that using a shorter wavelength λ can increase resolution.

FIGURE 25-30 The Rayleigh criterion. Two images are just resolvable when the center of the diffraction peak of one is directly over the first minimum in the diffraction pattern of the other. The two point objects O and O' subtend an angle θ at the lens; only one ray (it passes through the center of the lens) is drawn for each object, to indicate the center of the diffraction pattern of its image.

EXAMPLE 25-10 Hubble Space Telescope. The Hubble Space Telescope (HST) is a reflecting telescope that was placed in orbit above the Earth's atmosphere, so its resolution would not be limited by turbulence in the atmosphere (Fig. 25–31). Its objective diameter is 2.4 m. For visible light, say λ = 550 nm, estimate the improvement in resolution the Hubble offers over Earth-bound telescopes, which are limited in resolution by movement of the Earth's atmosphere to about half an arc second. (Each degree is divided into 60 minutes each containing 60 seconds, so $1^{\circ} = 3600$ arc seconds.)

APPROACH Angular resolution for the Hubble is given (in radians) by Eq. 25–7. The resolution for Earth telescopes is given, and we first convert it to radians so we can compare.

SOLUTION Earth-bound telescopes are limited to an angular resolution of

$$
\theta = \frac{1}{2} \left(\frac{1}{3600} \right)^{\circ} \left(\frac{2\pi \text{ rad}}{360^{\circ}} \right) = 2.4 \times 10^{-6} \text{ rad.}
$$

The Hubble, on the other hand, is limited by diffraction (Eq. $25-7$) which for $\lambda = 550$ nm is

$$
\theta = \frac{1.22\lambda}{D} = \frac{1.22(550 \times 10^{-9} \text{ m})}{2.4 \text{ m}} = 2.8 \times 10^{-7} \text{ rad},
$$

thus giving almost ten times better resolution $(2.4 \times 10^{-6} \text{rad}/2.8 \times 10^{-7} \text{rad} \approx 9 \times)$. **NOTE** The Hubble can also observe radiation in the near ultraviolet (wavelengths as small as 115 nm) and infrared (wavelengths as long as 1 mm), which are ranges of the spectrum blocked by the atmosphere. The sensor is a CCD, as in a camera (see Section $25-1$), with a pixel count of 16 MP.

EXAMPLE 25-11 ESTIMATE Eye resolution. You are in an airplane at an altitude of 10,000 m. If you look down at the ground, estimate the minimum separation s between objects that you could distinguish. Consider only diffraction, and assume your pupil is about 3.0 mm in diameter and $\lambda = 550$ nm.

APPROACH We use the Rayleigh criterion, Eq. 25-7, to estimate θ . The separation s of objects equals their distance away, $L = 10^4$ m, times θ (in radians) as θ is small, so $s = L\theta$.

SOLUTION In Eq. 25–7, we set $D = 3.0$ mm for the opening of the eye:

$$
s = L\theta = L\frac{1.22\lambda}{D}
$$

=
$$
\frac{(10^4 \text{ m})(1.22)(550 \times 10^{-9} \text{ m})}{3.0 \times 10^{-3} \text{ m}} = 2.2 \text{ m}
$$

FIGURE 25-31 Hubble Space Telescope, with Earth in the background. The flat orange panels are solar cells that collect energy from the Sun.

EXERCISE D Someone claims a spy satellite camera can see 3-cm-high newspaper headlines from an altitude of 100 km. If diffraction were the only limitation $(\lambda = 550 \text{ nm})$, use Eq. 25–7 to determine what diameter lens the camera would have.

25-8 Resolution of Telescopes and Microscopes; the λ Limit

You might think that a microscope or telescope could be designed to produce any desired magnification, depending on the choice of focal lengths and quality of the lenses. But this is not possible, because of diffraction. An increase in magnification above a certain point merely results in magnification of the diffraction patterns. This can be highly misleading since we might think we are seeing details of an object when we are really seeing details of the diffraction pattern. To examine this problem, we apply the Rayleigh criterion: two objects (or two nearby points on one object) are just resolvable if they are separated by an angle θ (Fig. 25–30) given by Eq. 25–7:

$$
\theta = \frac{1.22\lambda}{D}.
$$

This formula is valid for either a microscope or a telescope, where D is the diameter of the objective lens. For a telescope, the resolution is specified by stating θ as given by this equation.[†]

For a microscope, it is more convenient to specify the actual distance, s , between two points that are just barely resolvable: see Fig. 25–30. Since objects are normally placed near the focal point of the microscope objective, the angle subtended by two objects is $\theta = s/f$, or $s = f\theta$. If we combine this with Eq. 25–7, we obtain for the **resolving power** (\mathbf{RP}) of a microscope

Resolving power

$$
RP = s = f\theta = \frac{1.22\lambda f}{D},
$$
\n(25-8)

where f is the objective lens' focal length (not frequency). This distance s is called the resolving power of the lens because it is the minimum separation of two object points that can just be resolved, assuming the highest quality lens since this limit is imposed by the wave nature of light. A smaller RP means better resolution, better detail.

EXAMPLE 25-12 Telescope resolution (radio wave vs. visible light). What is the theoretical minimum angular separation of two stars that can just be resolved by (a) the 200-inch telescope on Palomar Mountain (Fig. 25–21c); and (b) the Arecibo radiotelescope (Fig. 25–32), whose diameter is 300 m and whose radius of curvature is also 300 m. Assume $\lambda = 550$ nm for the visiblelight telescope in part (a), and $\lambda = 4$ cm (the shortest wavelength at which the radiotelescope has been operated) in part (b) .

APPROACH We apply the Rayleigh criterion (Eq. 25-7) for each telescope. **SOLUTION** (a) Since $D = 200$ in. = 5.1 m, we have from Eq. 25-7 that

$$
\theta = \frac{1.22\lambda}{D} = \frac{(1.22)(5.50 \times 10^{-7} \text{ m})}{(5.1 \text{ m})} = 1.3 \times 10^{-7} \text{ rad}
$$

or 0.75×10^{-5} deg. (Note that this is equivalent to resolving two points less than 1 cm apart from a distance of 100 km!)

(b) For radio waves with $\lambda = 0.04$ m, the resolution is

$$
\theta = \frac{(1.22)(0.04 \text{ m})}{(300 \text{ m})} = 1.6 \times 10^{-4} \text{ rad.}
$$

The resolution is less because the wavelength is so much larger, but the larger objective is a plus.

Earth-bound telescopes with large-diameter objectives are usually limited not by diffraction but by other effects such as turbulence in the atmosphere. The resolution of a high-quality microscope, on the other hand, normally is limited by diffraction; microscope objectives are complex compound lenses containing many elements of small diameter (since f is small), thus reducing aberrations.

FIGURE 25-32 The 300-meter radiotelescope in Arecibo, Puerto Rico, uses radio waves (Fig. 22-8) instead of visible light.

NOTE In both cases, we determined the limit set by diffraction. The resolution for a visible-light Earth-bound telescope is not this good because of aberrations and, more importantly, turbulence in the atmosphere. In fact, large-diameter objectives are not justified by increased resolution, but by their greater light-gathering ability—they allow more light in, so fainter objects can be seen. Radiotelescopes are not hindered by atmospheric turbulence, and the resolution found in (b) is a good estimate.

Diffraction sets an ultimate limit on the detail that can be seen on any object. In Eq. 25–8 for resolving power, the focal length of a lens cannot practically be made less than (approximately) the radius of the lens, and even that is very difficult (see the lensmaker's equation, Eq. 23-10). In this best case, Eq. 25-8 gives, with $f \approx D/2$,

$$
RP \approx \frac{\lambda}{2}.
$$
 (25-9)

Thus we can say, to within a factor of 2 or so, that

it is not possible to resolve detail of objects smaller than the wavelength of the radiation being used.

This is an important and useful rule of thumb.

Compound lenses in microscopes are now designed so well that the actual limit on resolution is often set by diffraction—that is, by the wavelength of the light used. To obtain greater detail, one must use radiation of shorter wavelength. The use of UV radiation can increase the resolution by a factor of perhaps 2. Far more important, however, was the discovery in the early twentieth century that electrons have wave properties (Chapter 27) and that their wavelengths can be very small. The wave nature of electrons is utilized in the electron microscope (Section 27–9), which can magnify 100 to 1000 times more than a visible-light microscope because of the much shorter wavelengths. X-rays, too, have very short wavelengths and are often used to study objects in great detail (Section 25–11).

25-9 Resolution of the Human Eye and **Useful Magnification**

The resolution of the human eye is limited by several factors, all of roughly the same order of magnitude. The resolution is best at the fovea, where the cone spacing is smallest, about $3 \mu m$ (= 3000 nm). The diameter of the pupil varies from about 0.1 cm to about 0.8 cm. So for $\lambda = 550$ nm (where the eye's sensitivity is greatest), the diffraction limit is about $\theta \approx 1.22\lambda/D \approx 8 \times 10^{-5}$ rad to 6×10^{-4} rad. The eye is about 2 cm long, giving a resolving power (Eq. 25–8) of $s \approx (2 \times 10^{-2} \text{ m})(8 \times 10^{-5} \text{ rad}) \approx 2 \mu \text{m}$ at best, to about 15 μ m at worst (pupil small). Spherical and chromatic aberration also limit the resolution to about 10 μ m. The net result is that the eye can resolve objects whose angular separation is about

$$
5\times10^{-4}\,\mathrm{rad}
$$

at best. This corresponds to objects separated by 1 cm at a distance of about 20 m.

The typical near point of a human eye is about 25 cm. At this distance, the eye can just resolve objects that are $(25 \text{ cm})(5 \times 10^{-4} \text{ rad}) \approx 10^{-4} \text{ m} = \frac{1}{10} \text{ mm}$ apart. Since the best light microscopes can resolve objects no smaller than about 200 nm at best (Eq. 25–9 for violet light, $\lambda = 400$ nm), the useful magnification $[=$ (resolution by naked eye)/(resolution by microscope)] is limited to about

$$
\frac{10^{-4} \text{ m}}{200 \times 10^{-9} \text{ m}} \approx 500 \times.
$$

In practice, magnifications of about $1000 \times$ are often used to minimize eyestrain. Any greater magnification would simply make visible the diffraction pattern produced by the microscope objective.

 π) PHYSICS

25-10 Specialty Microscopes and Contrast

All the resolving power a microscope can attain will be useless if the object to be seen cannot be distinguished from the background. The difference in brightness between the image of an object and the image of the surroundings is called contrast. Achieving high contrast is an important problem in microscopy and other forms of imaging. The problem arises in biology, for example, because cells consist largely of water and are almost uniformly transparent to light. We now briefly discuss two special types of microscope that can increase contrast: the interference and phase-contrast microscopes.

An interference microscope makes use of the wave properties of light in a direct way to increase contrast in a transparent object. Consider a transparent object—say, a bacterium in water (Fig. 25–33). Light enters uniformly from the left and is coherent (in phase) at all points such as a and b. If the object is as transparent as the water, the beam leaving at d will be as bright as that at c. There will be no contrast and the object will not be seen. However, if the object's refractive index is slightly different from that of the surrounding medium, the wavelength within the object will be altered as shown. Hence light waves at points c and d will differ in phase, if not in amplitude. The interference microscope changes this difference in phase into a difference of amplitude which our eyes can detect. Light that passes through the sample is superimposed onto a reference beam that does not pass through the object, so that they interfere. One way of doing this is shown in Fig. 25–34. Light from a source is split into two equal beams by a half-silvered mirror, $MS₁$. One beam passes through the object, and the second (comparison beam) passes through an identical system without the object. The two meet again and are superposed by the half-silvered mirror MS_2 before entering the eyepiece and the eye. The path length (and amplitude) of the comparison beam is adjustable so that the background can be dark; that is, full destructive interference occurs. Light passing through the object (beam bd in Fig. 25–33) will also interfere with the comparison beam. But because of its different phase, the interference will not be completely destructive. Thus it will appear brighter than the background. Where the object varies in thickness, the phase difference between beams ac and bd in Fig. 25–33 will be different, thus affecting the amount of interference. Hence variation in the thickness of the object will appear as variations in brightness in the image.

A phase-contrast microscope also makes use of interference and differences in phase to produce a high-contrast image. Contrast is achieved by a circular glass phase plate that has a groove (or a raised portion) in the shape of a ring, positioned so undeviated source rays pass through it, but rays deviated by the object do not pass through this ring. Because the rays deviated by the object travel through a different thickness of glass than the undeviated source rays, the two can be out of phase and can interfere destructively at the object image plane. Thus the image of the object can contrast sharply with the background. Phase-contrast microscope images tend to have "halos" around them (as a result of diffraction from the phase-plate opening), so care must be taken in the interpretation of images.

APPLIED

Phase-contrast microscope

25-11 X-Rays and X-Ray Diffraction

In 1895, W. C. Roentgen (1845–1923) discovered that when electrons were accelerated by a high voltage in a vacuum tube and allowed to strike a glass or metal surface inside the tube, fluorescent minerals some distance away would glow, and photographic film would become exposed. Roentgen attributed these effects to a new type of radiation (different from cathode rays). They were given the name **X-rays** after the algebraic symbol x , meaning an unknown quantity. He soon found that X-rays penetrated through some materials better than through others, and within a few weeks he presented the first X-ray photograph (of his wife's hand). The production of X-rays today is usually done in a tube (Fig. 25–35) similar to Roentgen's, using voltages of typically 30 kV to 150 kV.

Investigations into the nature of X-rays indicated they were not charged particles (such as electrons) since they could not be deflected by electric or magnetic fields. It was suggested that they might be a form of invisible light. However, they showed no diffraction or interference effects using ordinary gratings. Indeed, if their wavelengths were much smaller than the typical grating spacing of 10^{-6} m (= 10^3 nm), no effects would be expected. Around 1912, Max von Laue (1879–1960) suggested that if the atoms in a crystal were arranged in a regular array (see Fig. $13-2a$), such a crystal might serve as a diffraction grating for very short wavelengths on the order of the spacing between atoms, estimated to be about 10^{-10} m (= 10^{-1} nm). Experiments soon showed that X-rays scattered from a crystal did indeed show the peaks and valleys of a diffraction pattern (Fig. 25–36). Thus it was shown, in a single blow, that X-rays have a wave nature and that atoms are arranged in a regular way in crystals. Today, X-rays are recognized as electromagnetic radiation with wavelengths in the range of about 10^{-2} nm to 10 nm, the range readily produced in an X-ray tube.

We saw in Sections 25-7 and 25-8 that light of shorter wavelength provides greater resolution when we are examining an object microscopically. Since X-rays have much shorter wavelengths than visible light, they should in principle offer much greater resolution. However, there seems to be no effective material to use as lenses for the very short wavelengths of X-rays. Instead, the clever but complicated technique of **X-ray diffraction** (or **crystallography**) has proved very effective for examining the microscopic world of atoms and molecules. In a simple crystal such as NaCl, the atoms are arranged in an orderly cubical fashion, Fig. $25-37$, with atoms spaced a distance d apart. Suppose that a beam of X-rays is incident on the crystal at an angle ϕ to the surface, and that the two rays shown are reflected from two subsequent planes of atoms as shown. The two rays will constructively interfere if the extra distance ray I travels is a whole number of wavelengths farther than the distance ray II travels. This extra distance is $2d \sin \phi$. Therefore, constructive interference will occur when

$$
m\lambda = 2d \sin \phi, \qquad m = 1, 2, 3, \cdots,
$$
 (25-10)

where *m* can be any integer. (Notice that ϕ is *not* the angle with respect to the normal to the surface.) This is called the **Bragg equation** after W. L. Bragg $(1890-1971)$, who derived it and who, together with his father W. H. Bragg (1862–1942), developed the theory and technique of X-ray diffraction by crystals in 1912–1913. If the X-ray wavelength is known and the angle ϕ is measured, the distance d between atoms can be obtained. This is the basis for X-ray crystallography.

FIGURE 25-35 X-ray tube. Electrons emitted by a heated filament in a vacuum tube are accelerated by a high voltage. When they strike the surface of the anode, the "target," X-rays are emitted.

FIGURE 25-36 This X-ray diffraction pattern is one of the first observed by Max von Laue in 1912 when he aimed a beam of X-rays at a zinc sulfide crystal. The diffraction pattern was detected directly on a photographic plate.

Bragg equation

FIGURE 25-38 X-rays can be diffracted from many possible planes within a crystal.

Actual X-ray diffraction patterns are quite complicated. First of all, a crystal is a three-dimensional object, and X-rays can be diffracted from different planes at different angles within the crystal, as shown in Fig. 25–38. Although the analysis is complex, a great deal can be learned about any substance that can be put in crystalline form. If the substance is not a single crystal but a mixture of many tiny crystals—as in a metal or a powder—then instead of a series of spots, as in Fig. $25-36$, a series of circles is obtained, Fig. $25-39$, each corresponding to diffraction of a certain order m from a particular set of parallel planes.

FIGURE 25-40 X-ray diffraction photo of DNA molecules taken by Rosalind Franklin in the early 1950s. The cross of spots suggested that DNA is a helix.

∖РНҮSІСS APPLIED Normal X-ray image

CAUTION X-ray images are a sort of shadow; no lenses are involved

X-ray diffraction has been very useful in determining the structure of biologically important molecules, such as the double helix structure of DNA, worked out by James Watson and Francis Crick in 1953. See Fig. 25-40, and for models of the double helix, Figs. 16–44a and 16–45. Around 1960, the first detailed structure of a protein molecule, myoglobin, was elucidated with the aid of X-ray diffraction. Soon the structure of an important constituent of blood, hemoglobin, was worked out, and since then the structures of a great many molecules have been determined with the help of X-rays.

25-12 X-Ray Imaging and Computed Tomography (CT Scan)

* Normal X-ray Image

For a conventional medical or dental X-ray photograph, the X-rays emerging from the tube (Fig. 25–35) pass through the body and are detected on photographic film or a fluorescent screen, Fig. 25-41. The rays travel in very nearly straight lines through the body with minimal deviation since at X-ray wavelengths there is little diffraction or refraction. There is absorption (and scattering), however; and the difference in absorption by different structures in the body is what gives rise to the image produced by the transmitted rays. The less the absorption, the greater the transmission and the darker the film. The image is, in a sense, a "shadow" of what the rays have passed through. The X-ray image is *not* produced by focusing rays with lenses as for the instruments discussed earlier in this Chapter.

FIGURE 25-41 Conventional X-ray imaging, which is essentially shadowing

FIGURE 25-42 Tomographic imaging: the X-ray source and detector move together across the body, the transmitted intensity being measured at a large number of points. Then the source-detector assembly is rotated slightly (say, 1°) and another scan is made. This process is repeated for perhaps 180 $^{\circ}$. The computer reconstructs the image of the slice and it is presented on a TV monitor.

* Tomography Images (CT)

In conventional X-ray images, the entire thickness of the body is projected onto the film; structures overlap and in many cases are difficult to distinguish. In the 1970s, a revolutionary new X-ray technique was developed called computed **tomography** (CT), which produces an image of a *slice* through the body. (The word **tomography** comes from the Greek: $tomos = slice$, $graph = picture$.) Structures and lesions previously impossible to visualize can now be seen with remarkable clarity. The principle behind CT is shown in Fig. 25–42: a thin collimated beam of X-rays (to "collimate" means to "make straight") passes through the body to a detector that measures the transmitted intensity. Measurements are made at a large number of points as the source and detector are moved past the body together. The apparatus is then rotated slightly about the body axis and again scanned; this is repeated at (perhaps) 1° intervals for 180° . The intensity of the transmitted beam for the many points of each scan, and for each angle, are sent to a computer that reconstructs the image of the slice. Note that the imaged slice is perpendicular to the long axis of the body. For this reason, CT is sometimes called computerized axial tomography (CAT), although the abbreviation CAT, as in CAT scan, can also be read as computer-assisted tomography.

The use of a single detector as in Fig. 25–42 would require a few minutes for the many scans needed to form a complete image. Much faster scanners use a fan beam, Fig. 25–43a, in which beams passing through the entire cross section of the body are detected simultaneously by many detectors. The source and detectors are then rotated about the patient, and an image requires only a few seconds. Even faster, and therefore useful for heart scans, are fixed source machines wherein an electron beam is directed (by magnetic fields) to tungsten targets surrounding the patient, creating the X-rays. See Fig. 25-43b.

CAT scans

FIGURE $25-43$ (a) Fan-beam scanner. Rays transmitted through the entire body are measured simultaneously at each angle. The source and detector rotate to take measurements at different angles. In another type of fan-beam scanner, there are detectors around the entire 360° of the circle which remain fixed as the source moves. (b) In another type, a beam of electrons from the source is directed by magnetic fields at tungsten targets surrounding the patient.

 (b)

FIGURE 25-44 Two CT images. with different resolutions, each showing a cross section of a brain. Photo (a) is of low resolution; photo (b), of higher resolution, shows a brain tumor (dark area on the right).

Image reconstruction

FIGURE 25-45 A simple 2×2 image showing true absorption values and measured projections.

* Image Formation

But how is the image formed? We can think of the slice to be imaged as being divided into many tiny picture elements (or pixels), which could be squares. (See, for example, Fig. 24-49.) For CT, the width of each pixel is chosen according to the width of the detectors and/or the width of the X-ray beams, and this determines the resolution of the image, which might be 1 mm. An X-ray detector measures the intensity of the transmitted beam. Subtracting this value from the intensity of the beam at the source, yields the total absorption (called a "projection") along that beam line. Complicated mathematical techniques are used to analyze all the absorption projections for the huge number of beam scans measured (see the next subsection), obtaining the absorption at each pixel and assigning each a "grayness value" according to how much radiation was absorbed. The image is made up of tiny spots (pixels) of varying shades of gray. Often the amount of absorption is color-coded. The colors in the resulting "false-color" image have nothing to do, however, with the actual color of the object.

Figure 25-44 illustrates what actual CT images look like. It is generally agreed that CT scanning has revolutionized some areas of medicine by providing much less invasive, and/or more accurate, diagnosis.

Computed tomography can also be applied to ultrasound imaging (Section $12-9$) and to emissions from radioisotopes and nuclear magnetic resonance (Sections 31–8 and 31–9).

* Tomographic Image Reconstruction

How can the "grayness" of each pixel be determined even though all we can measure is the total absorption along each beam line in the slice? It can be done only by using the many beam scans made at a great many different angles. Suppose the image is to be an array of 100×100 elements for a total of 10^4 pixels. If we have 100 detectors and measure the absorption projections at 100 different angles, then we get $10⁴$ pieces of information. From this information, an image can be reconstructed, but not precisely. If more angles are measured, the reconstruction of the image can be done more accurately.

To suggest how mathematical reconstruction is done, we consider a very simple case using the "iterative" technique ("to iterate" is from the Latin "to repeat"). Suppose our sample slice is divided into the simple 2×2 pixels as shown in Fig. 25–45. The number in each pixel represents the amount of absorption by the material in that area (say, in tenths of a percent): that is, 4 represents twice as much absorption as 2. But we cannot directly measure these valuesthey are the unknowns we want to solve for. All we can measure are the projections—the total absorption along each beam line—and these are shown in the diagram as the sum of the absorptions for the pixels along each line at four different angles. These projections (given at the tip of each arrow) are what we can measure, and we now want to work back from them to see how close we can get to the true absorption value for each pixel. We start our analysis with each pixel being assigned a zero value, Fig. 25–46a. In the iterative technique, we use the projections to estimate the absorption value in each square, and repeat for each angle. The angle 1 projections are 7 and 13. We divide each of these equally between their two squares: each square in the left column gets $3\frac{1}{2}$ (half of 7), and each square in the right column gets $6\frac{1}{2}$ (half of 13); see Fig. 25–46b. Next we use

the projections at angle 2. We calculate the difference between the measured projections at angle 2 (6 and 14) and the projections based on the previous estimate (top row: $3\frac{1}{2} + 6\frac{1}{2} = 10$; same for bottom row). Then we distribute this difference equally to the squares in that row. For the top row, we have

$$
3\frac{1}{2} + \frac{6 - 10}{2} = 1\frac{1}{2}
$$
 and $6\frac{1}{2} + \frac{6 - 10}{2} = 4\frac{1}{2}$;

and for the bottom row,

$$
3\frac{1}{2} + \frac{14 - 10}{2} = 5\frac{1}{2}
$$
 and $6\frac{1}{2} + \frac{14 - 10}{2} = 8\frac{1}{2}$

These values are inserted as shown in Fig. 25-46c. Next, the projection at angle 3 gives (upper left) $1\frac{1}{2} + \frac{11 - 10}{2} = 2$ and (lower right) $8\frac{1}{2} + \frac{11 - 10}{2} = 9$; and that for angle 4 gives

(lower left) $5\frac{1}{2} + \frac{9-10}{2} = 5$ and (upper right) $4\frac{1}{2} + \frac{9-10}{2} = 4$.

The result, shown in Fig. 25-46d, corresponds exactly to the true values. (In real situations, the true values are not known, which is why these computer techniques are required.) To obtain these numbers exactly, we used six pieces of information (two each at angles 1 and 2, one each at angles 3 and 4). For the much larger number of pixels used for actual images, exact values are generally not attained. Many iterations may be needed, and the calculation is considered sufficiently precise when the difference between calculated and measured projections is sufficiently small. The above example illustrates the "convergence" of the process: the first iteration (b to c in Fig. $25-46$) changed the values by 2, the last iteration (c to d) by only $\frac{1}{2}$.

Summary

 λ

A camera lens forms an image on film, or on a chargecoupled device in a digital camera, by allowing light in through a shutter. The lens is focused by moving it relative to the film, and its f -stop (or lens opening) must be adjusted for the brightness of the scene and the chosen shutter speed. The f-stop is defined as the ratio of the focal length to the diameter of the lens opening.

The human eye also adjusts for the available light-by opening and closing the iris. It focuses not by moving the lens, but by adjusting the shape of the lens to vary its focal length. The image is formed on the retina, which contains an array of receptors known as rods and cones.

Diverging eye-glass or contact lenses are used to correct the defect of a nearsighted eye, which cannot focus well on distant objects. Converging lenses are used to correct for defects in which the eye cannot focus on close objects.

A simple magnifier is a converging lens that forms a virtual image of an object placed at (or within) the focal point. The angular magnification, when viewed by a relaxed normal eye, is

$$
M = \frac{N}{f},\tag{25-2a}
$$

where f is the focal length of the lens and N is the near point of the eye (25 cm for a "normal" eye).

An astronomical telescope consists of an objective lens or mirror, and an eyepiece that magnifies the real image formed by the objective. The **magnification** is equal to the ratio of the objective and eyepiece focal lengths, and the image is inverted:

$$
M = -\frac{f_0}{f_c}.\tag{25-3}
$$

^{[*}A compound **microscope** also uses objective and eyepiece lenses, and the final image is inverted. The total magnification is the product of the magnifications of the two lenses and is approximately

$$
M \approx \frac{Nl}{f_{\rm e}f_{\rm o}},\tag{25-6b}
$$

where l is the distance between the lenses, N is the near point of the eye, and f_0 and f_c are the focal lengths of objective and eyepiece, respectively.]

Microscopes, telescopes, and other optical instruments are limited in the formation of sharp images by lens aberrations. These include spherical aberration, in which rays passing through the edge of a lens are not focused at the same point as those that pass near the center; and chromatic aberration, in which different colors are focused at different points. Compound lenses, consisting of several elements, can largely correct for aberrations.

The wave nature of light also limits the sharpness, or resolution, of images. Because of diffraction, it is not possible to discern details smaller than the wavelength of the radiation being used. This limits the useful magnification of a light microscope to about 500×.

 $[*X-rays are a form of electromagnetic radiation of very$ short wavelength. They are produced when high-speed electrons, accelerated by high voltage in an evacuated tube, strike a glass or metal target.]

[*Computed tomography (CT or CAT scans) uses many narrow X-ray beams through a section of the body to construct an image of that section.]

Questions

- 1. Why is the depth of field greater, and the image sharper, when a camera lens is "stopped down" to a larger f -number? Ignore diffraction.
- 2. Describe how diffraction affects the statement of Question 1. [*Hint*: see Eq. 24–3 or $25-7.$]
- 3. Why must a camera lens be moved farther from the film to focus on a closer object?
- 4. Why are bifocals needed mainly by older persons and not generally by younger people?
- 5. Will a nearsighted person who wears corrective lenses in her glasses be able to see clearly underwater when wearing those glasses? Use a diagram to show why or why not.
- 6. You can tell whether a person is nearsighted or farsighted by looking at the width of the face through their glasses. If the person's face appears narrower through the glasses (Fig. $25-47$), is the person farsighted or nearsighted?

FIGURE 25-47 Question 6.

- 7. In attempting to discern distant details, people will sometimes squint. Why does this help?
- 8. Is the image formed on the retina of the human eye upright or inverted? Discuss the implications of this for our perception of objects.
- 9. The human eve is much like a camera-vet, when a camera shutter is left open and the camera is moved, the image will be blurred; but when you move your head with your eyes open, you still see clearly. Explain.
- 10. Reading glasses use converging lenses. A simple magnifier is also a converging lens. Are reading glasses therefore magnifiers? Discuss the similarities and differences between converging lenses as used for these two different purposes.
- *11. Inexpensive microscopes for children's use usually produce images that are colored at the edges. Why?
- *12. Spherical aberration in a thin lens is minimized if rays are bent equally by the two surfaces. If a planoconvex lens is used to form a real image of an object at infinity, which surface should face the object? Use ray diagrams to show why.
- *13. Which aberrations present in a simple lens are not present (or are greatly reduced) in the human eye?
- *14. Explain why chromatic aberration occurs for thin lenses but not for mirrors.
- 15. By what factor can you improve resolution, other things being equal, if you use blue light ($\lambda = 450 \text{ nm}$) rather than red (700 nm) ?
- 16. Give at least two advantages for the use of large reflecting mirrors in astronomical telescopes.
- 17. Which color of visible light would give the best resolution in a microscope? Explain.
- 18. Atoms have diameters of about 10^{-8} cm. Can visible light be used to "see" an atom? Explain.

Problems

25-1 Camera

- 1. (I) A 55-mm-focal-length lens has f -stops ranging from $f/1.4$ to $f/22$. What is the corresponding range of lens diaphragm diameters?
- 2. (I) A television camera lens has a 14-cm focal length and a lens diameter of 6.0 cm. What is its f-number?
- 3. (I) A light meter reports that a camera setting of $\frac{1}{250}$ s at $f/5.6$ will give a correct exposure. But the photographer wishes to use $f/11$ to increase the depth of field. What should the shutter speed be?
- 4. (I) A properly exposed photograph is taken at $f/16$ and $\frac{1}{60}$ s. What lens opening would be required if the shutter speed were $\frac{1}{1000}$ s?
- 5. (II) If an $f = 135$ -mm telephoto lens is designed to cover object distances from 1.2 m to ∞ , over what distance must the lens move relative to the plane of the film?
- 6. (II) A 200-mm-focal-length lens can be adjusted so that it is 200.0 mm to 206.0 mm from the film. For what range of object distances can it be adjusted?
- 7. (II) A nature photographer wishes to photograph a 28-mtall tree from a distance of 58 m. What focal-length lens should be used if the image is to fill the 24-mm height of the film?
- 8. (II) A "pinhole" camera uses a tiny pinhole instead of a lens. Show, using ray diagrams, how reasonably sharp images can be formed using such a pinhole camera. In particular, consider two point objects 2.0 cm apart that are 1.0 m from a 1.0-mm-diameter pinhole. Show that on a piece of film 7.0 cm behind the pinhole the two objects produce two separate circles that do not overlap.
- 9. (III) Suppose that a correct exposure is $\frac{1}{250}$ s at $f/11$. Under the same conditions, what exposure time would be needed for a pinhole camera (Problem 8) if the pinhole diameter is 1.0 mm and the film is 7.0 cm from the hole?

25-2 Eye and Corrective Lenses

10. (I) A human eyeball is about 2.0 cm long, and the pupil has a maximum diameter of about 8.0 mm. What is the "speed" of this lens?

- 11. (I) If the nearsighted person in Example 25–6 wore contact lenses corrected for the far point (= ∞), show that the near point would be 41 cm. (Would glasses be better in this case?)
- 12. (II) Reading glasses of what power are needed for a person whose near point is 115 cm, so that he can read a computer screen at 55 cm? Assume a lens-eye distance of 1.8 cm.
- 13. (II) A person has a far point of 14 cm. What power glasses would correct this vision if the glasses were placed 2.0 cm from the eye? What power contact lenses, placed on the eye, would the person need?
- 14. (II) A person struggles to read by holding a book at arm's length, a distance of 45 cm away (= near point). What power of reading glasses should be prescribed for him. assuming they will be placed 2.0 cm from the eve and he wants to read at the normal near point of 25 cm?
- 15. (II) A person's left eye is corrected by a -3.50 -diopter lens, 2.0 cm from the eye. (a) Is this person's left eye near- or farsighted? (b) What is this eye's far point without glasses?
- 16. (II) A person's right eye can see objects clearly only if they are between 25 cm and 75 cm away. (a) What power of contact lens is required so that objects far away are sharp? (b) What will be the near point with the lens in place?
- 17. (II) About how much longer is the nearsighted eye in Example 25-6 than the 2.0 cm of a normal eye?
- 18. (II) One lens of a nearsighted person's eyeglasses has a focal length of -22.0 cm, and the lens is 1.8 cm from the eye. If the person switches to contact lenses that are placed directly on the eye, what should be the focal length of the corresponding contact lens?
- 19. (II) What is the focal length of the eye-lens system when viewing an object (a) at infinity, and (b) 33 cm from the eye? Assume that the lens-retina distance is 2.0 cm.
- 20. (III) A nearsighted person has near and far points of 10.0 and 20.0 cm, respectively. If she puts on contact lenses with power $P = -4.00$ D, what are her new near and far points?

25-3 Magnifying Glass

- 21. (I) What is the magnification of a lens used with a relaxed eye if its focal length is 12 cm?
- 22. (I) What is the focal length of a magnifying glass of $3.5\times$ magnification for a relaxed normal eye?
- 23. (I) A magnifier is rated at $2.5 \times$ for a normal eye focusing on an image at the near point. (a) What is its focal length? (b) What is its focal length if the $2.5\times$ refers to a relaxed eye?
- 24. (II) Sherlock Holmes is using a 9.00-cm-focal-length lens as his magnifying glass. To obtain maximum magnification, where must the object be placed (assume a normal eye), and what will be the magnification?
- 25. (II) A 3.30-mm-wide beetle is viewed with a 9.50-cm-focallength lens. A normal eye views the image at its near point. Calculate (a) the angular magnification, (b) the width of the image, and (c) the object distance from the lens.
- 26. (II) A small insect is placed 5.55 cm from a $+6.00$ -cmfocal-length lens. Calculate (a) the position of the image, and (b) the angular magnification.
- $27.$ (II) A magnifying glass with a focal length of 8.5 cm is used to read print placed at a distance of 7.5 cm. Calculate (a) the position of the image; (b) the angular magnification.
- 28. (III) A magnifying glass is rated at $3.0 \times$ for a normal eye that is relaxed. What would be the magnification of this lens for a relaxed eye whose near point is (a) 55 cm, and (b) 16 cm? Explain the differences.

25-4 Telescopes

- 29. (I) What is the magnification of an astronomical telescope whose objective lens has a focal length of 76 cm and whose eyepiece has a focal length of 2.8 cm? What is the overall length of the telescope when adjusted for a relaxed eye?
- 30. (I) The overall magnification of an astronomical telescope is desired to be $25\times$. If an objective of 78-cm focal length is used, what must be the focal length of the eyepiece? What is the overall length of the telescope when adjusted for use by the relaxed eye?
- 31. (I) An 8.0× binocular has 2.8-cm-focal-length eyepieces. What is the focal length of the objective lenses?
- 32. (II) An astronomical telescope has an objective with focal length 85 cm and a $+35 \text{ -D}$ evepiece. What is the total magnification?
- 33. (II) An astronomical telescope has its two lenses spaced 75.2 cm apart. If the objective lens has a focal length of 74.5 cm, what is the magnification of this telescope? Assume a relaxed eye.
- 34. (II) A Galilean telescope adjusted for a relaxed eve is 32.8 cm long. If the objective lens has a focal length of 36.0 cm, what is the magnification?
- 35. (II) What is the magnifying power of an astronomical telescope using a reflecting mirror whose radius of curvature is 6.0 m and an eyepiece whose focal length is 3.2 cm?
- 36. (II) The Moon's image appears to be magnified $120 \times$ by a reflecting astronomical telescope with an eyepiece having a focal length of 3.2 cm. What are the focal length and radius of curvature of the main (objective) mirror?
- 37. (II) A $170\times$ astronomical telescope is adjusted for a relaxed eye when the two lenses are 1.25 m apart. What is the focal length of each lens?
- 38. (III) A reflecting telescope (Fig. $25-21b$) has a radius of curvature of 3.0 m for its objective mirror and a radius of curvature of -1.50 m for its eyepiece mirror. If the distance between the two mirrors is 0.90 m, how far in front of the eyepiece should you place the photographic film to record the image of a star?

* 25-5 Microscope

***39.** (I) A microscope uses an eyepiece with a focal length of 1.40 cm. Using a normal eye with a final image at infinity, the tube length is 17.5 cm and the focal length of the objective lens is 0.65 cm. What is the magnification of the microscope?

- * 40. (I) A 620× microscope uses a 0.40-cm-focal-length objective lens. If the tube length is 17.5 cm, what is the focal length of the eyepiece? Assume a normal eye and that the final image is at infinity.
- *41. (I) A 17-cm-long microscope has an evepiece with a focal length of 2.5 cm and an objective with a focal length of 0.28 cm. What is the approximate magnification?
- * 42. (II) A microscope has a $12.0 \times$ eyepiece and a 59.0 \times objective lens 20.0 cm apart. Calculate (a) the total magnification, (b) the focal length of each lens, and (c) where the object must be for a normal relaxed eye to see it in focus.
- $*$ 43. (II) A microscope has a 1.8-cm-focal-length evepiece and a 0.80-cm objective lens. Assuming a relaxed normal eye, calculate (a) the position of the object if the distance between the lenses is 16.0 cm, and (b) the total magnification.
- *44. (II) Repeat Problem 43 assuming that the final image is located 25 cm from the eyepiece (near point of a normal eye).
- *45. (III) The eyepiece of a compound microscope has a focal length of 2.70 cm, and the objective lens has $f = 0.740$ cm. If an object is placed 0.790 cm from the objective lens, calculate (a) the distance between the lenses when the microscope is adjusted for a relaxed eye, and (b) the total magnification.

* 25-6 Aberrations

- * 46. (II) An achromatic lens is made of two very thin lenses, placed in contact, that have focal lengths of $f_1 = -28$ cm and $f_2 = +23$ cm. (a) Is the combination converging or diverging? (b) What is the net focal length?
- * 47. (III) Let's examine spherical aberration in a particular situation. A planoconvex lens of index of refraction 1.50 and radius of curvature $R = 12.0$ cm is shown in Fig. 25-48. Consider an incoming ray parallel to the principal axis and a height h above it as shown. Determine the distance d , from the flat face of the lens, to where this ray crosses the principal axis if (a) $h = 1.0$ cm, and (b) $h = 6.0$ cm. (c) How far apart are these "focal points"? (d) What is the radius of the "circle of least confusion" produced by the $h = 6.0$ -cm ray at the "focal point" for $h = 1.0$ cm?

FIGURE 25-48 Problem 47.

25-7 to 25-9 Resolution

- 48. (I) What is the angular resolution limit (degrees) set by diffraction for the 100-in. (254-cm mirror diameter) Mt. Wilson telescope ($\lambda = 550$ nm)?
- 49. (II) Suppose that you wish to construct a telescope that can resolve features 7.0 km across on the Moon, 384,000 km away. You have a 2.0-m-focal-length objective lens whose diameter is 11.0 cm. What focal-length eyepiece is needed if your eye can resolve objects 0.10 mm apart at a distance of 25 cm? What is the resolution limit (radians) set by the size of the objective lens (that is, by diffraction)? Use $\lambda = 550$ nm.
- 50. (II) The normal lens on a 35-mm camera has a focal length of 50.0 mm. Its aperture diameter varies from a maximum of 25 mm ($f/2$) to a minimum of 3.0 mm $(f/16)$. Determine the resolution limit set by diffraction for $f/2$ and $f/16$. Specify as the number of lines per millimeter resolved on the film. Take $\lambda = 550$ nm.
- 51. (II) Two stars 15 light-years away are barely resolved by a 55-cm (mirror diameter) telescope. How far apart are the stars? Assume $\lambda = 550 \text{ nm}$ and that the resolution is limited by diffraction.
- 52. (II) (a) How far away can a human eye distinguish two car headlights 2.0 m apart? Consider only diffraction effects and assume an eye pupil diameter of 5.0 mm and a wavelength of 550 nm . (b) What is the minimum angular separation an eve could resolve when viewing two stars, considering only diffraction effects? In reality, it is about $1'$ of arc. Why is it not equal to your answer in (b) ?
- 53. (II) The Earth and Moon are separated by about 400×10^6 m. When Mars is 8×10^{10} m from Earth, could a person standing on Mars resolve the Earth and its Moon as two separate objects without a telescope? Assume a pupil diameter of 5 mm and $\lambda = 550$ nm.

* 25-11 X-rays

- * 54. (II) X-rays of wavelength 0.133 nm fall on a crystal whose atoms, lying in planes, are spaced 0.280 nm apart. At what angle ϕ (relative to the surface, Fig. 25–37) must the X-rays be directed if the first diffraction maximum is to be observed?
- * 55. (II) X-rays of wavelength 0.0973 nm are directed at an unknown crystal. The second diffraction maximum is recorded when the X-rays are directed at an angle of 23.4° relative to the crystal surface. What is the spacing between crystal planes?
- * 56. (II) First-order Bragg diffraction is observed at 25.2° related to the crystal surface, with spacing between atoms of 0.24 nm. (a) At what angle will second order be observed? (b) What is the wavelength of the X-rays?

* 25-12 Computed Tomography

* 57. (II) (a) Suppose for a conventional X-ray image that the X-ray beam consists of parallel rays. What would be the magnification of the image? (b) Suppose, instead, the X-rays come from a point source (as in Fig. 25-41) that is 15 cm in front of a human body 25 cm thick, and the film is pressed against the person's back. Determine and discuss the range of magnifications that results.

General Problems

- 58. Sam purchases $+3.50$ -diopter eyeglasses which correct his faulty vision to put his near point at 25 cm. (Assume he wears the lenses 2.0 cm from his eyes.) (a) Calculate the focal length of Sam's glasses. (b) Calculate Sam's near point without glasses. (c) Pam, who has normal eyes with near point at 25 cm, puts on Sam's glasses. Calculate Pam's near point with Sam's glasses on.
- 59. As early morning passed toward midday, and the sunlight got more intense, a photographer noted that, if she kept her shutter speed constant, she had to change the f-number from $f/5.6$ to $f/22$. By what factor had the sunlight intensity increased during that time?
- 60. Show that for objects very far away (assume infinity), the magnification of a camera lens is proportional to its focal length.
- 61. For a camera equipped with a 50-mm-focal-length lens, what is the object distance if the image height equals the object height? How far is the object from the film?
- 62. A woman can see clearly with her right eve only when objects are between 45 cm and 155 cm away. Prescription bifocals should have what powers so that she can see distant objects clearly (upper part) and be able to read a book 25 cm away (lower part) with her right eye? Assume that the glasses will be 2.0 cm from the eye.
- 63. A child has a near point of 15 cm. What is the maximum magnification the child can obtain using an 8.0-cm-focallength magnifier? What magnification can a normal eye obtain with the same lens? Which person sees more detail?
- 64. What is the magnifying power of a $+4.0$ -D lens used as a magnifier? Assume a relaxed normal eye.
- 65. A physicist lost in the mountains tries to make a telescope using the lenses from his reading glasses. They have powers of $+2.0$ D and $+4.5$ D, respectively. (a) What maximum magnification telescope is possible? (b) Which lens should be used as the eyepiece?
- 66. A 50-year-old man uses $+2.5$ -diopter lenses to read a newspaper 25 cm away. Ten years later, he must hold the paper 35 cm away to see clearly with the same lenses. What power lenses does he need now in order to hold the paper 25 cm away? (Distances are measured from the lens.)
- 67. Spy planes fly at extremely high altitudes (25 km) to avoid interception. Their cameras are reportedly able to discern features as small as 5 cm. What must be the minimum aperture of the camera lens to afford this resolution? (Use $\lambda = 550$ nm.)
- 68. When shooting pictures at very short distances, exposure times must be increased because of the increased distance of the lens from the film for a focused image. (a) Show that when the object is so close to the camera that the image height equals the object height, the exposure time must be four times longer (or $2 f$ -stops) than when the object is a long distance away (say, ∞), given the same illumination and f-stop. (b) Show that if d_0 is at least four or five times the focal length f of the lens, the exposure time is increased by less than half an f -stop relative to the same object being a great distance away.
- 69. The objective lens and the evepiece of a telescope are spaced 85 cm apart. If the evepiece is $+23$ diopters, what is the total magnification of the telescope?
- 70. The Hubble Space Telescope, with an objective diameter of 2.4 m, is viewing the Moon. Estimate the minimum distance between two objects on the Moon that the Hubble can distinguish. Consider diffraction of light of wavelength 550 nm. Assume the Hubble is near the Earth.
- 71. Two converging lenses, one with $f = 4.0$ cm and the other with $f = 44$ cm, are made into a telescope. (a) What are the length and magnification? Which lens should be the evepiece? (b) Assume these lenses are now combined to make a microscope; if the magnification needs to be 25×, how long would the microscope be?
- 72. An astronomical telescope has a magnification of 8.0. If the two lenses are 28 cm apart, determine the focal length of each lens.
- 73. You want to design a spy satellite to photograph license plate numbers. Assuming it is necessary to resolve points separated by 5 cm with 550-nm light, and that the satellite orbits at a height of 130 km, what minimum lens aperture (diameter) is required?
- *74. A Lucite planoconvex lens (Fig. 23-29a) has one flat surface and the other has $R = 18.4$ cm. This lens is used to view an object, located 66.0 cm away from the lens, which is a mixture of red and yellow. The index of refraction of the glass is 1.5106 for red light and 1.5226 for yellow light. What are the locations of the red and yellow images formed by the lens?

Answers to Exercises

An early science fantasy book (1940), called Mr Tompkins in Wonderland by physicist George Gamow, imagined a world in which the speed of light was only 10 m/s (20 mi/h). Mr Tompkins had studied relativity and when he began "speeding" on a bicycle, he "expected that he would be immediately shortened, and was very happy about it as his increasing figure had lately caused him some anxiety. To his great surprise, however, nothing happened to him or to his cycle. On the other hand, the picture around him completely changed. The streets grew shorter, the windows of the shops began to look like narrow slits, and the policeman on the corner became the thinnest man he had ever seen. 'By Jove!' exclaimed Mr Tompkins excitedly, 'I see the trick now. This is where the word relativity comes in.'"

Relativity does indeed predict that objects moving relative to us at high speed, close to the speed of light c , are shortened in length. We don't notice it as Mr Tompkins did, because $c = 3 \times 10^8 \text{ m/s}$ is incredibly fast. We will study length contraction, time dilation, simultaneity non-agreement, and how energy and mass are equivalent $(E = mc^2)$.

CHAPTER

The Special Theory of Relativity

hysics at the end of the nineteenth century looked back on a period of great progress. The theories developed over the preceding three centuries had been very successful in explaining a wide range of natural phenomena. Newtonian mechanics beautifully explained the motion of objects on Earth and in the heavens. Furthermore, it formed the basis for successful treatments of fluids, wave motion, and sound. Kinetic theory explained the behavior of gases and other materials. Maxwell's theory of electromagnetism not only brought together and explained electric and magnetic phenomena, but it predicted the existence of electromagnetic waves that would behave in every way just like light-so light came to be thought of as an electromagnetic wave. Indeed, it seemed that the natural world, as seen through the eves of physicists, was very well explained. A few puzzles remained, but it was felt that these would soon be explained using already known principles.

It did not turn out so simply. Instead, these puzzles were to be solved only by the introduction, in the early part of the twentieth century, of two revolutionary new theories that changed our whole conception of nature: the *theory of* relativity and quantum theory.

Physics as it was known at the end of the nineteenth century (what we've covered up to now in this book) is referred to as **classical physics**. The new physics that grew out of the great revolution at the turn of the twentieth century is now called **modern physics**. In this Chapter, we present the special theory of relativity, which was first proposed by Albert Einstein (1879–1955; Fig. 26–1) in 1905. In Chapter 27, we introduce the equally momentous quantum theory.

Classical vs. modern physics

FIGURE 26-1 Albert Einstein (1879–1955), one of the great minds of the twentieth century, was the creator of the special and general theories of relativity.

26-1 Galilean-Newtonian Relativity

Einstein's special theory of relativity deals with how we observe events, particularly how objects and events are observed from different frames of reference.[†] This subject had, of course, already been explored by Galileo and Newton.

The special theory of relativity deals with events that are observed and measured from so-called **inertial reference frames** which (as discussed in Chapter 4) are reference frames in which Newton's first law is valid: if an object experiences no net force, the object either remains at rest or continues in motion with constant speed in a straight line. It is easiest to analyze events when they are observed and measured from inertial frames. The Earth, though not quite an inertial frame (it rotates), is close enough that for most purposes we can consider it an inertial frame. Rotating or otherwise accelerating frames of reference are noninertial frames[†], and won't concern us in this Chapter (they are dealt with in Einstein's general theory of relativity—Section 33-4).

Inertial reference frame

A reference frame is a set of coordinate axes fixed to some body such as the Earth, a train, or the Moon. See Section 2-1.

[‡]On a rotating platform (say a merry-go-round), for example, an object at rest starts moving outward even though no body exerts a force on it. This is therefore not an inertial frame. See Appendix C, Fig. C-1.

Relativity principle: the laws of physics are the same in all inertial reference frames

A reference frame that moves with constant velocity with respect to an inertial frame is itself also an inertial frame, since Newton's laws hold in it as well. When we say that we observe or make measurements from a certain reference frame, it means that we are at rest in that reference frame.

Both Galileo and Newton were aware of what we now call the relativity principle applied to mechanics: that the basic laws of physics are the same in all *inertial reference frames*. You may have recognized its validity in everyday life. For example, objects move in the same way in a smoothly moving (constantvelocity) train or airplane as they do on Earth. (This assumes no vibrations or rocking which would make the reference frame noninertial.) When you walk, drink a cup of soup, play pool, or drop a pencil on the floor while traveling in a train, airplane, or ship moving at constant velocity, the bodies move just as they do when you are at rest on Earth. Suppose you are in a car traveling rapidly at constant velocity. If you release a coin from above your head inside the car, how will it fall? It falls straight downward with respect to the car, and hits the floor directly below the point of release, Fig. 26-2a. (If you drop the coin out the car's window, this won't happen because the moving air drags the coin backward relative to the car.) This is just how objects fall on the Earth—straight down—and thus our experiment in the moving car is in accord with the relativity principle.

FIGURE 26-2 A coin is dropped by a person in a moving car. The upper views show the moment of the coin's release, the lower views are a short time later. (a) In the reference frame of the car, the coin falls straight down (and the tree moves to the left). (b) In a reference frame fixed on the Earth, the coin follows a curved (parabolic) path.

Reference frame = Earth

Note in this example, however, that to an observer on the Earth, the coin follows a curved path, Fig. 26-2b. The actual path followed by the coin is different as viewed from different frames of reference. This does not violate the relativity principle because this principle states that the laws of physics are the same in all inertial frames. The same law of gravity, and the same laws of motion, apply in both reference frames. And the acceleration of the coin is the same in both reference frames. The difference in Figs. 26–2a and b is that in the Earth's frame of reference, the coin has an initial velocity (equal to that of the car). The laws of physics therefore predict it will follow a parabolic path like any projectile (Chapter 3). In the car's reference frame, there is no initial velocity, and the laws of physics predict that the coin will fall straight down. The laws are the same in both reference frames, although the specific paths are different.

Galilean-Newtonian relativity involves certain unprovable assumptions that make sense from everyday experience. It is assumed that the lengths of objects are the same in one reference frame as in another, and that time passes at the same rate in different reference frames. In classical mechanics, then, space and time intervals are considered to be **absolute**: their measurement does not change from one reference frame to another. The mass of an object, as well as all forces, are assumed to be unchanged by a change in inertial reference frame.

The position of an object, however, is different when specified in different reference frames, and so is velocity. For example, a person may walk inside a bus toward the front with a speed of 2 m/s . But if the bus moves 10 m/s with respect to the Earth, the person is then moving with a speed of 12 m/s with respect to the Earth. The acceleration of a body, however, is the same in any inertial reference frame according to classical mechanics. This is because the change in velocity, and the time interval, will be the same. For example, the person in the bus may accelerate from 0 to 2 m/s in 1.0 seconds, so $a = 2 \text{ m/s}^2$ in the reference frame of the bus. With respect to the Earth, the acceleration is

$$
\frac{(12 \text{ m/s} - 10 \text{ m/s})}{1.0 \text{ s}} = 2 \text{ m/s}^2,
$$

which is the same.

Since neither F , m , nor a changes from one inertial frame to another, then Newton's second law, $F = ma$, does not change. Thus Newton's second law satisfies the relativity principle. It is easily shown that the other laws of mechanics also satisfy the relativity principle.

That the laws of mechanics are the same in all inertial reference frames implies that no one inertial frame is special in any sense. We express this important conclusion by saying that all inertial reference frames are equivalent for the description of mechanical phenomena. No one inertial reference frame is any better than another. A reference frame fixed to a car or an aircraft traveling at constant velocity is as good as one fixed on the Earth. When you travel smoothly at constant velocity in a car or airplane, it is just as valid to say you are at rest and the Earth is moving as it is to say the reverse. There is no experiment you can do to tell which frame is "really" at rest and which is moving. Thus, there is no way to single out one particular reference frame as being at absolute rest.

A complication arose, however, in the last half of the nineteenth century. Maxwell's comprehensive and successful theory of electromagnetism (Chapter 22) predicted that light is an electromagnetic wave. Maxwell's equations gave the velocity of light c as 3.00×10^8 m/s; and this is just what is measured, within experimental error. The question then arose: in what reference frame does light have precisely the value predicted by Maxwell's theory? For it was assumed that light would have a different speed in different frames of reference. For example, if observers were traveling on a rocket ship at a speed of 1.0×10^8 m/s away from a source of light, we might expect them to measure the speed of the light reaching them to be

$$
(3.0 \times 10^8 \text{ m/s}) - (1.0 \times 10^8 \text{ m/s}) = 2.0 \times 10^8 \text{ m/s}.
$$

But Maxwell's equations have no provision for relative velocity. They predicted the speed of light to be $c = 3.0 \times 10^8$ m/s. This seemed to imply there must be some special reference frame where c would have this value.

CAUTION

Position and velocity are different in different reference frames, but length is the same (classical)

All inertial reference frames are equally valid The "ether"

We discussed in Chapters 11 and 12 that waves can travel on water and along ropes or strings, and sound waves travel in air and other materials. Nineteenth-century physicists viewed the material world in terms of the laws of mechanics, so it was natural for them to assume that light too must travel in some *medium*. They called this transparent medium the **ether** and assumed it permeated all space.[†] It was therefore assumed that the velocity of light given by Maxwell's equations must be with respect to the ether.

At first it appeared that Maxwell's equations did not satisfy the relativity principle. They were simplest in the frame where $c = 3.00 \times 10^8$ m/s; that is, in a reference frame at rest in the ether. In any other reference frame, extra terms would have to be added to take into account the relative velocity. Thus, although most of the laws of physics obeyed the relativity principle, the laws of electricity and magnetism apparently did not. (Einstein's second postulate see next Section—resolved this problem: Maxwell's equations do satisfy relativity.)

Scientists soon set out to determine the speed of the Earth relative to this absolute frame, whatever it might be. A number of clever experiments were designed. The most direct were performed by A. A. Michelson and E. W. Morley in the 1880s. They measured the difference in the speed of light in different directions using Michelson's interferometer (Section 24–9). They expected to find a difference depending on the orientation of their apparatus with respect to the ether. For just as a boat has different speeds relative to the land when it moves upstream, downstream, or across the stream, so too light would be expected to have different speeds depending on the velocity of the ether past the Earth.

Strange as it may seem, they detected no difference at all. This was a great puzzle. A number of explanations were put forth over a period of years, but they led to contradictions or were otherwise not generally accepted. This null result was one of the great puzzles at the end of the nineteenth century.

The null result

The Michelson-Morley experiment

Then in 1905, Albert Einstein proposed a radical new theory that reconciled these many problems in a simple way. But at the same time, as we shall see, it completely changed our ideas of space and time.

26-2 Postulates of the **Special Theory of Relativity**

The problems that existed at the start of the twentieth century with regard to electromagnetic theory and Newtonian mechanics were beautifully resolved by Einstein's introduction of the theory of relativity in 1905. Unaware of the Michelson-Morley null result, Einstein was motivated by certain questions regarding electromagnetic theory and light waves. For example, he asked himself: "What would I see if I rode a light beam?" The answer was that instead of a traveling electromagnetic wave, he would see alternating electric and magnetic fields at rest whose magnitude changed in space, but did not change in time. Such fields, he realized, had never been detected and indeed were not consistent with Maxwell's electromagnetic theory. He argued, therefore, that it was unreasonable to think that the speed of light relative to any observer could be reduced to zero, or in fact reduced at all. This idea became the second postulate of his theory of relativity.

[†]The medium for light waves could not be air, since light travels from the Sun to Earth through nearly empty space. Therefore, another medium was postulated, the ether. The ether was not only transparent but, because of difficulty in detecting it, was assumed to have zero density.
In his famous 1905 paper, Einstein proposed doing away completely with the idea of the ether and the accompanying assumption of an absolute reference frame at rest. This proposal was embodied in two postulates. The first postulate was an extension of the Galilean–Newtonian relativity principle to include not only the laws of mechanics but also those of the rest of physics, including electricity and magnetism:

First postulate[†] (*the relativity principle*): The laws of physics have the same form in all inertial reference frames.

The second postulate is consistent with the first:

Second postulate (constancy of the speed of light): Light propagates through empty space with a definite speed c independent of the speed of the source or observer.

These two postulates form the foundation of Einstein's special theory of relativity. It is called "special" to distinguish it from his later "general theory of relativity," which deals with noninertial (accelerating) reference frames (Chapter 33). The special theory, which is what we discuss here, deals only with inertial frames.

The second postulate may seem hard to accept, for it seems to violate common sense. First of all, we have to think of light traveling through empty space. Giving up the ether is not too hard, however, since it had never been detected. But the second postulate also tells us that the speed of light in vacuum is always the same, 3.00×10^8 m/s, no matter what the speed of the observer or the source. Thus, a person traveling toward or away from a source of light will measure the same speed for that light as someone at rest with respect to the source. This conflicts with our everyday experience: we would expect to have to add in the velocity of the observer. On the other hand, perhaps we can't expect our everyday experience to be helpful when dealing with the high velocity of light. Furthermore, the null result of the Michelson–Morley experiment is fully consistent with the second postulate. $\frac{1}{x}$

Einstein's proposal has a certain beauty. By doing away with the idea of an absolute reference frame, it was possible to reconcile classical mechanics with Maxwell's electromagnetic theory. The speed of light predicted by Maxwell's equations is the speed of light in vacuum in *any* reference frame.

Einstein's theory required us to give up commonsense notions of space and time, and in the following Sections we will examine some strange but interesting consequences of special relativity. Our arguments for the most part will be simple ones. We will use a technique that Einstein himself did: we will imagine very simple experimental situations in which little mathematics is needed. In this way, we can see many of the consequences of relativity theory without getting involved in detailed calculations. Einstein called these "thought" experiments.

26-3 Simultaneity

An important consequence of the theory of relativity is that we can no longer regard time as an absolute quantity. No one doubts that time flows onward and never turns back. But the time interval between two events, and even whether or not two events are simultaneous, depends on the observer's reference frame. By an "event," which we use a lot here, we mean something that happens at a particular place and at a particular time.

[†]The first postulate can also be stated as: There is no experiment you can do in an inertial reference frame to tell if you are at rest or moving uniformly at constant velocity.

[‡]The Michelson–Morley experiment can also be considered as evidence for the first postulate, since it was intended to measure the motion of the Earth relative to an absolute reference frame. Its failure to do so implies the absence of any such preferred frame.

The first *postulate of* special relativity

The second postulate of special relativity

"Thought experiment"

Event defined

Two events are said to occur simultaneously if they occur at exactly the same time. But how do we know if two events occur precisely at the same time? If they occur at the same point in space—such as two apples falling on your head at the same time—it is easy. But if the two events occur at widely separated places, it is more difficult to know whether the events are simultaneous since we have to take into account the time it takes for the light from them to reach us. Because light travels at finite speed, a person who sees two events must calculate back to find out when they actually occurred. For example, if two events are *observed* to occur at the same time, but one actually took place farther from the observer than the other, then the more distant one must have occurred earlier, and the two events were not simultaneous.

We now imagine a simple thought experiment. Assume an observer, called O, is located exactly halfway between points A and B where two events occur, Fig. 26–3. Suppose the two events are lightning that strikes the points A and B, as shown. For brief events like lightning, only short pulses of light will travel outward from A and B and reach O. Observer O "sees" the events when the pulses of light reach point O. If the two pulses reach O at the same time, then the two events had to be simultaneous. This is because the two light pulses travel at the same speed (postulate 2), and since the distance OA equals OB, the time for the light to travel from A to O and B to O must be the same. Observer O can then definitely state that the two events occurred simultaneously. On the other hand, if O sees the light from one event before that from the other, then the former event occurred first.

FIGURE 26-3 A moment after lightning strikes at points A and B, the pulses of light are traveling toward the observer O, but O "sees" the lightning only when the light reaches O.

> The question we really want to examine is this: if two events are simultaneous to an observer in one reference frame, are they also simultaneous to another observer moving with respect to the first? Let us call the observers O_1 and O_2 and assume they are fixed in reference frames 1 and 2 that move with speed v relative to one another. These two reference frames can be thought of as trains (Fig. 26–4). O_2 says that O_1 is moving to the right with speed v, as in Fig. 26–4a; and O₁ says O₂ is moving to the left with speed v, as in Fig. 26–4b. Both viewpoints are legitimate according to the relativity principle. There is no third point of view which will tell us which one is "really" moving.

FIGURE 26-4 Observers O_1 and $O₂$, on two different trains (two different reference frames), are moving with relative speed v . O_2 says that O_1 is moving to the right (a); O_1 says that O_2 is moving to the left (b). Both viewpoints are legitimate-it all depends on your reference frame.

FIGURE 26-5 Thought experiment on simultaneity. To observer O_2 , the reference frame of O_1 is moving to the right. In (a), one lightning bolt strikes the two reference frames at A_1 and A_2 , and a second lightning bolt strikes at B_1 and B_2 . (b) A moment later, the light from the two events reaches $O₂$ at the same time, so according to observer O_2 , the two bolts of lightning strike simultaneously. But in O_1 's reference frame, the light from B_1 has already reached $O₁$, whereas the light from A_1 has not yet reached O_1 . So in O_1 's reference frame, the event at B_1 must have preceded the event at A_1 . Simultaneity in time is not absolute.

Now suppose that observers O_1 and O_2 observe and measure two lightning strikes. The lightning bolts mark both trains where they strike: at A_1 and B_1 on O_1 's train, and at A_2 and B_2 on O_2 's train, Fig. 26–5a. For simplicity, we assume that O_1 is exactly halfway between A_1 and B_1 , and that O_2 is halfway between A_2 and B_2 . Let us first put ourselves in O_2 's reference frame, so we observe O_1 moving to the right with speed v. Let us also assume that the two events occur simultaneously in O_2 's frame, and just at the instant when O_1 and O_2 are opposite each other, Fig. 26–5a. A short time later, Fig. 26–5b, the light from A_2 and B_2 reaches O_2 at the same time (we assumed this). Since O_2 knows (or measures) the distances O_2A_2 and O_2B_2 as equal, O_2 knows the two events are simultaneous in the O_2 reference frame.

But what does observer O_1 observe and measure? From our (O_2) reference frame, we can predict what O_1 will observe. We see that O_1 moves to the right during the time the light is traveling to O_1 from A_1 and B_1 . As shown in Fig. 26–5b, we can see from our O_2 reference frame that the light from B_1 has already passed O_1 , whereas the light from A_1 has not yet reached O_1 . That is, O_1 observes the light coming from B_1 before observing the light coming from A_1 . Given (1) that light travels at the same speed c in any direction and in any reference frame, and (2) that the distance O_1A_1 equals O_1B_1 , then observer O_1 can only conclude that the event at B_1 occurred before the event at A_1 . The two events are not simultaneous for O_1 , even though they are for O_2 .

We thus find that two events which take place at different locations and are simultaneous to one observer, are actually not simultaneous to a second observer who moves relative to the first.

It may be tempting to ask: "Which observer is right, O_1 or O_2 ?" The answer, according to relativity, is that they are both right. There is no "best" reference frame we can choose to determine which observer is right. Both frames are equally good. We can only conclude that *simultaneity is not an absolute concept*, but is relative. We are not aware of it in everyday life, however, because the effect is noticeable only when the relative speed of the two reference frames is very large (near c), or the distances involved are very large.

EXERCISE A Examine the experiment of Fig. 26-5 from O₁'s reference frame. In this case, O_1 will be at rest and will see event B_1 occur before A_1 . Will O_1 recognize that $O₂$, who is moving with speed v to the left, will see the two events as simultaneous? (*Hint*: draw a diagram equivalent to Fig. 26-5.)

Simultaneity *is relative*

26-4 Time Dilation and the Twin Paradox

The fact that two events simultaneous to one observer may not be simultaneous to a second observer suggests that time itself is not absolute. Could it be that time passes differently in one reference frame than in another? This is, indeed, just what Einstein's theory of relativity predicts, as the following thought experiment shows.

Figure 26-6 shows a spaceship traveling past Earth at high speed. The point of view of an observer on the spaceship is shown in part (a), and that of an observer on Earth in part (b). Both observers have accurate clocks. The person on the spaceship (a) flashes a light and measures the time it takes the light to travel across the spaceship and return after reflecting from a mirror. In the reference frame of the spaceship, the light travels a distance 2D at speed c ; so the time required to go across and back, which we call Δt_0 , is

Time interval measured by observer on spaceship

FIGURE 26-6 Time dilation can be shown by a thought experiment: the time it takes for light to travel across a spaceship and back is longer for the

observer on Earth (b) than for the

observer on the spaceship (a).

$$
\Delta t_0 = \frac{2D}{c} \cdot
$$

The observer on Earth, Fig. 26-6b, observes the same process. But to this observer, the spaceship is moving. So the light travels the diagonal path shown going across the spaceship, reflecting off the mirror, and returning to the sender. Although the light travels at the same speed to this observer (the second postulate), it travels a greater distance. Hence the time required, as measured by the observer on Earth, will be *greater* than that measured by the observer on the spaceship.

The time interval, Δt , observed by the observer on Earth can be calculated as follows. In the time Δt , the spaceship travels a distance $2L = v \Delta t$ where v is the speed of the spaceship (Fig. 26–6b). Thus, the light travels a total distance on its diagonal path (Pythagorean theorem) of $2\sqrt{D^2 + L^2}$, where $L = v \Delta t/2$, and therefore

$$
c = \frac{2\sqrt{D^2 + L^2}}{\Delta t} = \frac{2\sqrt{D^2 + v^2(\Delta t)^2/4}}{\Delta t}
$$

We square both sides,

$$
c^2 = \frac{4D^2}{(\Delta t)^2} + v^2,
$$

and solve for Δt , to find

$$
(\Delta t)^2 = \frac{4D^2}{c^2 - v^2}
$$

$$
\Delta t = \frac{2D}{c\sqrt{1 - v^2/c^2}}.
$$

 \sim \sim 2

We combine this equation with the formula on page 734, $\Delta t_0 = 2D/c$.

$$
\Delta t = \frac{\Delta t_0}{\sqrt{1 - v^2/c^2}}.
$$

Since $\sqrt{1 - v^2/c^2}$ is always less than 1, we see that $\Delta t > \Delta t_0$. That is, the time interval between the two events (the sending of the light, and its reception on the spaceship) is *greater* for the observer on Earth than for the observer on the spaceship. This is a general result of the theory of relativity, and is known as time dilation. Stated simply, the time dilation effect says that

clocks moving relative to an observer are measured by that observer to run more slowly (as compared to clocks at rest).

However, we should not think that the clocks are somehow at fault. Time is actually measured to pass more slowly in any moving reference frame as compared to your own. This remarkable result is an inevitable outcome of the two postulates of the theory of relativity.

The factor $1/\sqrt{1-v^2/c^2}$ occurs so often in relativity that we often give it the shorthand symbol γ , and write Eq. 26–1a as

$$
t = \gamma \Delta t_0 \tag{26-1b}
$$

where

Δ

$$
\gamma = \frac{1}{\sqrt{1 - v^2/c^2}}.
$$
 (26-2)

Note that γ is never less than one. At normal speeds, $\gamma = 1$ to a few decimal places; in general, $\gamma \geq 1$.

The concept of time dilation may be hard to accept, for it contradicts our experience. We can see from Eq. 26-1 that the time dilation effect is indeed negligible unless v is reasonably close to c. If v is much less than c, then the term v^2/c^2 is much smaller than the 1 in the denominator of Eq. 26–1a, and then $\Delta t \approx \Delta t_0$ (see Example 26–2). The speeds we experience in everyday life are much smaller than c , so it is little wonder we don't ordinarily notice time dilation. Experiments have tested the time dilation effect, and have confirmed Einstein's predictions. In 1971, for example, extremely precise atomic clocks were flown around the world in jet planes. The speed of the planes (10^3 km/h) was much less than c, so the clocks had to be accurate to nanoseconds $(10^{-9} s)$ in order to detect any time dilation. They were this accurate, and they confirmed Eq. 26–1 to within experimental error. Time dilation had been confirmed decades earlier, however, by observation on "elementary particles" which have very small masses (typically 10^{-30} to 10^{-27} kg) and so require little energy to be accelerated to speeds close to the speed of light, c. Many of these elementary particles are not stable and decay after a time into lighter particles. One example is the muon, whose mean lifetime is 2.2 μ s when at rest. Careful experiments showed that when a muon is traveling at high speeds, its lifetime is measured to be longer than when it is at rest, just as predicted by the time dilation formula.

 $(26-1a)$ Time dilation formula

> Time dilation: moving clocks run slow

Time dilation

 γ defined

Why we don't usually notice time dilation

Experimental confirmation

EXAMPLE 26-1 Lifetime of a moving muon. (a) What will be the mean lifetime of a muon as measured in the laboratory if it is traveling at $v = 0.60c = 1.80 \times 10^8$ m/s with respect to the laboratory? Its mean lifetime at rest is 2.20 μ s = 2.20 \times 10⁻⁶ s. (b) How far does a muon travel in the laboratory, on average, before decaying?

APPROACH If an observer were to move along with the muon (the muon would be at rest to this observer), the muon would have a mean life of 2.2×10^{-6} s. To an observer in the lab, the muon lives longer because of time dilation. We find the mean lifetime using Eq. 26–1a and the average distance from $d = v \Delta t$.

SOLUTION (a) From Eq. 26–1a with $v = 0.60c$, we have

$$
\Delta t = \frac{\Delta t_0}{\sqrt{1 - \frac{v^2}{c^2}}} = \frac{2.20 \times 10^{-6} \text{ s}}{\sqrt{1 - \frac{0.36c^2}{c^2}}} = \frac{2.20 \times 10^{-6} \text{ s}}{\sqrt{0.64}} = 2.8 \times 10^{-6} \text{ s}.
$$

(b) Relativity predicts that a muon would travel an average distance $d = v \Delta t = (0.60)(3.0 \times 10^8 \text{ m/s})(2.8 \times 10^{-6} \text{ s}) = 500 \text{ m}$, and this is the distance that is measured experimentally in the laboratory.

NOTE At a speed of 1.8×10^8 m/s, classical physics would tell us that with a mean life of $2.2 \mu s$, an average muon would travel $d = vt = (1.8 \times 10^8 \text{ m/s})(2.2 \times 10^{-6} \text{ s}) = 400 \text{ m}$. This is shorter than the distance measured.

EXERCISE B What is the muon's mean life in Example 26-1 if v is (a) $0.10c$, (b) $0.90c$?

We need to clarify how to use Eq. 26–1, and the meaning of Δt and Δt_0 . The equation is true only when Δt_0 represents the time interval between the two events in a reference frame where the two events occur at the same point in space (as in Fig. 26–6a where the two events are the light flash being sent and being received). This time interval, Δt_0 , is called the **proper time**. Then Δt in Eq. 26–1 represents the time interval between the two events as measured in a reference frame moving with speed v with respect to the first. In Example 26–1 above, Δt_0 (and not Δt) was set equal to 2.2 \times 10⁻⁶ s because it is only in the rest frame of the muon that the two events ("birth" and "decay") occur at the same point in space. The proper time Δt_0 is the shortest time between the events any observer can measure. In any other moving reference frame, the time Δt is greater.

EXAMPLE 26-2 Time dilation at 100 km/h. Let's check time dilation for everyday speeds. A car traveling 100 km/h covers a certain distance in 10.00 s according to the driver's watch. What does an observer at rest on Earth measure for the time interval?

APPROACH The car's speed relative to Earth is $100 \text{ km/h} =$ $(1.00 \times 10^5 \text{ m})/(3600 \text{ s}) = 27.8 \text{ m/s}$. The driver is at rest in the reference frame of the car, so we set $\Delta t_0 = 10.00$ s in the time dilation formula. **SOLUTION** We use Eq. 26-1a:

$$
\Delta t = \frac{\Delta t_0}{\sqrt{1 - \frac{v^2}{c^2}}} = \frac{10.00 \text{ s}}{\sqrt{1 - \left(\frac{27.8 \text{ m/s}}{3.00 \times 10^8 \text{ m/s}}\right)^2}} = \frac{10.00 \text{ s}}{\sqrt{1 - (8.59 \times 10^{-15})}}.
$$

If you put these numbers into a calculator, you will obtain $\Delta t = 10.00$ s, since the denominator differs from 1 by such a tiny amount. Indeed, the time measured by an observer on Earth would show no difference from that measured by the driver, even with the best instruments. A computer that could calculate to a large number of decimal places would show Δt is greater than Δt_0 by about 4×10^{-14} s.

The proper time Δt_0 is in a reference frame where the two events occur at the same point in space **NOTE** We can estimate the difference using the binomial expansion (Appendix A),

PROBLEM SOLVING Use of the binomial expansion

$$
(1 \pm x)^n \approx 1 \pm nx.
$$
 [for $x \ll 1$]

In our time dilation formula, we have the factor $\gamma = (1 - v^2/c^2)^{-\frac{1}{2}}$. Thus

$$
\Delta t = \gamma \Delta t_0
$$

= $\Delta t_0 \left(1 - \frac{v^2}{c^2} \right)^{-\frac{1}{2}}$

$$
\approx \Delta t_0 \left(1 + \frac{1}{2} \frac{v^2}{c^2} \right)
$$

$$
\approx 10.00 \text{ s} \left[1 + \frac{1}{2} \left(\frac{27.8 \text{ m/s}}{3.00 \times 10^8 \text{ m/s}} \right)^2 \right]
$$

$$
\approx 10.00 \text{ s} + 4 \times 10^{-14} \text{ s}.
$$

So the difference between Δt and Δt_0 is predicted to be 4×10^{-14} s, an extremely small amount.

EXERCISE C A certain atomic clock keeps perfect time on Earth. If the clock is taken on a spaceship traveling at a speed $v = 0.60c$, does this clock now run slow according to the people (a) on the spaceship, (b) on Earth?

Space Travel?

Time dilation has aroused interesting speculation about space travel. According to classical (Newtonian) physics, to reach a star 100 light-years away would not be possible for ordinary mortals (1 light-year is the distance light can travel in 1 year = 3.0×10^8 m/s $\times 3.16 \times 10^7$ s = 9.5×10^{15} m). Even if a spaceship could travel at close to the speed of light, it would take over 100 years to reach such a star. But time dilation tells us that the time involved would be less for an astronaut. In a spaceship traveling at $v = 0.999c$, the time for such a trip would be only about

$$
\Delta t_0 = \Delta t \sqrt{1 - v^2/c^2}
$$

= (100 yr) $\sqrt{1 - (0.999)^2}$
= 4.5 yr.

Thus time dilation allows such a trip, but the enormous practical problems of achieving such speeds may not be possible to overcome, certainly not in the near future.

In this example, 100 years would pass on Earth, whereas only 4.5 years would pass for the astronaut on the trip. Is it just the clocks that would slow down for the astronaut? No. All processes, including aging and other life processes, run more slowly for the astronaut according to the Earth observer. But to the astronaut, time would pass in a normal way. The astronaut would experience 4.5 years of normal sleeping, eating, reading, and so on. And people on Earth would experience 100 years of ordinary activity.

Twin Paradox

Twin paradox

Not long after Einstein proposed the special theory of relativity, an apparent paradox was pointed out. According to this twin paradox, suppose one of a pair of 20-year-old twins takes off in a spaceship traveling at very high speed to a distant star and back again, while the other twin remains on Earth. According to the Earth twin, the astronaut twin will age less. Whereas 20 years might pass for the Earth twin, perhaps only 1 year (depending on the spacecraft's speed) would pass for the traveler. Thus, when the traveler returns, the earthbound twin could expect to be 40 years old whereas the traveling twin would be only 21.

This is the viewpoint of the twin on the Earth. But what about the traveling twin? If all inertial reference frames are equally good, won't the traveling twin make all the claims the Earth twin does, only in reverse? Can't the astronaut twin claim that since the Earth is moving away at high speed, time passes more slowly on Earth and the twin on Earth will age less? This is the opposite of what the Earth twin predicts. They cannot both be right, for after all the spacecraft returns to Earth and a direct comparison of ages and clocks can be made.

There is, however, no contradiction here. The consequences of the special theory of relativity—in this case, time dilation—can be applied only by observers in an inertial reference frame. The Earth is such a frame (or nearly so), whereas the spacecraft is not. The spacecraft accelerates at the start and end of its trip and when it turns around at the far point of its journey. During the acceleration, the twin on the spacecraft is not in an inertial frame. In between, the astronaut twin may be in an inertial frame (and is justified in saying the Earth twin's clocks run slow), but it is not always the same frame. So she cannot predict their relative ages when she returns to Earth. The Earth twin stays in the same inertial frame, and we can thus trust her predictions based on special relativity. Thus, there is no paradox. The prediction of the Earth twin that the traveling twin ages less is the proper one.

$*$ Additional Example—Using γ

EXAMPLE 26-3 γ for various speeds. Determine the value of γ for a speed v equal to (a) $0, (b)$ 0.010c, (c) 0.10c, (d) 0.50c, (e) 0.90c, (f) 0.990c.

APPROACH We simply plug into Eq. $26-2$.

SOLUTION (*a*) For $v = 0, \gamma = 1/1 = 1$ exactly. (b) For $v = 0.010c = 3.0 \times 10^6 \text{ m/s}$ (a pretty high speed):

$$
\gamma = \frac{1}{\sqrt{1 - \left(\frac{0.010c}{c}\right)^2}}
$$

$$
= \frac{1}{\sqrt{1 - (0.010)^2}} = \frac{1}{\sqrt{0.99990}} = 1.00005.
$$

Unless v is given to more significant figures, $\gamma = 1.0$ here. We see that γ is never less than 1.0 and will only exceed 1.0 significantly at higher speeds.

(c) For a speed 10 times higher, $v = 0.10c$, we get

$$
\gamma = \frac{1}{\sqrt{1 - (0.10)^2}} = \frac{1}{\sqrt{0.99}} = 1.005.
$$

 (d) At a speed half the speed of light

$$
\gamma = \frac{1}{\sqrt{1 - (0.50)^2}} = 1.15.
$$

(e) At $v = 0.90c$ we get $\gamma = 2.3$.

(*f*) At $v = 0.990c$ we get $\gamma = 7.1$.

Table 26–1 is a handy summary of these results.

Global Positioning System (GPS)

Airplanes, cars, boats, and hikers use global positioning system (GPS) receivers to tell them quite accurately where they are, at a given moment. The 24 global positioning system satellites send out precise time signals using atomic clocks. Your receiver compares the times received from at least four satellites, all of whose times are carefully synchronized to within 1 part in 10^{13} . By comparing the time differences with the known satellite positions and the fixed speed of light, the receiver can determine how far it is from each satellite and thus where it is on the Earth. It can do this to a typical accuracy of 15 m, if it has been constructed to make corrections such as the one below due to special relativity.

CONCEPTUAL EXAMPLE 26-4 A relativity correction to GPS. GPS satellites move at about $4 \text{ km/s} = 4000 \text{ m/s}$. Show that a good GPS receiver needs to correct for time dilation if it is to produce results consistent with atomic clocks accurate to 1 part in 10^{13} .

RESPONSE Let us calculate the magnitude of the time dilation effect by inserting $v = 4000 \text{ m/s}$ into Eq. 26-1a:

$$
\Delta t = \frac{1}{\sqrt{1 - \frac{v^2}{c^2}}} \Delta t_0
$$

=
$$
\frac{1}{\sqrt{1 - (\frac{4 \times 10^3 \text{ m/s}}{3 \times 10^8 \text{ m/s}})^2}} \Delta t_0
$$

=
$$
\frac{1}{\sqrt{1 - 1.8 \times 10^{-10}}} \Delta t_0.
$$

We use the binomial expansion: $(1 \pm x)^n \approx 1 \pm nx$ for $x \ll 1$ (see Appendix A) which here is $(1 - x)^{-\frac{1}{2}} \approx 1 + \frac{1}{2}x$. That is

$$
\Delta t = \left(1 + \frac{1}{2}(1.8 \times 10^{-10})\right) \Delta t_0 = \left(1 + 9 \times 10^{-11}\right) \Delta t_0.
$$

The time "error" divided by the time interval is

$$
\frac{(\Delta t - \Delta t_0)}{\Delta t_0} = 1 + 9 \times 10^{-11} - 1 = 9 \times 10^{-11} \approx 1 \times 10^{-10}
$$

Time dilation, if not accounted for, would introduce an error of about 1 part in 10^{10} , which is 1000 times greater than the precision of the atomic clocks. Not correcting for time dilation means a receiver could give much poorer position accuracy.

NOTE GPS devices must make other corrections as well, including effects associated with General Relativity.

 \overrightarrow{A} PHYSICS APPLIED Global positioning system (GPS)

FIGURE 26-7 (a) A spaceship traveling at very high speed from Earth to the planet Neptune, as seen from Earth's frame of reference. (b) According to an observer on the spaceship, Earth and Neptune are moving at the very high speed v: Earth leaves the spaceship, and a time Δt_0 later Neptune arrives at the spaceship.

5 Length Contraction

Not only time intervals are different in different reference frames. Space intervals—lengths and distances—are different as well, according to the special theory of relativity, and we illustrate this with a thought experiment.

Observers on Earth watch a spacecraft traveling at speed v from Earth to, say, Neptune, Fig. 26–7a. The distance between the planets, as measured by the Earth observers, is L_0 . The time required for the trip, measured from Earth, is

$$
\Delta t = \frac{L_0}{v}.
$$
 [Earth observer]

In Fig. 26–7b we see the point of view of observers on the spacecraft. In this frame of reference, the spaceship is at rest; Earth and Neptune move[†] with speed v. The time between departure of Earth and arrival of Neptune (observed from the spacecraft) is the "proper time," since the two events occur at the same point in space (i.e., on the spacecraft). Therefore the time interval is less for the spacecraft observers than for the Earth observers. That is, because of time dilation (Eq. 26–1), the time for the trip as viewed by the spacecraft is

$$
\Delta t_0 = \Delta t \sqrt{1 - v^2/c^2}
$$
 [spacecraft observer]
= $\Delta t/\gamma$.

Because the spacecraft observers measure the same speed but less time between these two events, they also measure the distance as less. If we let L be the distance between the planets as viewed by the spacecraft observers, then $L = v \Delta t_0$, which we can rewrite as $L = v \Delta t_0 = v \Delta t \sqrt{1 - v^2/c^2} = L_0 \sqrt{1 - v^2/c^2}$. Thus we have the important result that

$$
L = L_0 \sqrt{1 - v^2/c^2} \tag{26-3a}
$$

or, using γ (Eq. 26-2),

$$
L = \frac{L_0}{\gamma}.
$$
 (26–3b)

This is a general result of the special theory of relativity and applies to lengths of objects as well as to distance between objects. The result can be stated most simply in words as:

Length contraction: moving objects are shorter

the length of an object is measured to be shorter when it is moving relative to the observer than when it is at rest.

(in the direction of motion) \triangleright CAUTION

Proper length is measured in reference frame where the two positions are at rest This is called length contraction. The length L_0 in Eq. 26–3 is called the proper length. It is the length of the object (or distance between two points whose positions are measured at the same time) as determined by *observers at rest* with respect to it. Equation $26-3$ gives the length L that will be measured by observers when the object travels past them at speed v .

[†]We assume v is much greater than the relative speed of Neptune and Earth, so the latter can be ignored.

Length contraction formula

It is important to note that length contraction occurs only along the direction of motion. For example, the moving spaceship in Fig. 26–7a is shortened in length, but its height is the same as when it is at rest.

Length contraction, like time dilation, is not noticeable in everyday life because the factor $\sqrt{1-v^2/c^2}$ in Eq. 26–3 differs from 1.00 significantly only when v is very large.

EXAMPLE 26-5 Painting's contraction. A rectangular painting measures 1.00 m tall and 1.50 m wide. It is hung on the side wall of a spaceship which is moving past the Earth at a speed of 0.90c. See Fig. $26-8a$. (a) What are the dimensions of the picture according to the captain of the spaceship? (b) What are the dimensions as seen by an observer on the Earth?

APPROACH We apply the length contraction formula, Eq. 26–3, to the dimension parallel to the motion; v is the speed of the painting relative to the observer.

SOLUTION (a) The painting is at rest ($v = 0$) on the spaceship so it (as well as everything else in the spaceship) looks perfectly normal to everyone on the spaceship. The captain sees a 1.00-m by 1.50-m painting.

 (b) Only the dimension in the direction of motion is shortened, so the height is unchanged at 1.00 m, Fig. 26-8b. The length, however, is contracted to

$$
L = L_0 \sqrt{1 - \frac{v^2}{c^2}}
$$

= (1.50 m) $\sqrt{1 - (0.90)^2}$ = 0.65 m.

So the picture has dimensions $1.00 \text{ m} \times 0.65 \text{ m}$.

EXAMPLE 26-6 A fantasy supertrain. A very fast train with a proper length of 500 m is passing through a 200-m-long tunnel. The train's speed is so great that the train fits completely within the tunnel as seen by an observer at rest on the Earth (on the mountain above the tunnel); that is, the engine is just about to emerge from one end of the tunnel as the last car disappears into the other end. What is the train's speed?

APPROACH Since the train just fits inside the tunnel, its length measured by the person on the ground is 200 m . The length contraction formula, Eq. $26-3$, can thus be used to solve for v .

SOLUTION Substituting $L = 200$ m and $L_0 = 500$ m into Eq. 26–3 gives

$$
200 \text{ m} = 500 \text{ m} \sqrt{1 - \frac{v^2}{c^2}};
$$

dividing both sides by 500 m and squaring, we get

$$
(0.40)^2 = 1 - \frac{v^2}{c^2}
$$

or

$$
\frac{v}{c} = \sqrt{1 - (0.40)^2}
$$

$$
v = 0.92c.
$$

NOTE No real train could go this fast. But it is fun to think about.

NOTE An observer on the *train* would *not* see the two ends of the train inside the tunnel at the same time; simultaneity is relative.

EXERCISE D At what spaceship speed would the painting of Example 26–5 look contracted by only 10 cm (to $L = 1.40$ m) according to Earth observers?

 (b)

 (a)

FIGURE $26-8$ Example $26-5$.

FIGURE 26-9 According to an accurate clock on a fast-moving train, a person (a) begins dinner at 7:00 and (b) finishes at $7:15$. At the beginning of the meal, observers on Earth set their watches to correspond with the clock on the train. These observers measure the eating time as 20 minutes.

26-6 Four-Dimensional Space-Time

Let us imagine a person is on a train moving at a very high speed, say 0.65c, Fig. 26–9. This person begins a meal at 7:00 and finishes at 7:15, according to a clock on the train. The two events, beginning and ending the meal, take place at the same point on the train. So the proper time between these two events is 15 min. To observers on Earth, the meal will take longer—20 min according to Eq. $26-1$. Let us assume that the meal was served on a 20 -cm-diameter plate. To observers on the Earth, the plate is only 15 cm wide (length contraction). Thus, to observers on the Earth, the meal looks smaller but lasts longer.

In a sense the two effects, time dilation and length contraction, balance each other. When viewed from the Earth, what an object seems to lose in size it gains in length of time it lasts. Space, or length, is exchanged for time.

Considerations like this led to the idea of four-dimensional space-time: space takes up three dimensions and time is a fourth dimension. Space and time are intimately connected. Just as when we squeeze a balloon we make one dimension larger and another smaller, so when we examine objects and events from different reference frames, a certain amount of space is exchanged for time, or vice versa.

Although the idea of four dimensions may seem strange, it refers to the idea that any object or event is specified by four quantities—three to describe where in space, and one to describe when in time. The really unusual aspect of four-dimensional space-time is that space and time can intermix: a little of one can be exchanged for a little of the other when the reference frame is changed.

It is difficult for most of us to understand the idea of four-dimensional space-time. Somehow we feel, just as physicists did before the advent of relativity, that space and time are completely separate entities. Yet we have found in our thought experiments that they are not completely separate. And think about Galileo and Newton. Before Galileo, the vertical direction, that in which objects fall, was considered to be distinctly different from the two horizontal dimensions. Galileo showed that the vertical dimension differs only in that it happens to be the direction in which gravity acts. Otherwise, all three dimensions are equivalent, a viewpoint we all accept today. Now we are asked to accept one more dimension, time, which we had previously thought of as being somehow different. This is not to say that there is no distinction between space and time. What relativity has shown is that space and time determinations are not independent of one another.

Relativistic Momentum and Mass

So far in this Chapter, we have seen that two basic mechanical quantities, length and time intervals, need modification because they are relative—their value depends on the reference frame from which they are measured. We might expect that other physical quantities might need some modification according to the theory of relativity, such as momentum, energy, and mass.

The analysis of collisions between two particles shows that if we want to preserve the law of conservation of momentum in relativity, we must redefine momentum as

Relativistic momentum

$$
p = \frac{m_0 v}{\sqrt{1 - v^2/c^2}} = \gamma m_0 v.
$$
 (26-4)

Here γ is shorthand for $1/\sqrt{1-v^2/c^2}$ as before (Eq. 26–2). For speeds

much less than the speed of light, Eq. 26-4 gives the classical momentum, $p = m_0 v$.

We have written m_0 rather than m because Eq. 26-4 suggests to some physicists a relativistic interpretation of mass. Namely, that an object at rest has a rest mass m_0 , but that its mass can increase with speed according to the formula

$$
m_{\rm rel} = \frac{m_0}{\sqrt{1 - v^2/c^2}} = \gamma m_0,
$$

Mass increase formula

 $(26-5)$

where m_{rel} is called the **relativistic mass**. But be careful *not* to think a mass acquires more particles or more molecules as its speed becomes very large. It doesn't. In fact, many physicists believe an object has only one mass (its rest mass), and that it is only the momentum that increases with speed, a relativistic effect that everyone agrees to. [We use subscripts on m (m_0 and m_{rel}) to avoid any misunderstanding. If you see m without a subscript, you can feel pretty confident that it means rest mass.]

Relativistic momentum has been tested many times on tiny elementary particles (such as muons), and it has been found to increase in accord with Eq. 26-4.

EXAMPLE 26-7 Momentum of moving electron. Compare the momentum of an electron when it has a speed of (a) 4.00×10^7 m/s in the CRT of a television set, and (b) 0.98 c in an accelerator used for cancer therapy.

APPROACH We use Eq. 26-4 for the momentum of a moving electron. **SOLUTION** (a) At $v = 4.00 \times 10^7$ m/s, the electron's momentum is

$$
p = \frac{m_0 v}{\sqrt{1 - \frac{v^2}{c^2}}} = \frac{m_0 v}{\sqrt{1 - \frac{(4.00 \times 10^7 \text{ m/s})^2}{(3.00 \times 10^8 \text{ m/s})^2}}} = 1.01 m_0 v.
$$

The factor $\gamma = 1/\sqrt{1 - v^2/c^2} \approx 1.01$, so the momentum is only about 1% greater than the classical value. (If we put in the rest mass of an electron, $m_0 = 9.11 \times 10^{-31}$ kg, the momentum is $p = 1.01 m_0 v = 3.68 \times 10^{-23}$ kg·m/s.) (b) With $v = 0.98c$, the momentum is

$$
p = \frac{m_0 v}{\sqrt{1 - \frac{v^2}{c^2}}} = \frac{m_0 v}{\sqrt{1 - \frac{(0.98c)^2}{c^2}}} = \frac{m_0 v}{\sqrt{1 - (0.98)^2}} = 5.0 m_0 v
$$

An electron traveling at 98% the speed of light has $\gamma = 5.0$ and a momentum 5.0 times its classical value.

26-8 The Ultimate Speed

A basic result of the special theory of relativity is that the speed of an object cannot equal or exceed the speed of light. That the speed of light is a natural speed limit in the universe can be seen from any of Eqs. $26-1$, $26-3$, or $26-4$. It is perhaps easiest to see from Eq. 26–4: as an object is accelerated to greater and greater speeds, its momentum becomes larger and larger. Indeed, if v were to equal c , the denominator in this equation would be zero (in the other equations too), and the momentum would become infinite. To accelerate an object up to $v = c$ would thus require infinite energy, and so is not possible.

26-9 $E = mc^2$; Mass and Energy

If momentum needs to be modified to fit with relativity as we just saw in Eq. 26–4, then we might expect energy too would need to be rethought. Indeed, Einstein not only developed a new formula for kinetic energy, but also found a new relation between mass and energy, and the startling idea that mass is a form of energy.¹

We can start with the work–energy principle (Chapter 6) and assume it is still valid in relativity. That is, the net work done on a particle is equal to its change in kinetic energy (KE). Using this principle, Einstein showed that at high speeds the formula $KE = \frac{1}{2}mv^2$ is not correct. Instead, Einstein showed that the kinetic energy of a particle of rest mass m_0 traveling at speed v is given by

Relativistic kinetic energy

$$
KE = \frac{m_0 c^2}{\sqrt{1 - v^2/c^2}} - m_0 c^2.
$$
 (26-6a)

In terms of $\gamma = 1/\sqrt{1 - v^2/c^2}$ we can rewrite Eq. 26–6a as

$$
KE = \gamma m_0 c^2 - m_0 c^2 = (\gamma - 1) m_0 c^2. \tag{26-6b}
$$

Equations 26–6 require some interpretation. The first term increases with the speed v of the particle. The second term, m_0c^2 , is constant; it is called the **rest** energy E_0 of the particle, and represents a form of energy that a particle has even when at rest. Note that if a particle is at rest ($v = 0$) the first term in Eq. 26–6a becomes m_0c^2 , so $KE = 0$ as it should.

We can rearrange Eq. 26–6b to get

$$
\gamma m_0 c^2 = m_0 c^2 + \text{KE}.
$$

We call $\gamma m_0 c^2$ the *total energy E* of the particle (assuming no potential energy), because it equals the rest energy plus the kinetic energy:

Total energy (defined)

$$
E = m_0 c^2 + \text{KE.}
$$
 (26-7a)

The total energy can also be written, using Eqs. 26–6, as

$$
E = \gamma m_0 c^2 = \frac{m_0 c^2}{\sqrt{1 - v^2/c^2}}.
$$
 (26-7b)

For a particle at rest in a given reference frame, KE is zero in Eqs. 26-7, so the total energy is its rest energy E_0 :

$$
E_0 = m_0 c^2. \tag{26-8}
$$

Here we have Einstein's famous formula, usually written simply as $E = mc^2$. This formula mathematically relates the concepts of energy and mass. But if this idea is to have any meaning from a practical point of view, then mass ought to be convertible to other forms of energy and vice versa. Einstein suggested that this might be possible, and indeed changes of mass to other forms of energy, and vice versa, have been experimentally confirmed countless times. The interconversion of mass and energy is most easily detected in nuclear and elementary particle physics. For example, the neutral pion (π^0) of rest mass 2.4 \times 10⁻²⁸ kg is observed to decay into pure electromagnetic radiation (photons). The π^0 completely disappears in the process. The amount of electromagnetic energy produced is found to be exactly equal to that predicted by Einstein's formula, $E = mc^2$. The reverse process is also commonly observed in the laboratory: electromagnetic radiation under certain conditions can be converted into material particles such as electrons (see Section 27-6 on pair production).

[†]The concept of mass being a form of energy emerges nicely from the concept of relativistic mass, Eq. 26-5. When work is done on an object, its kinetic energy increases. The object's speed cannot increase indefinitely because it cannot exceed c ; but the object's relativistic mass increases. That is, the work done on an object not only increases its speed but also contributes to increasing its mass.

Mass and energy interchangeable On a larger scale, the energy produced in nuclear power plants is a result of the loss in rest mass of the uranium fuel as it undergoes the process called fission (Chapter 31). Even the radiant energy we receive from the Sun is an example of $E = mc^2$; the Sun's mass is continually decreasing as it radiates electromagnetic energy outward.

The relation $E = mc^2$ is now believed to apply to all processes, although the changes are often too small to measure. That is, when the energy of a system changes by an amount ΔE , the mass of the system changes by an amount Δm given by

$$
\Delta E = (\Delta m)(c^2). \tag{26-9}
$$

In a nuclear reaction where an energy E is released (or required to make it go), the masses of the reactants and the products will be different by $\Delta m = \Delta E/c^2$. Even when water is heated on a stove, the mass of the water is assumed to increase very slightly.

EXAMPLE 26-8 Pion's KE. A π^0 meson $(m_0 = 2.40 \times 10^{-28} \text{ kg})$ travels at a speed $v = 0.80c = 2.4 \times 10^8$ m/s. What is its kinetic energy? Compare to a classical calculation.

APPROACH Relativistically, kinetic energy is given by Eqs. 26–6. Classically, $KE = \frac{1}{2} m_0 v^2$.

SOLUTION The kinetic energy of our π^0 meson at speed $v = 0.80c$ is $(Eq. 26-6a)$:

$$
\begin{aligned} \n\text{KE} &= m_0 c^2 \bigg(\frac{1}{\sqrt{1 - v^2/c^2}} - 1 \bigg) \\ \n&= (2.40 \times 10^{-28} \, \text{kg}) (3.0 \times 10^8 \, \text{m/s})^2 \bigg(\frac{1}{(1 - 0.64)^{\frac{1}{2}}} - 1 \bigg) \\ \n&= 1.4 \times 10^{-11} \, \text{J.} \n\end{aligned}
$$

PROBLEM SOLVING Relativistic KE

Notice that the units of m_0c^2 are kg·m²/s², which is the joule. A classical calculation would give $KE = \frac{1}{2}m_0v^2 = \frac{1}{2}(2.4 \times 10^{-28} \text{ kg})(2.4 \times 10^8 \text{ m/s})^2 = 6.9 \times 10^{-12} \text{ J}$, about half as much, but this is not a correct result.

NOTE Do not try to calculate the relativistic kinetic energy by using the classical equation with a relativistic mass instead of the rest mass (here $m_{\text{rel}} = m_0 / \sqrt{1 - v^2/c^2} = 4.0 \times 10^{-28} \text{ kg}$. This would give $\kappa E = \frac{1}{2}mv^2 = \frac{1}{2}(4.0 \times 10^{-28} \text{ kg})(2.4 \times 10^8 \text{ m/s})^2 = 1.2 \times 10^{-11} \text{ J}$, which is incorrect.

EXAMPLE 26-9 Energy from nuclear decay. The energy required or released in nuclear reactions and decays comes from a change in mass between the initial and final particles. In one type of radioactive decay (Chapter 30), an atom of uranium $(m = 232.03714 \text{ u})$ decays to an atom of thorium ($m = 228.02873$ u) plus an atom of helium ($m = 4.00260$ u) where the masses given are in atomic mass units $(1 u = 1.6605 \times 10^{-27} kg)$. Calculate the energy released in this decay.

APPROACH The initial mass minus the total final mass gives the mass loss in atomic mass units (u); we convert that to kg, and multiply by $c²$ to find the energy released, $\Delta E = \Delta m c^2$.

SOLUTION The initial mass is 232.03714 u, and after the decay the mass is $228.02873 u + 4.00260 u = 232.03133 u$, so there is a decrease in mass of 0.00581 u. This mass, which equals $(0.00581 \text{ u})(1.66 \times 10^{-27} \text{ kg})$ = 9.64×10^{-30} kg, is changed into energy. By $\Delta E = \Delta m c^2$, we have

$$
\Delta E = (9.64 \times 10^{-30} \,\text{kg})(3.0 \times 10^8 \,\text{m/s})^2 = 8.68 \times 10^{-13} \,\text{J}
$$

Since $1 \text{ MeV} = 1.60 \times 10^{-13} \text{ J}$, the energy released is 5.4 MeV.

Energy released in nuclear process

EXAMPLE 26-10 Mass change in a chemical reaction. When two moles of hydrogen and one mole of oxygen react to form two moles of water, the energy released is 484 kJ. How much does the mass decrease in this reaction?

APPROACH We use Einstein's great concept of the interchangeability of mass and energy $(E = mc^2)$.

SOLUTION Using Eq. 26-9 we have for the change in mass Δm :

$$
\Delta m = \frac{\Delta E}{c^2} = \frac{(-484 \times 10^3 \text{ J})}{(3.00 \times 10^8 \text{ m/s})^2} = -5.38 \times 10^{-12} \text{ kg}
$$

The initial mass of the system is $0.002 \text{ kg} + 0.016 \text{ kg} = 0.018 \text{ kg}$. Thus the change in mass is relatively very tiny and can normally be neglected. [Conservation of mass is usually a reasonable principle to apply to chemical reactions.]

Units: $\frac{eV}{c}$ for p
eV/ c^2 for m

In the tiny world of atoms and nuclei, it is common to quote energies in eV (electron volts) or multiples such as MeV (10^6 eV) . Momentum (see Eq. 26–4) can be quoted in units of eV/c (or MeV/c). And mass can be quoted (from $E = mc^2$) in units of eV/c² (or MeV/c²). Note the use of c to keep the units correct. The rest masses of the electron and the proton are readily shown to be $0.511 \text{ MeV}/c^2$ and 938 MeV/ c^2 , respectively. See also the Table inside the front cover.

EXAMPLE 26-11 A 1-TeV proton. The Tevatron accelerator at Fermilab in Illinois can accelerate protons to a kinetic energy of $1.0 \,\text{TeV}$ ($10^{12} \,\text{eV}$). What is the speed of such a proton?

APPROACH We solve the kinetic energy formula, Eq. 26–6a, for v .

SOLUTION The rest energy of a proton is $E_0 = 938 \text{ MeV}$ or $9.38 \times 10^8 \text{ eV}$. Compared to the KE of 10^{12} eV, the rest energy can be neglected, so we simplify Eq. 26-6a to

$$
\text{KE} \approx \frac{m_0 c^2}{\sqrt{1 - v^2/c^2}}.
$$

We solve this for v in the following steps:

$$
\sqrt{1 - \frac{v^2}{c^2}} = \frac{m_0 c^2}{\text{KE}};
$$

\n
$$
1 - \frac{v^2}{c^2} = \left(\frac{m_0 c^2}{\text{KE}}\right)^2;
$$

\n
$$
\frac{v^2}{c^2} = 1 - \left(\frac{m_0 c^2}{\text{KE}}\right)^2 = 1 - \left(\frac{9.38 \times 10^8 \text{ eV}}{1.0 \times 10^{12} \text{ eV}}\right)^2;
$$

\n
$$
v = \sqrt{1 - (9.38 \times 10^{-4})^2} \, c = 0.99999956c.
$$

So the proton is traveling at a speed very nearly equal to c .

At low speeds, $v \ll c$, the relativistic formula for KE reduces to the classical one, as we show by using the binomial expansion, $(1 \pm x)^n$ = $1 \pm nx + n(n-1)x^2/2! + \cdots$. With $n = -\frac{1}{2}$, we expand the square root in Eq. 26-6a

$$
KE = m_0 c^2 \left(\frac{1}{\sqrt{1 - v^2/c^2}} - 1 \right)
$$

so that

$$
\mathbf{KE} \approx m_0 c^2 \bigg(1 + \frac{1}{2} \frac{v^2}{c^2} + \dots - 1 \bigg)
$$

$$
\approx \frac{1}{2} m_0 v^2.
$$

The dots in the first expression represent very small terms in the expansion which we neglect since we assumed that $v \ll c$. Thus at low speeds, the relativistic form for kinetic energy reduces to the classical form, $KE = \frac{1}{2}mv^2$. This makes relativity a viable theory in that it can predict accurate results at low speed as well as at high. Indeed, the other equations of special relativity also reduce to their classical equivalents at ordinary speeds: length contraction, time dilation, and modifications to momentum as well as kinetic energy, all disappear for $v \ll c$ since $\sqrt{1 - v^2/c^2} \approx 1$.

A useful relation between the total energy E of a particle and its momentum p can also be derived. The momentum of a particle of rest mass m_0 and speed v is given by Eq. 26-4:

$$
p = \frac{m_0 v}{\sqrt{1 - v^2/c^2}} = \gamma m_0 v.
$$

Relativistic momentum

(26-10) Energy related to momentum

The total energy is $(Eq. 26-7b)$

$$
E = \gamma m_0 c^2 = \frac{m_0 c^2}{\sqrt{1 - v^2/c^2}}.
$$

We square this equation (and add a term " $v^2 - v^{2}$ " which is zero, but will help us):

$$
E^{2} = \frac{m_{0}^{2}c^{2}(v^{2} - v^{2} + c^{2})}{1 - v^{2}/c^{2}}
$$

$$
= p^{2}c^{2} + \frac{m_{0}^{2}c^{4}(1 - v^{2}/c^{2})}{1 - v^{2}/c^{2}}
$$

or

$$
E^2 = p^2c^2 + m_0^2c^4.
$$

Thus, the total energy can be written in terms of the momentum p , or in terms of the kinetic energy (Eq. $26-7a$), where we have assumed there is no potential energy.

* When Do We Use Relativistic Formulas?

From a practical point of view, we do not have much opportunity in our daily lives to use the mathematics of relativity. For example, the γ factor, $\gamma = 1/\sqrt{1 - v^2/c^2}$, which appears in many relativistic formulas, has a value of 1.005 when $v = 0.10c$. Thus, for speeds even as high as $0.10c = 3.0 \times 10^7$ m/s, the factor $\sqrt{1-v^2/c^2}$ in relativistic formulas gives a numerical correction of less than 1% . For speeds less than 0.10c, or unless mass and energy are interchanged, we don't usually need to use the more complicated relativistic formulas, and can use the simpler classical formulas.

If you are given a particle's rest mass m_0 and its kinetic energy KE, you can do a quick calculation to determine if you need to use relativistic formulas or if classical ones are good enough. You simply compute the ratio KE/m_0c^2 because $(Eq. 26-6b)$

$$
\frac{\text{KE}}{m_0 c^2} = \gamma - 1 = \frac{1}{\sqrt{1 - v^2/c^2}} - 1.
$$

If this ratio comes out to be less than, say, 0.01, then $\gamma \le 1.01$ and relativistic equations will correct the classical ones by about 1% . If your expected precision is no better than 1% , classical formulas are good enough. But if your precision is 1 part in 1000 (0.1%) then you would want to use relativistic formulas. If your expected precision is only 10%, you need relativity if $(\kappa E/m_0c^2) \gtrsim 0.1$.

EXERCISE E For 1% accuracy, does an electron with $KE = 100 eV$ need to be treated relativistically? [*Hint*: the rest mass of an electron is 0.511 MeV.]

26-10 Relativistic Addition of Velocities

Consider a rocket ship that travels away from the Earth with speed v , and assume that this rocket has fired off a second rocket that travels at speed u' with respect to the first (Fig. 26–10). We might expect that the speed u of rocket 2 with respect to Earth is $u = v + u'$, which in the case shown in Fig. 26–10 is $u = 0.60c + 0.60c = 1.20c$. But, as discussed in Section 26–8, no object can travel faster than the speed of light in any reference frame. Indeed, Einstein showed that since length and time are different in different reference frames, the old addition-of-velocities formula is no longer valid. Instead, the correct formula is

> $u = \frac{v + u'}{1 + vu'/c^2}$ $\begin{bmatrix} \vec{u} \text{ and } \vec{v} \text{ along} \\ \text{the same direction} \end{bmatrix}$ $(26-11)$

for motion along a straight line. We derive this formula in Appendix E. If u' is in the opposite direction from v , then u' must have a minus sign in the above equation so $u = (v - u')/(1 - vu'/c^2)$.

EXAMPLE 26-12 Relative velocity, relativistically. Calculate the speed of rocket 2 in Fig. $26-10$ with respect to Earth.

APPROACH We add the speed of rocket 2 relative to rocket 1, to the speed of rocket 1 relative to Earth, using the relativistic Eq. $26-11$ because the speeds are high and they are along the same line.

SOLUTION Rocket 2 moves with speed $u' = 0.60c$ with respect to rocket 1. Rocket 1 has speed $v = 0.60c$ with respect to Earth. The speed of rocket 2 with respect to Earth is $(Eq. 26-11)$

$$
u = \frac{0.60c + 0.60c}{1 + \frac{(0.60c)(0.60c)}{c^2}} = \frac{1.20c}{1.36} = 0.88c.
$$

NOTE The speed of rocket 2 relative to Earth is found to be less than c , as it must be.

We can see that Eq. $26-11$ reduces to the classical form for velocities small compared to the speed of light since $1 + vu'/c^2 \approx 1$ for v and $u' \ll c$. Thus, $u \approx v + u'$, as in classical physics (Chapter 3).

Let us test our formula in one more case, that of the speed of light. Suppose that rocket 1 in Fig. 26–10 sends out a beam of light so that $u' = c$. Equation 26–11 tells us that the speed of this light with respect to Earth is

$$
u = \frac{0.60c + c}{1 + \frac{(0.60c)(c)}{c^2}} = \frac{1.60c}{1.60} = c,
$$

which is fully consistent with the second postulate of relativity.

EXERCISE F Use Eq. 26-11 to calculate the speed of rocket 2 in Fig. 26-10 relative to Earth if it was shot from rocket 1 at a speed $u' = 3000 \text{ km/s} = 0.010c$. Assume rocket 1 had a speed $v = 6000 \text{ km/s} = 0.020c$.

26-11 The Impact of Special Relativity

A great many experiments have been performed to test the predictions of the special theory of relativity. Within experimental error, no contradictions have been found. Scientists have therefore accepted relativity as an accurate description of nature.

CAUTION

Relative velocities do

in classical ($v \ll c$) mechanics

Relativistic addition of velocities

formula (\vec{u} and \vec{v} along same line)

not add simply, as

FIGURE 26-10 Rocket 2 is fired from rocket 1 with speed $u' = 0.60c$. What is the speed of rocket 2 with respect to the Earth?

At speeds much less than the speed of light, the relativistic formulas reduce to the old classical ones, as we have discussed. We would, of course, hope—or rather, insist—that this be true since Newtonian mechanics works so well for objects moving with speeds $v \ll c$. This insistence that a more general theory (such as relativity) give the same results as a more restricted theory (such as classical mechanics which works for $v \ll c$) is called the correspondence principle. The two theories must correspond where their realms of validity overlap. Relativity thus does not contradict classical mechanics. Rather, it is a more general theory, of which classical mechanics is now considered to be a limiting case.

The importance of relativity is not simply that it gives more accurate results, especially at very high speeds. Much more than that, it has changed the way we view the world. The concepts of space and time are now seen to be relative, and intertwined with one another, whereas before they were considered absolute and separate. Even our concepts of matter and energy have changed: either can be converted to the other. The impact of relativity extends far beyond physics. It has influenced the other sciences, and even the world of art and literature; it has, indeed, entered the general culture.

From a practical point of view, we do not have much opportunity in our daily lives to use the mathematics of relativity. For example, the γ factor $1/\sqrt{1-v^2/c^2}$, which appears in relativistic formulas, has a value of only 1.005 even for a speed as high as $0.10c = 3.0 \times 10^7$ m/s, giving a correction of less than 1% . For speeds less than 0.10c, or unless mass and energy are interchanged, we don't usually need to use the more complicated relativistic formulas, and can use the simpler classical formulas.

The special theory of relativity we have studied in this Chapter deals with inertial (nonaccelerating) reference frames. In Chapter 33 we will discuss briefly the more complicated "general theory of relativity" which can deal with noninertial reference frames.

Correspondence principle

Summary

An inertial reference frame is one in which Newton's law of inertia holds. Inertial reference frames can move at constant velocity relative to one another; accelerating reference frames are noninertial.

The special theory of relativity is based on two principles: the relativity principle, which states that the laws of physics are the same in all inertial reference frames, and the principle of the constancy of the speed of light, which states that the speed of light in empty space has the same value in all inertial reference frames.

One consequence of relativity theory is that two events that are simultaneous in one reference frame may not be simultaneous in another. Other effects are time dilation: moving clocks are measured to run slow; and length contraction: the length of a moving object is measured to be shorter (in its direction of motion) than when it is at rest. Quantitatively,

$$
\Delta t = \frac{\Delta t_0}{\sqrt{1 - v^2/c^2}} = \gamma \Delta t_0 \tag{26-1}
$$

$$
L = L_0 \sqrt{1 - v^2/c^2} = \frac{L_0}{\gamma}
$$
 (26-3)

where L and Δt are the length and time interval of objects

(or events) observed as they move by at the speed v; L_0 and Δt_0 are the proper length and proper time—that is, the same quantities as measured in the rest frame of the objects or events. The quantity γ is shorthand for

$$
\gamma = \frac{1}{\sqrt{1 - v^2/c^2}}.
$$
 (26-2)

The theory of relativity has changed our notions of space and time, and of momentum, energy, and mass. Space and time are seen to be intimately connected, with time being the fourth dimension in addition to the three dimensions of space.

The momentum of an object is given by

$$
p = \gamma m_0 v = \frac{m_0 v}{\sqrt{1 - v^2/c^2}}.
$$
 (26-4)

This formula can be interpreted as a mass increase, where the relativistic mass is

$$
m_{\text{rel}} = \gamma m_0 = \frac{m_0}{\sqrt{1 - v^2/c^2}},
$$
 (26-5)

and m_0 is the **rest mass** of the object $(v = 0)$.

Summary 749

Mass and energy are interconvertible. The equation

$$
E_0 = m_0 c^2 \tag{26-8}
$$

tells how much energy E_0 is needed to create a mass m_0 , or vice versa. Said another way, $E_0 = m_0 c^2$ is the amount of energy an object has because of its mass m_0 . The law of conservation of energy must include mass as a form of energy.

The kinetic energy KE of an object moving at speed v is given by

$$
KE = \frac{m_0 c^2}{\sqrt{1 - v^2/c^2}} - m_0 c^2 = (\gamma - 1)m_0 c^2 \qquad (26-6)
$$

where m_0 is the rest mass of the object. The total energy E ,

Questions

- 1. You are in a windowless car in an exceptionally smooth train moving at constant velocity. Is there any physical experiment you can do in the train car to determine whether you are moving? Explain.
- 2. You might have had the experience of being at a red light when, out of the corner of your eye, you see the car beside you creep forward. Instinctively you stomp on the brake pedal, thinking that you are rolling backward. What does this say about absolute and relative motion?
- 3. A worker stands on top of a moving railroad car, and throws a heavy ball straight up (from his point of view). Ignoring air resistance, will the ball land on the car or behind it?
- 4. Does the Earth really go around the Sun? Or is it also valid to say that the Sun goes around the Earth? Discuss in view of the first principle of relativity (that there is no best reference frame). Explain.
- 5. If you were on a spaceship traveling at $0.5c$ away from a star, at what speed would the starlight pass you?
- 6. The time dilation effect is sometimes expressed as "moving clocks run slowly." Actually, this effect has nothing to do with motion affecting the functioning of clocks. What then does it deal with?
- 7. Does time dilation mean that time actually passes more slowly in moving reference frames or that it only seems to pass more slowly?
- 8. A young-looking woman astronaut has just arrived home from a long trip. She rushes up to an old gray-haired man and in the ensuing conversation refers to him as her son. How might this be possible?
- 9. If you were traveling away from Earth at speed $0.5c$, would you notice a change in your heartbeat? Would your mass, height, or waistline change? What would observers on Earth using telescopes say about you?
- 10. Do time dilation and length contraction occur at ordinary speeds, say 90 km/h?
- 11. Suppose the speed of light were infinite. What would happen to the relativistic predictions of length contraction and time dilation?
- 12. Discuss how our everyday lives would be different if the speed of light were only 25 m/s.

750 CHAPTER 26 The Special Theory of Relativity

if there is no potential energy, is

$$
E = \text{KE} + m_0 c^2
$$

= $\gamma m_0 c^2$. (26-7)

The momentum p of an object is related to its total energy E (assuming no potential energy) by

$$
E^2 = p^2 c^2 + m_0^2 c^4. \tag{26-10}
$$

Velocity addition also must be done in a special way. All these relativistic effects are significant only at high speeds, close to the speed of light, which itself is the ultimate speed in the universe.

- 13. Explain how the length contraction and time dilation formulas might be used to indicate that c is the limiting speed in the universe.
- 14. The drawing at the start of this Chapter shows the street as seen by Mr Tompkins, for whom the speed of light is $c = 20$ mi/h. What does Mr Tompkins look like to the people standing on the street (Fig. 26-11)? Explain.

FIGURE 26-11 Question 14. Mr Tompkins as seen by people on the sidewalk. See also Chapter-opening photograph.

- **15.** An electron is limited to travel at speeds less than c . Does this put an upper limit on the momentum of an electron? If so, what is this upper limit? If not, explain.
- 16. Can a particle of nonzero rest mass attain the speed of light?
- 17. Does the equation $E = mc^2$ conflict with the conservation of energy principle? Explain.
- 18. If mass is a form of energy, does this mean that a spring has more mass when compressed than when relaxed?
- 19. It is not correct to say that "matter can neither be created nor destroyed." What must we say instead?
- 20. Is our intuitive notion that velocities simply add, as we did in Section 3-8, completely wrong?

Problems

26-4 and 26-5 Time Dilation, Length Contraction

- 1. (I) A spaceship passes you at a speed of $0.750c$. You measure its length to be 28.2 m. How long would it be when at rest?
- 2. (I) A certain type of elementary particle travels at a speed of 2.70×10^8 m/s. At this speed, the average lifetime is measured to be 4.76×10^{-6} s. What is the particle's lifetime at rest?
- 3. (I) Lengths and time intervals depend on the factor

$$
\sqrt{1-v^2/c^2}
$$

according to the theory of relativity (Eqs. 26-1 and 26-3). Evaluate this factor for speeds of: (a) $v = 20,000 \text{ m/s}$ (typical speed of a satellite); (b) $v = 0.020c$; (c) $v = 0.200c$; (d) $v = 0.95c$; (e) $v = 0.98c$; (f) $v = 0.999c$.

- 4. (II) If you were to travel to a star 125 light-years from Earth at a speed of 2.50×10^8 m/s, what would you measure this distance to be?
- 5. (II) What is the speed of a pion if its average lifetime is measured to be 4.10×10^{-8} s? At rest, its average lifetime is 2.60×10^{-8} s.
- 6. (II) In an Earth reference frame, a star is 82 light-years away. How fast would you have to travel so that to you the distance would be only 35 light-years?
- 7. (II) Suppose you decide to travel to a star 85 light-years away at a speed that tells you the distance is only 25 lightyears. How many years would it take you to make the trip?
- 8. (II) At what speed v will the length of a 1.00-m stick look 10.0% shorter (90.0 cm)?
- 9. (II) Escape velocity from the Earth is $40,000 \text{ km/h}$. What would be the percent decrease in length of a 95.2-m-long spacecraft traveling at that speed?
- 10. (II) At what speed do the relativistic formulas for (a) length and (b) time intervals differ from classical values by 1.00% ? (This is a reasonable way to estimate when to do relativistic calculations rather than classical.)
- 11. (II) Suppose a news report stated that starship *Enterprise* had just returned from a 5-year voyage while traveling at $0.84c$. (a) If the report meant 5.0 years of *Earth time*, how much time elapsed on the ship? (b) If the report meant 5.0 years of *ship time*, how much time passed on Earth?
- 12. (II) A certain star is 10.6 light-years away. How long would it take a spacecraft traveling $0.960c$ to reach that star from Earth, as measured by observers: (a) on Earth, (b) on the spacecraft? (c) What is the distance traveled according to observers on the spacecraft? (d) What will the spacecraft occupants compute their speed to be from the results of (b) and (c) ?
- 13. (II) A friend speeds by you in her "Ferrari" spacecraft at a speed of 0.660c. It is measured in your frame to be 4.80 m long and 1.25 m high. (a) What will be its length and height at rest? (b) How many seconds would you say elapsed on your friend's watch when 20.0 s passed on yours? (c) How fast did you appear to be traveling according to your friend? (d) How many seconds would she say elapsed on your watch when she saw 20.0 s pass on hers?

14. (III) How fast must an average pion be moving to travel 15 m before it decays? The average lifetime, at rest, is 2.6×10^{-8} s.

26-7 Relativistic Momentum

- 15. (I) What is the momentum of a proton traveling at $v = 0.85c$?
- 16. (I) At what speed will an object's relativistic mass be twice its rest mass?
- 17. (II) A particle of rest mass m_0 travels at a speed $v = 0.20c$. At what speed will its momentum be doubled?
- **18.** (II) (a) A particle travels at $v = 0.10c$. By what percentage will a calculation of its momentum be wrong if you use the classical formula? (b) Repeat for $v = 0.50c$.
- 19. (II) What is the percent change in momentum of a proton that accelerates (a) from $0.45c$ to $0.90c$, (b) from $0.90c$ to $0.98c$?

$26-9$ $E = mc^2$

- **20.** (I) A certain chemical reaction requires 4.82×10^4 J of energy input for it to go. What is the increase in mass of the products over the reactants?
- 21. (I) When a uranium nucleus at rest breaks apart in the process known as fission in a nuclear reactor, the resulting fragments have a total kinetic energy of about 200 MeV. How much mass was lost in the process?
- 22. (I) Calculate the rest energy of an electron in joules and in MeV (1 MeV = 1.60×10^{-13} J).
- 23. (I) Calculate the rest mass of a proton in MeV/ c^2 .
- 24. (I) The total annual energy consumption in the United States is about 8×10^{19} J. How much mass would have to be converted to energy to fuel this need?
- 25. (II) How much energy can be obtained from conversion of 1.0 gram of mass? How much mass could this energy raise to a height of 0.25 km above the Earth's surface?
- 26. (II) What is the speed of a particle when its kinetic energy equals its rest energy?
- 27. (II) At what speed will an object's kinetic energy be 25% of its rest energy?
- $28.$ (II) (*a*) How much work is required to accelerate a proton from rest up to a speed of $0.997c$? (b) What would be the momentum of this proton?
- 29. (II) Calculate the kinetic energy and momentum of a proton traveling 2.60×10^8 m/s.
- 30. (II) What is the momentum of a 750 -MeV proton (that is, its kinetic energy is 750 MeV)?
- 31. (II) What is the speed of a proton accelerated by a potential difference of 105 MV?
- 32. (II) What is the speed of an electron whose kinetic energy is 1.00 MeV?
- 33. (II) What is the speed of an electron just before it hits a television screen after being accelerated from rest by the 25,000 V of the picture tube?
- 34. (II) Two identical particles of rest mass m_0 approach each other at equal and opposite speeds, v . The collision is completely inelastic and results in a single particle at rest. What is the rest mass of the new particle? How much energy was lost in the collision? How much kinetic energy is lost in this collision?
- 35. (II) Calculate the speed of a proton $(m_0 = 1.67 \times 10^{-27} \text{ kg})$ whose kinetic energy is exactly half (a) its total energy, (b) its rest energy.
- 36. (II) What is the speed and the momentum of an electron $(m = 9.11 \times 10^{-31}$ kg) whose kinetic energy equals its rest energy?
- 37. (II) Suppose a spacecraft of mass 27,000 kg is accelerated to $0.21c$. (a) How much kinetic energy would it have? (b) If you used the classical formula for kinetic energy, by what percentage would you be in error?
- 38. (II) Calculate the kinetic energy and momentum of a proton $(m_0 = 1.67 \times 10^{-27} \text{ kg})$ traveling 7.35 × 10⁷ m/s. By what percentages would your calculations have been in error if you had used classical formulas?
- 39. (II) The americium nucleus, $^{241}_{95}$ Am, decays to a neptunium nucleus, $^{237}_{93}$ Np, by emitting an alpha particle of mass 4.00260 u and kinetic energy 5.5 MeV. Estimate the mass of the neptunium nucleus, ignoring its recoil, given that the americium mass is 241.05682 u.
- 40. (II) An electron $(m_0 = 9.11 \times 10^{-31} \text{ kg})$ is accelerated from rest to speed v by a conservative force. In this process, its potential energy decreases by 6.60×10^{-14} J. Determine the electron's speed, v .
- 41. (II) Make a graph of the kinetic energy versus momentum for (a) a particle of nonzero rest mass, and (b) a particle with zero rest mass.
- 42. (II) What magnetic field intensity is needed to keep 998-GeV protons revolving in a circle of radius 1.0 km (at, say, the Fermilab synchrotron)? Use the relativistic mass. The proton's rest mass is 0.938 GeV/ c^2 . (1 GeV = 10⁹ eV.) [*Hint*: in relativity, it is still true that $mv^2/r = qvB$ in a magnetic field.]

General Problems

- 49. The nearest star to Earth is Proxima Centauri, 4.3 lightyears away. (a) At what constant velocity must a spacecraft travel from Earth if it is to reach the star in 4.0 years, as measured by travelers on the spacecraft? (b) How long does the trip take according to Earth observers?
- 50. As a rule of thumb, anything traveling faster than about $0.1c$ is called *relativistic*—i.e., for which the correction using special relativity is a significant effect. Determine the speed of an electron in a hydrogen atom (radius 0.5×10^{-10} m) and state if it is relativistic. (Treat the electron as though it were in a circular orbit around the proton.)

26-10 Relativistic Addition of Velocities

- 43. (I) A person on a rocket traveling at $0.50c$ (with respect to the Earth) observes a meteor come from behind and pass her at a speed she measures as 0.50c. How fast is the meteor moving with respect to the Earth?
- 44. (II) Two spaceships leave Earth in opposite directions, each with a speed of $0.50c$ with respect to Earth. (a) What is the velocity of spaceship 1 relative to spaceship 2? (b) What is the velocity of spaceship 2 relative to spaceship 1?
- 45. (II) A spaceship leaves Earth traveling at 0.71c. A second spaceship leaves the first at a speed of 0.87c with respect to the first. Calculate the speed of the second ship with respect to Earth if it is fired (a) in the same direction the first spaceship is already moving, (b) directly backward toward Earth.
- 46. (II) An observer on Earth sees an alien vessel approach at a speed of 0.60c. The *Enterprise* comes to the rescue (Fig. 26-12), overtaking the aliens while moving directly toward Earth at a speed of 0.90c relative to Earth. What is the relative speed of one vessel as seen by the other?

FIGURE 26-12 Problem 46.

- 47. (II) A spaceship in distress sends out two escape pods in opposite directions. One travels at a speed $v_1 = -0.60c$ in one direction, and the other travels at a speed $v_2 = +0.70c$ in the other direction, as observed from the spaceship. What speed does the first escape pod measure for the second escape pod?
- 48. (II) Rocket A passes Earth at a speed of 0.75c. At the same time, rocket B passes Earth moving 0.95c relative to Earth in the same direction. How fast is B moving relative to A when it passes A?
- 51. (a) What is the speed v of an electron whose kinetic energy is 14,000 times its rest energy? You can state the difference, $c - v$. Such speeds are reached in the Stanford Linear Accelerator, SLAC. (b) If the electrons travel in the lab through a tube 3.0 km long (as at SLAC), how long is this tube in the electrons' reference frame? [*Hint*: use the binomial expansion.]
- 52. How many grams of matter would have to be totally destroyed to run a 100-W lightbulb for 1 year?
- 53. What minimum amount of electromagnetic energy is needed to produce an electron and a positron together? A positron is a particle with the same rest mass as an electron, but has the opposite charge. (Note that electric charge is conserved in this process. See Section 27–6.)
- 54. An electron $(m = 9.11 \times 10^{-31} \text{ kg})$ enters a uniform magnetic field $B = 1.8$ T, and moves perpendicular to the field lines with a speed $v = 0.92c$. What is the radius of curvature of its path? See hint for Problem 42.
- 55. A negative muon traveling at 33% the speed of light collides head on with a positive muon traveling at 50% the speed of light. The two muons (each of rest mass $105.7 \text{MeV}/c^2$) annihilate, and produce how much electromagnetic energy?
- 56. A free neutron can decay into a proton, an electron, and a neutrino. Assume the neutrino's rest mass is zero, and the other masses can be found in the Table inside the front cover. Determine the total kinetic energy shared among the three particles when a neutron decays at rest.
- 57. The Sun radiates energy at a rate of about 4×10^{26} W. (a) At what rate is the Sun's mass decreasing? (b) How long does it take for the Sun to lose a mass equal to that of Earth? (c) Estimate how long the Sun could last if it radiated constantly at this rate.
- 58. An unknown particle is measured to have a negative charge and a speed of 2.24×10^8 m/s. Its momentum is determined to be 3.07×10^{-22} kg·m/s. Identify the particle by finding its rest mass.
- 59. How much energy would be required to break a helium nucleus into its constituents, two protons and two neutrons? The rest masses of a proton (including an electron), a neutron, and helium are, respectively, 1.00783 u, 1.00867 u, and 4.00260 u. (This energy difference is called the *total binding energy* of the ⁴He nucleus.)
- 60. What is the percentage increase in the (relativistic) mass of a car traveling 110 km/h as compared to at rest? [Hint: use the binomial expansion.]
- 61. Two protons, each having a speed of $0.935c$ in the laboratory, are moving toward each other. Determine (a) the momentum of each proton in the laboratory, (b) the total momentum of the two protons in the laboratory, and (c) the momentum of one proton as seen by the other proton.
- 62. Show analytically that a particle with momentum p and energy E has a speed given by

$$
v = \frac{pc^2}{E} = \frac{pc}{\sqrt{m_0^2 c^2 + p^2}}.
$$

- 63. The fictional starship *Enterprise* obtains its power by combining matter and antimatter, achieving complete conversion of mass into energy. If the mass of the *Enterprise* is approximately 5×10^9 kg, how much mass must be converted into kinetic energy to accelerate it from rest to one-tenth the speed of light?
- 64. An electron is accelerated so that its kinetic energy is greater than its rest energy m_0c^2 by a factor of (a) 5.00, (b) 999. What is the speed of the electron in each case?

Answers to Exercises

- 65. A farm boy studying physics believes that he can fit a 15.0-m-long pole into a 12.0-m-long barn if he runs fast enough (carrying the pole). Can he do it? Explain in detail. How does this fit with the idea that when he is running the barn looks even shorter to him than 12.0 m?
- 66. When two moles of hydrogen and one mole of oxygen react to form two moles of water, the energy released is 484 kJ. How much does the mass of the elements decrease in this reaction? What % of the total original mass of the system does this mass change represent?
- 67. In a nuclear reaction two identical particles are created, traveling in opposite directions. If the speed of each particle is 0.75c, relative to the laboratory frame of reference, what is one particle's speed relative to the other particle?
- 68. An astronaut on a spaceship traveling at $0.75c$ relative to Earth measures his ship to be 25 m long. On the ship, he eats his lunch in 23 min. (a) What length is the spaceship according to observers on Earth? (b) How long does the astronaut's lunch take to eat according to observers on Earth?
- 69. You are traveling in a spaceship at a speed of $0.85c$ away from Earth. You send a laser beam toward the Earth traveling at velocity c relative to you. What do observers on the Earth measure for the speed of the laser beam?
- 70. A spaceship and its occupants have a total mass of 150,000 kg. The occupants would like to travel to a star that is 25 light-years away at a speed of 0.60c. To accelerate, the engine of the spaceship changes mass directly to energy. How much mass will be converted to energy to accelerate the spaceship to this speed? Assume the acceleration is rapid, so the speed for the entire trip can be taken to be $0.60c$, and ignore decrease in total mass for the calculation. How long will the trip take according to the astronauts on board?
- 71. Suppose a 12,500-kg spaceship left Earth at a speed of 0.99c. What is the spaceship's kinetic energy? Compare with the total U.S. annual energy consumption (about 10^{20} J).
- 72. A 42,000-kg spaceship is to travel to the vicinity of a star 6.0 light-years from Earth. Passengers on the ship want the (one-way) trip to take no more than 1.0 year. How much work must be done on the spaceship to bring it to the speed necessary for this trip?
- 73. A 1.68-kg mass oscillates on the end of a spring whose spring stiffness constant is $k = 48.7$ N/m. If this system is in a spaceship moving past Earth at 0.900c, what is its period of oscillation according to (a) observers on the ship, and (b) observers on Earth?
- 74. A pi meson of rest mass m_{π} decays at rest into a muon (rest mass m_u) and a neutrino of negligible or zero rest mass. Show that the kinetic energy of the muon is $KE_{\mu} = (m_{\pi} - m_{\mu})^2 c^2 / 2 m_{\pi}$.
- A: Yes. D: 0.36c. **B:** (a) 2.21 μ s; (b) 5.0 μ s. E: No. $C: (a) No; (b) yes.$ **F:** 0.030 c , same as classical, to an accuracy of better than 0.1%.

Electron microscopes produce images using electrons which have wave properties just as light does. Since the wavelength of electrons can be much smaller than that of visible light, much greater resolution and magnification can be obtained. A scanning electron microscope can produce images with a three-dimensional quality, as for these Giardia cells inside a human small intestine. Magnification is about $2000 \times$. Giardia is on the minds of backpackers (and others) because it has become too common in untreated water, even in the high mountains, and causes an unpleasant intestinal infection not easy to get rid of.

Early Quantum Theory and Models of the Atom

The second aspect of the revolution that shook the world of physics in the early part of the twentieth century (the first was Einstein's theory of relativity) was the quantum theory. Unlike the special theory of relativity, the revolution of quantum theory required almost three decades to unfold, and many scientists contributed to its development. It began in 1900 with Planck's quantum hypothesis, and culminated in the mid-1920s with the theory of quantum mechanics of Schrödinger and Heisenberg which has been so effective in explaining the structure of matter. The discovery of the electron in the 1890s, with which we begin this Chapter, might be said to mark the beginning of modern physics, and is a sort of precursor to the quantum theory.

-1 Discovery and Properties of the Electron

Toward the end of the nineteenth century, studies were being done on the discharge of electricity through rarefied gases. One apparatus, diagrammed in Fig. 27-1, consisted of a glass tube fitted with electrodes and evacuated so only a small amount of gas remained inside. When a very high voltage was applied to the electrodes, a dark space seemed to extend outward from the cathode (negative electrode) toward the opposite end of the tube; and that far end of the tube would glow. If one or more screens containing a small hole were inserted as shown, the glow was restricted to a tiny spot on the end of the tube. It seemed as though something being emitted by the cathode traveled across to the opposite end of the tube. These "somethings" were named cathode rays.

There was much discussion at the time about what these rays might be. Some scientists thought they might resemble light. But the observation that the bright spot at the end of the tube could be deflected to one side by an

FIGURE 27-1 Discharge tube. In some models, one of the screens is the anode (positive plate).

electric or magnetic field suggested that cathode rays could be charged particles; and the direction of the deflection was consistent with a negative charge. Furthermore, if the tube contained certain types of rarefied gas, the path of the cathode rays was made visible by a slight glow.

Estimates of the charge e of the (assumed) cathode-ray particles, as well as of their charge-to-mass ratio e/m , had been made by 1897. But in that year, J. J. Thomson (1856–1940) was able to measure e/m directly, using the apparatus shown in Fig. 27–2. Cathode rays are accelerated by a high voltage and then pass between a pair of parallel plates built into the tube. The voltage applied to the plates produces an electric field, and a pair of coils produces a magnetic field.

When only the electric field is present, say with the upper plate positive, the cathode rays are deflected upward as in path a in Fig. 27-2. If only a magnetic field exists, say inward, the rays are deflected downward along path c. These observations are just what is expected for a negatively charged particle. The magnitude of force on the rays due to the magnetic field is $F_{\text{mag}} = evB$, where *e* is the charge and *v* is the velocity of the cathode rays (Eq. 20-4). In the absence of an electric field, the rays are bent into a curved path, and applying Newton's second law $F = ma$ to a cathode ray gives

$$
evB = m\frac{v^2}{r},
$$

and thus

$$
\frac{e}{m} = \frac{v}{Br}
$$

The radius of curvature r can be measured and so can B . The velocity v can be found by applying an electric field in addition to the magnetic field. The electric field E is adjusted so that the cathode rays are undeflected and follow path b in Fig. 27–2. In this situation the upward force due to the electric field, $F_{el} = eE$, is balanced by the downward force due to the magnetic field, $F_{\text{mag}} = evB$. We equate the two forces, $eE = evB$, and find

$$
v=\frac{E}{B}.
$$

Combining this with the above equation we have

$$
\frac{e}{m} = \frac{E}{B^2 r}.
$$
\n(27)

The quantities on the right side can all be measured, and although e and m could not be determined separately, the ratio e/m could be determined. The accepted value today is $e/m = 1.76 \times 10^{11}$ C/kg. Cathode rays soon came to be called **electrons**.

The "discovery" of the electron, like many others in science, is not quite so obvious as discovering gold or oil. Should the discovery of the electron be credited to the person who first saw a glow in the tube? Or to the person who first called them cathode rays? Perhaps neither one, for they had no conception of the electron as we know it today. In fact, the credit for the discovery is generally given to Thomson, but not because he was the first to see the glow in the tube.

FIGURE 27-2 Cathode rays deflected by electric and magnetic fields.

-1) e/m measured

"Discovery" of the electron

Rather it is because he believed that this phenomenon was due to tiny negatively charged particles and made careful measurements on them. Furthermore he argued that these particles were constituents of atoms, and not ions or atoms themselves as many thought, and he developed an electron theory of matter. His view is close to what we accept today, and this is why Thomson is credited with the "discovery." Note, however, that neither he nor anyone else ever actually saw an electron itself. We discuss this briefly, for it illustrates the fact that discovery in science is not always a clear-cut matter. In fact some philosophers of science think the word "discovery" is often not appropriate, such as in this case.

Thomson believed that an electron was not an atom, but rather a constituent, or part, of an atom. Convincing evidence for this came soon with the determination of the charge and the mass of the cathode rays. Thomson's student J. S. Townsend made the first direct (but rough) measurements of e in 1897. But it was the more refined oil-drop experiment of Robert A. Millikan (1868–1953) that yielded a precise value for the charge on the electron and showed that charge comes in discrete amounts. In this experiment, tiny droplets of mineral oil carrying an electric charge were allowed to fall under gravity between two parallel plates, Fig. $27-3$. The electric field E between the plates was adjusted until the drop was suspended in midair. The downward pull of gravity on a drop of mass m_{dr} was $m_{dr}g$, and was just balanced by the upward force due to the electric field. Thus $qE = m_{\text{dr}}g$ so the charge q on a droplet was $q = m_{\text{dr}} g/E$. The mass of the droplet was determined by measuring its terminal velocity in the absence of the electric field. Often the droplet was charged negatively, but sometimes it was positive, suggesting that the droplet had acquired or lost electrons (by friction, leaving the atomizer). Millikan's painstaking observations and analysis presented convincing evidence that any charge was an integral multiple of a smallest charge, e, that was ascribed to the electron, and that the value of e was 1.6×10^{-19} C. (Today's value of e, as mentioned in Chapter 16, is $e = 1.602 \times 10^{-19}$ C.) This value of e, combined with the measurement of e/m , gives the mass of the electron to be $(1.6 \times 10^{-19} \text{ C})/(1.76 \times 10^{11} \text{ C/kg}) = 9.1 \times 10^{-31} \text{ kg}$. This mass is less than a thousandth the mass of the smallest atom, and thus confirmed the idea that the electron is only a part of an atom. The accepted value today for the mass of the electron is $m_e = 9.11 \times 10^{-31}$ kg. The experimental results that any charge seems to be an integral multiple of e means that electric charge is *quantized* (exists only in discrete amounts), as we discussed in Chapter 16.

27-2 Planck's Quantum Hypothesis; **Blackbody Radiation**

Blackbody Radiation

One of the observations that was unexplained at the end of the nineteenth century was the spectrum of light emitted by hot objects. We saw in Section 14-8 that all objects emit radiation whose total intensity is proportional to the fourth power of the Kelvin (absolute) temperature $(T⁴)$. At normal temperatures $(\approx 300 \text{ K})$, we are not aware of this electromagnetic radiation because of its low intensity. At higher temperatures, there is sufficient infrared radiation that we can feel heat if we are close to the object. At still higher temperatures (on the order of $1000 K$), objects actually glow, such as a red-hot electric stove burner or the element in a toaster. At temperatures above 2000 K, objects glow with a yellow or whitish color, such as white-hot iron and the filament of a lightbulb. The light emitted is of a continuous range of wavelengths or frequencies, and the spectrum is a plot of intensity vs. wavelength or frequency. As the temperature increases, the electromagnetic radiation emitted by objects not only increases in total intensity but is strongest at higher and higher frequencies.

Millikan oil-drop experiment

FIGURE 27-3 Millikan's oil-drop experiment.

FIGURE 27-4 Measured spectra of wavelengths and frequencies emitted by a blackbody at three different temperatures.

Blackbody radiation

The spectrum of light emitted by a hot dense object is shown in Fig. 27–4 for an idealized **blackbody**. A blackbody is a body that would absorb all the radiation falling on it (and so would appear black under reflection when illuminated from outside). The radiation such a blackbody would emit when hot and luminous, called blackbody radiation (though not necessarily black in color), is the easiest to deal with, and the radiation approximates that from many real objects. The 6000-K curve in Fig. 27-4, corresponding to the temperature of the surface of the Sun, peaks in the visible part of the spectrum. For lower temperatures, the total radiation drops considerably and the peak occurs at longer wavelengths (or lower frequencies). Hence the blue end of the visible spectrum (and the UV) is relatively weaker at lower temperatures. (This is why objects glow with a red color at around $1000 K$.) It is found experimentally that the wavelength at the peak of the spectrum, λ_{P} , is related to the Kelvin temperature T by

$$
\lambda_p T = 2.90 \times 10^{-3} \,\mathrm{m} \cdot \mathrm{K}.\tag{27-2}
$$

This is known as Wien's law.

EXAMPLE 27-1 The Sun's surface temperature. Estimate the temperature of the surface of our Sun, given that the Sun emits light whose peak intensity occurs in the visible spectrum at around 500 nm.

APPROACH We assume the Sun acts as a blackbody, and use $\lambda_{P} = 500$ nm in Wien's law (Eq. $27-2$).

SOLUTION Wien's law gives

$$
T = \frac{2.90 \times 10^{-3} \,\mathrm{m} \cdot \mathrm{K}}{\lambda_{\mathrm{P}}} = \frac{2.90 \times 10^{-3} \,\mathrm{m} \cdot \mathrm{K}}{500 \times 10^{-9} \,\mathrm{m}} \approx 6000 \,\mathrm{K}.
$$

EXAMPLE 27-2 Star color. Suppose a star has a surface temperature of 32,500 K. What color would this star appear?

APPROACH We assume the star emits radiation as a blackbody, and solve for $\lambda_{\rm P}$ in Wien's law, Eq. 27–2.

SOLUTION From Wien's law we have

$$
\lambda_{\rm P} = \frac{2.90 \times 10^{-3} \,\mathrm{m} \cdot \mathrm{K}}{T} = \frac{2.90 \times 10^{-3} \,\mathrm{m} \cdot \mathrm{K}}{3.25 \times 10^{4} \,\mathrm{K}} = 89.2 \,\mathrm{nm}.
$$

The peak is in the UV range of the spectrum, and will be way to the left in Fig. 27–4. In the visible region, the curve will be descending, so the shortest visible wavelengths will be strongest. Hence the star will appear bluish (or blue-white).

NOTE This example helps us to understand why stars have different colors (reddish for the coolest stars, orangish, yellow, white, bluish for "hotter" stars.)

EXERCISE A What is the color of an object at 4000 K?

Planck's Quantum Hypothesis

In the year 1900, Max Planck (1858–1947) proposed a theory that was able to reproduce the graphs of Fig. 27-4. His theory, still accepted today, made a new and radical assumption: that the energy of the oscillations of atoms within molecules cannot have just any value; instead each has energy which is a multiple of a minimum value related to the frequency of oscillation by

$$
E = hf
$$
.

Here h is a new constant, now called **Planck's constant**, whose value was estimated by Planck by fitting his formula for the blackbody radiation curve to experiment. The value accepted today is

$$
h = 6.626 \times 10^{-34}
$$
 J·s.

Planck's assumption suggests that the energy of any molecular vibration could be only some whole number multiple of hf :

$$
E = nhf, \qquad n = 1, 2, 3, \cdots.
$$
 (27-3)

where n is called a **quantum number** ("quantum" means "discrete amount" as opposed to "continuous"). This idea is often called Planck's quantum hypothesis, although little attention was brought to this point at the time. In fact, it appears that Planck considered it more as a mathematical device to get the "right answer" rather than as a discovery comparable to those of Newton. Planck himself continued to seek a classical explanation for the introduction of h . The recognition that this was an important and radical innovation did not come until later, after about 1905 when others, particularly Einstein, entered the field.

The quantum hypothesis, Eq. $27-3$, states that the energy of an oscillator can be $E = hf$, or $2hf$, or $3hf$, and so on, but there cannot be vibrations with energies between these values. That is, energy would not be a continuous quantity as had been believed for centuries; rather it is quantized—it exists only in discrete amounts. The smallest amount of energy possible (hf) is called the quantum of energy. Recall from Chapter 11 that the energy of an oscillation is proportional to the amplitude squared. Thus another way of expressing the quantum hypothesis is that not just any amplitude of vibration is possible. The possible values for the amplitude are related to the frequency f .

A simple analogy may help. A stringed instrument such as a violin or guitar can be played over a continuous range of frequencies by moving your finger along the string. A flute or piano, on the other hand, is "quantized" in the sense that only certain frequencies (notes) can be played. Or compare a ramp, on which a box can be placed at any height, to a flight of stairs on which the box can have only certain discrete amounts of potential energy, as shown in Fig. 27–5.

27-3 Photon Theory of Light and the **Photoelectric Effect**

In 1905, the same year that he introduced the special theory of relativity, Einstein made a bold extension of the quantum idea by proposing a new theory of light. Planck's work had suggested that the vibrational energy of molecules in a radiating object is quantized with energy $E = nhf$, where *n* is an integer and f is the frequency of molecular vibration. Einstein argued that when light is emitted by a molecular oscillator, the molecule's vibrational energy of nhf must decrease by an amount hf (or by $2hf$, etc.) to another integer times hf , such as $(n - 1)hf$. Then to conserve energy, the light ought to be emitted in packets, or quanta, each with an energy

 $E = hf$,

 $(27-4)$

where f is here the frequency of the emitted light.

Planck's quantum hypothesis

FIGURE 27-5 Ramp versus stair analogy. (a) On a ramp, a box can have continuous values of potential energy. (b) But on stairs, the box can have only discrete (quantized) values of energy.

Again h is Planck's constant. Since all light ultimately comes from a radiating source, this suggests that perhaps light is transmitted as tiny particles, or **photons**, as they are now called, in addition to the waves predicted by Maxwell's electromagnetic theory. The photon theory of light was also a radical departure from classical ideas. Einstein proposed a test of the quantum theory of light: quantitative measurements on the photoelectric effect.

When light shines on a metal surface, electrons are found to be emitted from the surface. This effect is called the **photoelectric effect** and it occurs in many materials, but is most easily observed with metals. It can be observed using the apparatus shown in Fig. 27-6. A metal plate P and a smaller electrode C are placed inside an evacuated glass tube, called a photocell. The two electrodes are connected to an ammeter and a source of emf, as shown. When the photocell is in the dark, the ammeter reads zero. But when light of sufficiently high frequency illuminates the plate, the ammeter indicates a current flowing in the circuit. We explain completion of the circuit by imagining that electrons, ejected by the impinging radiation, flow across the tube from the plate to the "collector" C as indicated in Fig. 27-6.

That electrons should be emitted when light shines on a metal is consistent with the electromagnetic (EM) wave theory of light: the electric field of an EM wave could exert a force on electrons in the metal and eject some of them. Einstein pointed out, however, that the wave theory and the photon theory of light give very different predictions on the details of the photoelectric effect. For example, one thing that can be measured with the apparatus of Fig. 27–6 is the maximum kinetic energy (KE_{max}) of the emitted electrons. This can be done by using a variable voltage source and reversing the terminals so that electrode C is negative and P is positive. The electrons emitted from P will be repelled by the negative electrode, but if this reverse voltage is small enough, the fastest electrons will still reach C and there will be a current in the circuit. If the reversed voltage is increased, a point is reached where the current reaches zero-no electrons have sufficient kinetic energy to reach C. This is called the stopping potential, or stopping voltage, V_0 , and from its measurement, KE_{max} can be determined using conservation of energy (loss of $KE = gain in PE$):

 $KE_{\text{max}} = eV_0$.

Now let us examine the details of the photoelectric effect from the point of view of the wave theory versus Einstein's particle theory.

Photons

Photoelectric effect

First the wave theory, assuming monochromatic light. The two important properties of a light wave are its intensity and its frequency (or wavelength). When these two quantities are varied, the wave theory makes the following predictions:

1. If the light intensity is increased, the number of electrons ejected and their maximum kinetic energy should be increased because the higher intensity means a greater electric field amplitude, and the greater electric field

2. The frequency of the light should not affect the kinetic energy of the

ejected electrons. Only the intensity should affect KE_{max} .

should eject electrons with higher speed.

Wave

predictions

theory

One photon collides with one electron, ejecting it

The photon theory makes completely different predictions. First we note that in a monochromatic beam, all photons have the same energy $(= hf)$. Increasing the intensity of the light beam means increasing the number of photons in the beam, but does not affect the energy of each photon as long as the frequency is not changed. According to Einstein's theory, an electron is ejected from the metal by a collision with a single photon. In the process, all the photon energy is transferred to the electron and the photon ceases to exist. Since electrons are held in the metal by attractive forces, some minimum energy W_0 is required just to get an electron out through the surface. W_0 is called the work function, and is a few electron volts $(1 \text{ eV} = 1.6 \times 10^{-19} \text{ J})$ for most metals. If the frequency f of the incoming light is so low that hf is less than W_0 , then the photons will not have enough energy to eject any electrons at all. If $hf > W_0$, then electrons will be ejected and energy will be conserved in the process. That is, the input energy (of the photon), hf , will equal the outgoing kinetic energy KE of the electron plus the energy required to get it out of the metal, W:

$$
hf = \kappa E + W.
$$
 (27-5a)

The least tightly held electrons will be emitted with the most kinetic energy (κ E_{max}), in which case W in this equation becomes the work function W_0 , and KE becomes KE_{max} :

$$
hf = \kappa E_{\text{max}} + W_0.
$$
 [least bound electrons] (27-5b)

Many electrons will require more energy than the bare minimum (W_0) to get out of the metal, and thus the kinetic energy of such electrons will be less than the maximum.

From these considerations, the photon theory makes the following predictions:

Photon

theory

- 1. An increase in intensity of the light beam means more photons are incident, so more electrons will be ejected; but since the energy of each photon is not changed, the maximum kinetic energy of electrons is not changed by an increase in intensity.
- 2. If the frequency of the light is increased, the maximum kinetic energy of the electrons increases linearly, according to Eq. 27-5b. That is,

$$
KE_{\text{max}} = hf - W_0.
$$

This relationship is plotted in Fig. 27-7.

3. If the frequency f is less than the "cutoff" frequency f_0 , where $hf_0 = W_0$, no electrons will be ejected, no matter how great the intensity of the light.

These predictions of the photon theory are clearly very different from the predictions of the wave theory. In 1913–1914, careful experiments were carried out by R. A. Millikan. The results were fully in agreement with Einstein's photon theory.

One other aspect of the photoelectric effect also confirmed the photon theory. If extremely low light intensity is used, the wave theory predicts a time delay before electron emission so that an electron can absorb enough energy to exceed the work function. The photon theory predicts no such delay—it only takes one photon (if its frequency is high enough) to eject an

predictions

FIGURE 27-7 Photoelectric effect: the maximum kinetic energy of ejected electrons increases linearly with the frequency of incident light. No electrons are emitted if $f < f_0$.

760 CHAPTER 27 Early Quantum Theory and Models of the Atom

electron—and experiments showed no delay. This too confirmed Einstein's photon theory.

EXAMPLE 27-3 Photon energy. Calculate the energy of a photon of blue light, $\lambda = 450$ nm in air (or vacuum).

APPROACH The photon has energy $E = hf$ (Eq. 27-4) where $f = c/\lambda$ $(Eq. 22-4).$

SOLUTION Since $f = c/\lambda$, we have

$$
E = hf = \frac{hc}{\lambda} = \frac{(6.63 \times 10^{-34} \,\text{J} \cdot \text{s})(3.0 \times 10^8 \,\text{m/s})}{(4.5 \times 10^{-7} \,\text{m})} = 4.4 \times 10^{-19} \,\text{J},
$$

or $(4.4 \times 10^{-19} \text{ J})/(1.60 \times 10^{-19} \text{ J/eV}) = 2.8 \text{ eV}$. (See definition of eV in Section 17-4, $1 \text{ eV} = 1.60 \times 10^{-19} \text{ J.}$

EXERCISE B A beam contains infrared light of a single wavelength, 1000 nm, and monochromatic UV at 100 nm, both of the same intensity. Are there more 100-nm photons or more 1000-nm photons?

EXAMPLE 27-4 Photoelectron speed and energy. What is the kinetic energy and the speed of an electron ejected from a sodium surface whose work function is $W_0 = 2.28$ eV when illuminated by light of wavelength (a) 410 nm, (b) 550 nm?

APPROACH We first find the energy of the photons $(E = hf = hc/\lambda)$. If the energy is greater than W_0 , then electrons will be ejected with varying amounts of KE, with a maximum of $KE_{max} = hf - W_0$.

SOLUTION (a) For $\lambda = 410$ nm,

$$
hf = \frac{hc}{\lambda} = 4.85 \times 10^{-19} \text{ J}
$$
 or 3.03 eV.

The maximum kinetic energy an electron can have is given by Eq. 27-5b, $KE_{\text{max}} = 3.03 \text{ eV} - 2.28 \text{ eV} = 0.75 \text{ eV}$, or $(0.75 \text{ eV})(1.60 \times 10^{-19} \text{ J/eV}) =$ 1.2×10^{-19} J. Since $KE = \frac{1}{2}mv^2$ where $m = 9.1 \times 10^{-31}$ kg,

$$
v_{\text{max}} = \sqrt{\frac{2\text{KE}}{m}} = 5.1 \times 10^5 \text{ m/s}.
$$

Most ejected electrons will have less KE and less speed than these maximum values.

(b) For $\lambda = 550$ nm, $hf = hc/\lambda = 3.61 \times 10^{-19}$ J = 2.26 eV. Since this photon energy is less than the work function, no electrons are ejected.

NOTE In (a) we used the nonrelativistic equation for kinetic energy. If v had turned out to be more than about 0.1c, our calculation would have been inaccurate by more than a percent or so, and we would probably prefer to redo it using the relativistic form $(Eq. 26-6)$.

EXERCISE C Determine the lowest frequency and the longest wavelength needed to emit electrons from sodium.

It is easy to show (see Problem 28) just by converting units that the energy of a photon in electron volts, when given the wavelength λ in nm, is

$$
E (eV) = \frac{1.240 \times 10^{8} \text{ eV} \cdot \text{nm}}{\lambda (\text{nm})}.
$$
 [photon energy in eV]

FIGURE 27-8 Optical sound track on movie film. In the projector, light from a small source (different from that for the picture) passes through the sound track on the moving film. The light and dark areas on the sound track vary the intensity of the transmitted light which reaches the photocell, whose current output is then a replica of the original sound. This output is amplified and sent to the loudspeakers. High-quality projectors can show movies containing several parallel sound tracks to go to different speakers around the theater.

Applications of the Photoelectric Effect

The photoelectric effect, besides playing an important historical role in confirming the photon theory of light, also has many practical applications. Burglar alarms and automatic door openers often make use of the photocell circuit of Fig. 27–6. When a person interrupts the beam of light, the sudden drop in current in the circuit activates a switch—often a solenoid—which operates a bell or opens the door. UV or IR light is sometimes used in burglar alarms because of its invisibility. Many smoke detectors use the photoelectric effect to detect tiny amounts of smoke that interrupt the flow of light and so alter the electric current. Photographic light meters use this circuit as well. Photocells are used in many other devices, such as absorption spectrophotometers, to measure light intensity. One type of film sound track is a variably shaded narrow section at the side of the film. Light passing through the film is thus "modulated," and the output electrical signal of the photocell detector follows the frequencies on the sound track. See Fig. 27–8. For many applications today, the vacuum-tube photocell of Fig. 27-6 has been replaced by a semiconductor device known as a **photodiode** (Section 29–8). In these semiconductors, the absorption of a photon liberates a bound electron, which changes the conductivity of the material, so the current through a photodiode is altered.

4 Energy, Mass, and Momentum of a Photon

We have just seen $(Eq, 27-4)$ that the total energy of a single photon is given by $E = hf$. Because a photon always travels at the speed of light, it is truly a relativistic particle. Thus we must use relativistic formulas for dealing with its mass, energy, and momentum. The momentum of any particle of rest mass m_0 is given by $p = m_0 v / \sqrt{1 - v^2/c^2}$. Since $v = c$ for a photon, the denominator is zero. To avoid having an infinite momentum, we conclude that the photon's rest mass must be zero: $m_0 = 0$. This makes sense too because a photon can never be at rest (it goes at the speed of light). A photon's kinetic energy is its total energy:

$$
KE = E = hf.
$$
 [photon]

The momentum of a photon can be obtained from the relativistic formula (Eq. 26–10) $E^2 = p^2c^2 + m_0^2c^4$ where we set $m_0 = 0$ so $E^2 = p^2c^2$ or

> $p = \frac{E}{a}$. [photon]

Since $E = hf$ for a photon, its momentum is related to its wavelength by

$$
p = \frac{E}{c} = \frac{hf}{c} = \frac{h}{\lambda}.
$$
\n(27-6)

EXAMPLE 27-5 ESTIMATE Photons from a lightbulb. Estimate how many visible light photons a 100-W lightbulb emits per second. Assume the bulb has a typical efficiency of about 3% (that is, 97% of the energy goes to heat).

APPROACH Let's assume an average wavelength in the middle of the visible spectrum, $\lambda \approx 500$ nm. The energy of each photon is $E = hf = hc/\lambda$. Only 3% of the 100-W power is emitted as light, or $3 W = 3 J/s$. The number of photons emitted per second equals the light output of 3 J per second divided by the energy of each photon.

SOLUTION The energy emitted in one second $(= 3 J)$ is $E = Nhf$ where N is the number of photons emitted per second and $f = c/\lambda$. Hence

$$
N = \frac{E}{hf} = \frac{E\lambda}{hc} = \frac{(3 \text{ J})(500 \times 10^{-9} \text{ m})}{(6.63 \times 10^{-34} \text{ J} \cdot \text{s})(3.0 \times 10^8 \text{ m/s})} \approx 8 \times 10^{18}
$$

per second, or almost 10^{19} photons emitted per second, an enormous number.

 \bullet CAUTION Momentum of photon is not mv **EXAMPLE 27-6** Photon momentum and force. Suppose the 10^{19} photons emitted per second from the 100-W lightbulb in Example 27–5 were all focused onto a piece of black paper and absorbed. (a) Calculate the momentum of one photon and (b) estimate the force all these photons could exert on the paper.

APPROACH Each photon's momentum is obtained from Eq. 27–6, $p = h/\lambda$. Next, each absorbed photon's momentum changes from $p = h/\lambda$ to zero. We use Newton's second law, $F = \Delta p / \Delta t$, to get the force.

SOLUTION (*a*) Each photon has a momentum

$$
p = \frac{h}{\lambda} = \frac{6.63 \times 10^{-34} \,\text{J} \cdot \text{s}}{500 \times 10^{-9} \,\text{m}} = 1.3 \times 10^{-27} \,\text{kg} \cdot \text{m/s}.
$$

(b) Using Newton's second law for $N = 10^{19}$ photons (Example 27–5) whose momentum changes from h/λ to 0, we obtain

$$
F = \frac{\Delta p}{\Delta t} = \frac{Nh/\lambda - 0}{1 \text{ s}} = N \frac{h}{\lambda} \approx (10^{19} \text{ s}^{-1})(10^{-27} \text{ kg} \cdot \text{m/s}) \approx 10^{-8} \text{ N}.
$$

This is a pretty tiny force, but we can see that a very strong light source could exert a measurable force, and near the Sun or a star the force due to photons in electromagnetic radiation could be considerable.

EXAMPLE 27-7 Photosynthesis. In *photosynthesis*, pigments such as chlorophyll in plants capture the energy of sunlight to change $CO₂$ to useful carbohydrate. About nine photons are needed to transform one molecule of CO₂ to carbohydrate and O₂. Assuming light of wavelength $\lambda = 670$ nm (chlorophyll absorbs most strongly in the range 650 nm to 700 nm), how efficient is the photosynthetic process? The reverse chemical reaction releases an energy of 4.9 eV/molecule of $CO₂$.

APPROACH The efficiency is the minimum energy required (4.9 eV) divided by the actual energy absorbed, nine times the energy (hf) of one photon.

SOLUTION The energy of nine photons, each of energy $hf = hc/\lambda$ is $(9)(6.63 \times 10^{-34} \text{ J} \cdot \text{s})(3.0 \times 10^8 \text{ m/s})/(6.7 \times 10^{-7} \text{ m}) = 2.7 \times 10^{-18} \text{ J}$ or 17 eV. Thus the process is $(4.9 \text{ eV}/17 \text{ eV}) = 29\%$ efficient.

27-5 Compton Effect

Besides the photoelectric effect, a number of other experiments were carried out in the early twentieth century which also supported the photon theory. One of these was the **Compton effect** (1923) named after its discoverer, A. H. Compton (1892-1962). Compton scattered short-wavelength light (actually X-rays) from various materials. He found that the scattered light had a slightly longer wavelength than did the incident light, and therefore a slightly lower frequency indicating a loss of energy. He explained this result on the basis of the photon theory as incident photons colliding with electrons of the material, Fig. 27–9. Using Eq. 27–6 for momentum of a photon, Compton applied the laws of conservation of momentum and energy to the collision of Fig. 27–9 and derived the following equation for the wavelength of the scattered photons:

$$
\lambda' = \lambda + \frac{h}{m_0 c} \left(1 - \cos \phi \right),\tag{27-7}
$$

where m_0 is the rest mass of the electron. (The quantity h/m_0c , which has the dimensions of length, is called the **Compton wavelength** of the electron.) We see that the predicted wavelength of scattered photons depends on the angle ϕ at which they are detected. Compton's measurements of 1923 were consistent with this formula. The wave theory of light predicts no such shift: an incoming EM wave of frequency f should set electrons into oscillation at frequency f ; and such oscillating electrons would reemit EM waves of this same frequency f (Section 22–2), which would not change with angle (ϕ) . Hence the Compton effect adds to the firm experimental foundation for the photon theory of light.

PHYSICS APPLIED Photosynthesis

FIGURE 27-9 The Compton effect. A single photon of wavelength λ strikes an electron in some material, knocking it out of its atom. The scattered photon has less energy (since some is given to the electron) and hence has a longer wavelength λ' . Experiments found scattered X-rays of just the wavelengths predicted by conservation of energy and momentum using the photon model.

EXERCISE D When a photon scatters off an electron by the Compton effect, which of the following increase: its energy, frequency, wavelength?

EXAMPLE 27-8 X-ray scattering. X-rays of wavelength 0.140 nm are scattered from a very thin slice of carbon. What will be the wavelengths of X-rays scattered at (*a*) 0° , (*b*) 90° , (*c*) 180° ?

APPROACH This is an example of the Compton effect, and we use Eq. 27-7 to find the wavelengths.

SOLUTION (a) For $\phi = 0^{\circ}$, $\cos \phi = 1$ and $1 - \cos \phi = 0$. Then Eq. 27-7 gives $\lambda' = \lambda = 0.140$ nm. This makes sense since for $\phi = 0^{\circ}$, there really isn't any collision as the photon goes straight through without interacting. (b) For $\phi = 90^{\circ}$, cos $\phi = 0$, and $1 - \cos \phi = 1$. So

$$
\lambda' = \lambda + \frac{h}{m_0 c} = 0.140 \text{ nm} + \frac{6.63 \times 10^{-34} \text{ J} \cdot \text{s}}{(9.11 \times 10^{-31} \text{ kg})(3.00 \times 10^8 \text{ m/s})}
$$

= 0.140 nm + 2.4 × 10⁻¹² m = 0.142 nm;

that is, the wavelength is longer by one Compton wavelength $(= 0.0024 \text{ nm}$ for an electron).

(c) For $\phi = 180^{\circ}$, which means the photon is scattered backward, returning in the direction from which it came (a direct "head-on" collision), $\cos \phi = -1$, and $1 - \cos \phi = 2$. So

$$
\lambda' = \lambda + 2 \frac{h}{m_0 c} = 0.140 \text{ nm} + 2(0.0024 \text{ nm}) = 0.145 \text{ nm}.
$$

NOTE The maximum shift in wavelength occurs for backward scattering, and it is twice the Compton wavelength.

 \overline{X} PHYSICS APPLIED Measuring bone density

The Compton effect has been used to diagnose bone disease such as osteoporosis. Gamma rays, which are photons of even shorter wavelength than X-rays, coming from a radioactive source are scattered off bone material. The total intensity of the scattered radiation is proportional to the density of electrons, which is in turn proportional to the bone density. Changes in the density of bone can indicate the onset of osteoporosis.

-6 Photon Interactions; Pair Production

When a photon passes through matter, it interacts with the atoms and electrons. There are four important types of interactions that a photon can undergo:

1. The *photoelectric effect*: a photon may knock an electron out of an atom

Photon

interactions

FIGURE 27-10 Pair production: a photon disappears and produces an electron and a positron.

and in the process itself disappear. 2. The photon may knock an atomic electron to a higher energy state in the atom if its energy is not sufficient to knock the electron out altogether. In

- this process the photon also disappears, and all its energy is given to the atom. Such an atom is then said to be in an excited state, and we shall discuss it more later.
- 3. The photon can be scattered from an electron (or a nucleus) and in the process lose some energy; this is the *Compton effect* (Section 27–5). But notice that the photon is not slowed down. It still travels with speed c , but its frequency will be lower because it has lost some energy.
- 4. Pair production: A photon can actually create matter, such as the production of an electron and a positron, Fig. $27-10$. (A positron has the same mass as an electron, but the opposite charge, $+e$.)

In process 4, pair production, the photon disappears in the process of creating the electron-positron pair. This is an example of rest mass being created from pure energy, and it occurs in accord with Einstein's equation $E = mc^2$.

764 CHAPTER 27 Early Quantum Theory and Models of the Atom

Notice that a photon cannot create an electron alone since electric charge would not then be conserved. The inverse of pair production also occurs: if an electron collides with a positron, the two **annihilate** each other and their energy, including their mass, appears as electromagnetic energy of photons. Because of this process, positrons usually do not last long in nature.

Electron-positron annihilation is the basis for the type of medical imaging known as PET, as discussed in Section 31-8.

EXAMPLE 27-9 Pair production. (a) What is the minimum energy of a photon that can produce an electron-positron pair? (b) What is this photon's wavelength?

APPROACH The minimum photon energy E equals the rest energy (m_0c^2) of the two particles created, via Einstein's famous equation $E = m_0 c^2$ (Eq. 26–8). There is no energy left over, so the particles produced will have zero KE. The wavelength is $\lambda = c/f$ where $E = hf$ for the original photon.

SOLUTION (a) Because $E = m_0 c^2$, and the mass created is equal to two electron rest masses, the photon must have energy

 $E = 2(9.11 \times 10^{-31} \text{ kg})(3.0 \times 10^8 \text{ m/s})^2 = 1.64 \times 10^{-13} \text{ J} = 1.02 \text{ MeV}$

 $(1 \text{ MeV} = 10^6 \text{ eV} = 1.60 \times 10^{-13} \text{ J})$. A photon with less energy cannot undergo pair production.

(b) Since $E = hf = hc/\lambda$, the wavelength of a 1.02-MeV photon is

$$
\lambda = \frac{hc}{E} = \frac{(6.63 \times 10^{-34} \,\text{J} \cdot \text{s})(3.0 \times 10^8 \,\text{m/s})}{(1.64 \times 10^{-13} \,\text{J})} = 1.2 \times 10^{-12} \,\text{m},
$$

which is 0.0012 nm. Such photons are in the gamma-ray (or very short X-ray) region of the electromagnetic spectrum (Fig. $22-8$).

NOTE Photons of higher energy (shorter wavelength) can also create an electron-positron pair, with the excess energy becoming kinetic energy of the particles.

Pair production cannot occur in empty space, for momentum could not be conserved. In Example $27-9$, for instance, energy is conserved, but only enough energy was provided to create the electron-positron pair at rest and thus with no momentum to carry away the initial momentum of the photon. Indeed, it can be shown that at any energy, an additional massive object, such as an atomic nucleus, must take part in the interaction to carry off some of the momentum.

27-7 Wave-Particle Duality; the Principle of Complementarity

The photoelectric effect, the Compton effect, and other experiments have placed the particle theory of light on a firm experimental basis. But what about the classic experiments of Young and others (Chapter 24) on interference and diffraction which showed that the wave theory of light also rests on a firm experimental basis?

We seem to be in a dilemma. Some experiments indicate that light behaves like a wave; others indicate that it behaves like a stream of particles. These two theories seem to be incompatible, but both have been shown to have validity. Physicists finally came to the conclusion that this duality of light must be accepted as a fact of life. It is referred to as the **wave-particle duality**. Apparently, light is a more complex phenomenon than just a simple wave or a simple beam of particles.

Minimum energy to produce e^+e^- pair is 1.02 MeV

Wave-particle duality

FIGURE 27-11 Niels Bohr (right), walking with Enrico Fermi along the Appian Way outside Rome. This photo shows one important way physics is done.

CAUTION

Not correct to say light is a wave and/or a particle. Light can act like a wave or like a particle

To clarify the situation, the great Danish physicist Niels Bohr (1885–1962, Fig. 27-11) proposed his famous principle of complementarity. It states that to understand an experiment, sometimes we find an explanation using wave theory and sometimes using particle theory. Yet we must be aware of both the wave and particle aspects of light if we are to have a full understanding of light. Therefore these two aspects of light complement one another.

It is not easy to "visualize" this duality. We cannot readily picture a combination of wave and particle. Instead, we must recognize that the two aspects of light are different "faces" that light shows to experimenters.

Part of the difficulty stems from how we think. Visual pictures (or models) in our minds are based on what we see in the everyday world. We apply the concepts of waves and particles to light because in the macroscopic world we see that energy is transferred from place to place by these two methods. We cannot see directly whether light is a wave or particle-so we do indirect experiments. To explain the experiments, we apply the models of waves or of particles to the nature of light. But these are abstractions of the human mind. When we try to conceive of what light really "is," we insist on a visual picture. Yet there is no reason why light should conform to these models (or visual images) taken from the macroscopic world. The "true" nature of light—if that means anything—is not possible to visualize. The best we can do is recognize that our knowledge is limited to the indirect experiments, and that in terms of everyday language and images, light reveals both wave and particle properties.

It is worth noting that Einstein's equation $E = hf$ itself links the particle and wave properties of a light beam. In this equation, E refers to the energy of a particle; and on the other side of the equation, we have the frequency f of the corresponding wave.

8 Wave Nature of Matter

In 1923, Louis de Broglie (1892-1987) extended the idea of the wave-particle duality. He much appreciated the symmetry in nature, and argued that if light sometimes behaves like a wave and sometimes like a particle, then perhaps those things in nature thought to be particles-such as electrons and other material objects—might also have wave properties. De Broglie proposed that the wavelength of a material particle would be related to its momentum in the same way as for a photon, Eq. 27–6, $p = h/\lambda$. That is, for a particle having linear momentum $p = mv$, the wavelength λ is given by

de Broglie wavelength

$$
\lambda = \frac{h}{p},\tag{27-8}
$$

and is valid classically ($p = m_0 v$ for $v \ll c$) and relativistically ($p = \gamma m_0 v$ = $m_0 v / \sqrt{1 - v^2/c^2}$). This is sometimes called the **de Broglie wavelength** of a particle.

EXAMPLE 27-10 Wavelength of a ball. Calculate the de Broglie wavelength of a 0.20-kg ball moving with a speed of 15 m/s .

APPROACH We simply use Eq. $27-8$.

SOLUTION
$$
\lambda = \frac{h}{p} = \frac{h}{mv} = \frac{(6.6 \times 10^{-34} \text{ J} \cdot \text{s})}{(0.20 \text{ kg})(15 \text{ m/s})} = 2.2 \times 10^{-34} \text{ m}.
$$

The wavelength of Example 27–10 is an unimaginably small wavelength. Even if the speed were extremely small, say 10^{-4} m/s, the wavelength would be about 10^{-29} m. Indeed, the wavelength of any ordinary object is much too small to be measured and detected. The problem is that the properties of waves, such as
interference and diffraction, are significant only when the size of objects or slits is not much larger than the wavelength. And there are no known objects or slits to diffract waves only 10^{-30} m long, so the wave properties of ordinary objects go undetected.

But tiny elementary particles, such as electrons, are another matter. Since the mass m appears in the denominator of Eq. 27–8, a very small mass should have a much larger wavelength.

EXAMPLE 27-11 Wavelength of an electron. Determine the wavelength of an electron that has been accelerated through a potential difference of 100 V.

APPROACH If the kinetic energy is much less than the rest energy, we can use classical $KE = \frac{1}{2}mv^2$ (see end of Section 26–9). For an electron, $m_0c^2 = 0.511 \text{ MeV}$. We then apply conservation of energy: the KE acquired by the electron equals its loss in PE. After solving for v, we use Eq. $27-8$ to find the de Broglie wavelength.

SOLUTION The gain in kinetic energy will equal the loss in potential energy $(\Delta PE = eV - 0)$: $KE = eV$, so $KE = 100$ eV. The ratio KE/m_0c^2 $100 \text{ eV}/(0.511 \times 10^6 \text{ eV}) \approx 10^{-4}$, so relativity is not needed. Thus

$$
\frac{1}{2}mv^2 = eV
$$

and

$$
v = \sqrt{\frac{2 \, eV}{m}} = \sqrt{\frac{(2)(1.6 \times 10^{-19} \, \text{C})(100 \, \text{V})}{(9.1 \times 10^{-31} \, \text{kg})}} = 5.9 \times 10^6 \, \text{m/s}.
$$

Then

$$
\lambda = \frac{h}{mv} = \frac{(6.63 \times 10^{-34} \,\text{J} \cdot \text{s})}{(9.1 \times 10^{-31} \,\text{kg})(5.9 \times 10^6 \,\text{m/s})} = 1.2 \times 10^{-10} \,\text{m},
$$

or 0.12 nm.

EXERCISE E As a particle travels faster, does its de Broglie wavelength decrease, increase, or remain the same?

From Example 27-11, we see that electrons can have wavelengths on the order of 10^{-10} m, and even smaller. Although small, this wavelength can be detected: the spacing of atoms in a crystal is on the order of 10^{-10} m and the orderly array of atoms in a crystal could be used as a type of diffraction grating, as was done earlier for X-rays (see Section 25-11). C. J. Davisson and L. H. Germer performed the crucial experiment; they scattered electrons from the surface of a metal crystal and, in early 1927, observed that the electrons were scattered into a pattern of regular peaks. When they interpreted these peaks as a diffraction pattern, the wavelength of the diffracted electron wave was found to be just that predicted by de Broglie, Eq. 27–8. In the same year, G. P. Thomson (son of J. J. Thomson) used a different experimental arrangement and also detected diffraction of electrons. (See Fig. 27-12. Compare it to X-ray diffraction, Section 25-11.) Later experiments showed that protons, neutrons, and other particles also have wave properties.

Thus the wave-particle duality applies to material objects as well as to light. The principle of complementarity applies to matter as well. That is, we must be aware of both the particle and wave aspects in order to have an understanding of matter, including electrons. But again we must recognize that a visual picture of a "wave-particle" is not possible.

FIGURE 27-12 Diffraction pattern of electrons scattered from aluminum foil, as recorded on film.

Wave-particle duality and complementarity apply to matter as well as light

What Is an Electron?

We might ask ourselves: "What is an electron?" The early experiments of J. J. Thomson (Section 27–1) indicated a glow in a tube, and that glow moved when a magnetic field was applied. The results of these and other experiments were best interpreted as being caused by tiny negatively charged particles which we now call electrons. No one, however, has actually seen an electron directly. The drawings we sometimes make of electrons as tiny spheres with a negative charge on them are merely convenient pictures (now recognized to be inaccurate). Again we must rely on experimental results, some of which are best interpreted using the particle model and others using the wave model. These models are mere pictures that we use to extrapolate from the macroscopic world to the tiny microscopic world of the atom. And there is no reason to expect that these models somehow reflect the reality of an electron. We thus use a wave or a particle model (whichever works best in a situation) so that we can talk about what is happening. But we should not be led to believe that an electron is a wave or a particle. Instead we could say that an electron is the set of its properties that we can measure. Bertrand Russell said it well when he wrote that an electron is "a logical construction."

27-9 Electron Microscopes

PHYSICS APPLIED Electron microscope

FIGURE 27-13 Transmission electron microscope. The magneticfield coils are designed to be "magnetic lenses," which bend the electron paths and bring them to a focus, as shown.

Image (on screen, film, or semiconductor detector)

The idea that electrons have wave properties led to the development of the electron microscope, which can produce images of much greater magnification than does a light microscope. Figures $27-13$ and $27-14$ are diagrams of two types, developed around the middle of the twentieth century: the **transmission** electron microscope, which produces a two-dimensional image, and the scanning electron microscope (SEM), which produces images with a three-dimensional quality. In both types, the objective and eyepiece lenses are actually magnetic fields that exert forces on the electrons to bring them to a focus. The fields are produced by carefully designed current-carrying coils of wire. Photographs using each type are shown in Fig. $27-15$.

As discussed in Sections 25-7 and 25-8, the maximum resolution of details on an object is about the size of the wavelength of the radiation used to view it. Electrons accelerated by voltages on the order of $10⁵$ V have wavelengths on the order of 0.004 nm. The maximum resolution obtainable would be on this order, but in practice, aberrations in the magnetic lenses limit the resolution in transmission electron microscopes to at best about 0.1 to 0.5 nm. This is still $10³$ times finer than that attainable with a visible-light microscope, and corresponds to a useful magnification of about a million. Such magnifications are difficult to attain, and more common magnifications are $10⁴$ to $10⁵$. The maximum resolution attainable with a scanning electron microscope is somewhat less, typically 5 to 10 nm although new high-resolution SEMs approach 1 nm.

FIGURE 27-15 Electron micrographs (in false color) of viruses attacking a cell of the bacterium *Escherichia coli:* (a) transmission electron micrograph (\approx 50,000 \times); (b) scanning electron micrograph (\approx 35,000 \times).

The scanning tunneling electron microscope (STM), developed in the 1980s, contains a tiny probe, whose tip may be only two or three atoms wide, that is moved across the specimen to be examined in a series of linear passes, like those made by the electron beam in a TV tube (CRT, Section 17-10). The tip, as it scans, remains very close to the surface of the specimen, about 1 nm above it, Fig. 27–16. A small voltage applied between the probe and the surface causes electrons to leave the surface and pass through the vacuum to the probe, by a process known as tunneling (discussed in Section 30-12). This "tunneling" current is very sensitive to the gap width, so a feedback mechanism can be used to raise and lower the probe to maintain a constant electron current. The probe's vertical motion, following the surface of the specimen, is then plotted as a function of position, producing a three-dimensional image of the surface. Surface features as fine as the size of an atom can be resolved: a resolution better than 0.1 nm laterally and 0.01 nm or better vertically. This kind of resolution has given a great impetus to the study of the surface structure of materials. The "topographic" image of a surface actually represents the distribution of electron charge.

The atomic force microscope (AFM), developed in the 1980s, is in many ways similar to an STM, but can be used on a wider range of sample materials. Instead of detecting an electric current, the AFM measures the force between a cantilevered tip and the sample, a force which depends strongly on the tip-sample separation at each point. The tip is moved as for the STM.

FIGURE 27-16 Probe tip of scanning tunneling electron microscope moves up and down to maintain constant tunneling current. A plot of the probe's motion produces an image of the surface.

27-10 Early Models of the Atom

The idea that matter is made up of atoms was accepted by most scientists by 1900. With the discovery of the electron in the 1890s, scientists began to think of the atom itself as having a structure with electrons as part of that structure. We now introduce our modern approach to the atom and the quantum theory with which it is intertwined.¹

'Some readers may say: "Tell us the facts as we know them today, and don't bother us with the historical background and its outmoded theories." Such an approach would ignore the creative aspect of science and thus give a false impression of how science develops. Moreover, it is not really possible to understand today's view of the atom without insight into the concepts that led to it.

Rutherford's planetary model

A typical model of the atom in the 1890s visualized the atom as a homogeneous sphere of positive charge inside of which there were tiny negatively charged electrons, a little like plums in a pudding, Fig. $27-17$.

Around 1911, Ernest Rutherford (1871–1937) and his colleagues performed experiments whose results contradicted the plum-pudding model of the atom. In these experiments a beam of positively charged "alpha (α) particles" was directed at a thin sheet of metal foil such as gold, Fig. 27–18a. (These newly discovered α particles were emitted by certain radioactive materials and were soon shown to be doubly ionized helium atoms—that is, having a charge of $+2e$.) It was expected from the plumpudding model that the alpha particles would not be deflected significantly because electrons are so much lighter than alpha particles, and the alpha particles should not have encountered any massive concentration of positive charge to strongly repel them. The experimental results completely contradicted these predictions. It was found that most of the alpha particles passed through the foil unaffected, as if the foil were mostly empty space. And of those deflected, a few were deflected at very large angles—some even backward, nearly in the direction from which they had come. This could happen, Rutherford reasoned, only if the positively charged alpha particles were being repelled by a massive positive charge concentrated in a very small region of space (see Fig. 27–18b). He hypothesized that the atom must

FIGURE 27-19 Rutherford's

model of the atom, in which electrons orbit a tiny positive nucleus (not to scale). The atom is visualized as mostly empty space.

positively charged nucleus.

consist of a tiny but massive positively charged nucleus, containing over 99.9% of the mass of the atom, surrounded by electrons some distance away. The electrons would be moving in orbits about the nucleus-much as the planets move around the Sun—because if they were at rest, they would fall into the nucleus due to electrical attraction, Fig. 27-19. Rutherford's experiments suggested that the nucleus must have a radius of about 10^{-15} to 10^{-14} m. From kinetic theory, and especially Einstein's analysis of Brownian motion (see Section 13-1), the radius of atoms was estimated to be about 10^{-10} m. Thus the electrons would seem to be at a distance from the nucleus of about 10,000 to 100,000 times the radius of the nucleus itself. (If the nucleus were the size of a baseball, the atom would have the diameter of a big city several kilometers across.) So an atom would be mostly empty space.

Rutherford's "planetary" model of the atom (also called the "nuclear model of the atom") was a major step toward how we view the atom today. It was not, however, a complete model and presented some major problems, as we shall see.

770 CHAPTER 27 Early Quantum Theory and Models of the Atom

27-11 Atomic Spectra: Key to the Structure of the Atom

Earlier in this Chapter we saw that heated solids (as well as liquids and dense gases) emit light with a continuous spectrum of wavelengths. This radiation is assumed to be due to oscillations of atoms and molecules, which are largely governed by the interaction of each atom or molecule with its neighbors.

Rarefied gases can also be excited to emit light. This is done by intense heating, or more commonly by applying a high voltage to a "discharge tube" containing the gas at low pressure, Fig. 27–20. The radiation from excited gases

had been observed early in the nineteenth century, and it was found that the spectrum was not continuous, but *discrete*. Since excited gases emit light of only certain wavelengths, when this light is analyzed through the slit of a spectroscope or spectrometer, a line spectrum is seen rather than a continuous spectrum. The line spectra emitted by a number of elements in the visible region are shown here in Fig. $27-21$, and also in Chapter 24, Fig. 24-28. The emission spectrum is characteristic of the material and can serve as a type of "fingerprint" for identification of the gas.

We also saw (Chapter 24) that if a continuous spectrum passes through a rarefied gas, dark lines are observed in the emerging spectrum, at wavelengths corresponding to lines normally emitted by the gas. This is called an absorption spectrum (Fig. 27–21c), and it became clear that gases can absorb light at the same frequencies at which they emit. Using film sensitive to ultraviolet and to infrared light, it was found that gases emit and absorb discrete frequencies in these regions as well as in the visible.

FIGURE 27-21 Emission spectra of the gases (a) atomic hydrogen, (b) helium, and (c) the *solar* absorption spectrum.

FIGURE 27-22 Balmer series of lines for hydrogen.

FIGURE 27-23 Line spectrum of atomic hydrogen. Each series fits the formula $\frac{1}{\lambda} = R \left(\frac{1}{n'^2} - \right)$ where $n' = 1$ for the Lyman series, $n' = 2$ for the Balmer series, $n' = 3$ for the Paschen series, and so on; n can take on all integer values from $n = n' + 1$ up to infinity. The only lines in the visible region of the electromagnetic spectrum are part of the Balmer series.

In low density gases, the atoms are far apart on the average and hence the light emitted or absorbed is assumed to be by individual atoms rather than through interactions between atoms, as in a solid, liquid, or dense gas. Thus the line spectra serve as a key to the structure of the atom: any theory of atomic structure must be able to explain why atoms emit light only of discrete wavelengths, and it should be able to predict what these wavelengths are.

Hydrogen is the simplest atom—it has only one electron orbiting its nucleus. It also has the simplest spectrum. The spectrum of most atoms shows little apparent regularity. But the spacing between lines in the hydrogen spectrum decreases in a regular way, Fig. 27-22. Indeed, in 1885, J. J. Balmer (1825–1898) showed that the four lines in the visible portion of the hydrogen spectrum (with measured wavelengths 656 nm, 486 nm, 434 nm, and 410 nm) have wavelengths that fit the formula

$$
\frac{1}{\lambda} = R\bigg(\frac{1}{2^2} - \frac{1}{n^2}\bigg), \qquad n = 3, 4, \cdots.
$$
 (27-9)

Here *n* takes on the values 3, 4, 5, 6 for the four visible lines, and *R*, called the **Rydberg constant**, has the value $R = 1.0974 \times 10^{7} \text{ m}^{-1}$. Later it was found that this **Balmer series** of lines extended into the UV region, ending at $\lambda = 365$ nm, as shown in Fig. 27–22. Balmer's formula, Eq. 27–9, also worked for these lines with higher integer values of n . The lines near 365 nm became too close together to distinguish, but the limit of the series at 365 nm corresponds to $n = \infty$ (so $1/n^2 = 0$ in Eq. 27-9).

Later experiments on hydrogen showed that there were similar series of lines in the UV and IR regions, and each series had a pattern just like the Balmer series, but at different wavelengths, Fig. 27-23. Each of these series was found to fit a formula with the same form as Eq. 27–9 but with the $1/2^2$ replaced by $1/1^2$, $1/3^2$, $1/4^2$, and so on. For example, the so-called Lyman series contains lines with wavelengths from 91 nm to 122 nm (in the UV region) and fits the formula

$$
\frac{1}{\lambda} = R\bigg(\frac{1}{1^2} - \frac{1}{n^2}\bigg), \qquad n = 2, 3, \cdots.
$$

And the wavelengths of the Paschen series (in the IR region) fit

$$
\frac{1}{\lambda} = R\bigg(\frac{1}{3^2} - \frac{1}{n^2}\bigg), \qquad n = 4, 5, \cdots.
$$

The Rutherford model was unable to explain why atoms emit line spectra. It had other difficulties as well. According to the Rutherford model, electrons orbit the nucleus, and since their paths are curved the electrons are accelerating. Hence they should give off light like any other accelerating electric charge (Chapter 22). Since light carries off energy and energy is conserved, the electron's own energy must decrease to compensate. Hence electrons would be

expected to spiral into the nucleus. As they spiraled inward, their frequency would increase in a short time and so too would the frequency of the light emitted. Thus the two main difficulties of the Rutherford model are these: (1) it predicts that light of a continuous range of frequencies will be emitted, whereas experiment shows line spectra; (2) it predicts that atoms are unstable electrons would quickly spiral into the nucleus—but we know that atoms in general are stable, because there is stable matter all around us.

Clearly Rutherford's model was not sufficient. Some sort of modification was needed, and Niels Bohr provided it in a model that included the quantum hypothesis. Although the Bohr model has been superceded, it did provide a crucial stepping stone to our present understanding. And some aspects of the Bohr model are still useful today, so we examine it in detail in the next Section.

27-12 The Bohr Model

Bohr had studied in Rutherford's laboratory for several months in 1912 and was convinced that Rutherford's planetary model of the atom had validity. But in order to make it work, he felt that the newly developing quantum theory would somehow have to be incorporated in it. The work of Planck and Einstein had shown that in heated solids, the energy of oscillating electric charges must change discontinuously—from one discrete energy state to another, with the emission of a quantum of light. Perhaps, Bohr argued, the electrons in an atom also cannot lose energy continuously, but must do so in quantum "jumps." In working out his model during the next year, Bohr postulated that electrons move about the nucleus in circular orbits, but that only certain orbits are allowed. He further postulated that an electron in each orbit would have a definite energy and would move in the orbit *without radiating energy* (even though this violated classical ideas since accelerating electric charges are supposed to emit EM waves; see Chapter 22). He thus called the possible orbits stationary states. Light is emitted, he hypothesized, only when an electron jumps from a higher (upper) stationary state to another of lower energy. When such a jump occurs, a single photon of light is emitted whose energy, by energy conservation, is given by

$$
hf = E_{\rm u} - E_{\rm l},\tag{27-10}
$$

where E_u refers to the energy of the upper state and E_l the energy of the lower state. See Fig. $27-24$.

Bohr set out to determine what energies these orbits would have in the simplest atom, hydrogen; then the spectrum of light emitted could be predicted from Eq. 27–10. In the Balmer formula he had the key he was looking for. Bohr quickly found that his theory would be in accord with the Balmer formula if he assumed that the electron's angular momentum L is quantized and equal to an integer *n* times $h/2\pi$. As we saw in Chapter 8 angular momentum is given by $L = I\omega$, where I is the moment of inertia and ω is the angular velocity. For a single particle of mass m moving in a circle of radius r with speed v, $I = mr^2$ and $\omega = v/r$; hence, $L = I\omega = (mr^2)(v/r) = mvr$. Bohr's quantum condition is

$$
L = mvr_n = n\frac{h}{2\pi}, \qquad n = 1, 2, 3, \cdots,
$$
 (27-11)

where *n* is an integer and r_n is the radius of the nth possible orbit. The allowed orbits are numbered $1, 2, 3, \dots$, according to the value of *n*, which is called the principal quantum number of the orbit.

Equation 27–11 did not have a firm theoretical foundation. Bohr had searched for some "quantum condition," and such tries as $E = hf$ (where E represents the energy of the electron in an orbit) did not give results in accord with experiment. Bohr's reason for using Eq. 27–11 was simply that it worked; and we now look at how. In particular, let us determine what the Bohr theory predicts for the measurable wavelengths of emitted light.

Stationary state

FIGURE 27-24 An atom emits a photon (energy = hf) when its energy changes from E_u to a lower energy E_I .

Angular momentum quantized

Quantum number, n

FIGURE 27-25 Electric force (Coulomb's law) keeps the negative electron in orbit around the positively charged nucleus.

An electron in a circular orbit of radius r (Fig. 27–25) would have a centripetal acceleration v^2/r produced by the electrical force of attraction between the negative electron and the positive nucleus. This force is given by Coulomb's law,

$$
F = k \frac{(Ze)(e)}{r^2},
$$

where $k = 1/4\pi\epsilon_0 = 9.00 \times 10^9 \,\text{N} \cdot \text{m}^2/\text{C}^2$. The charge on the electron is $q_1 = -e$, and that on the nucleus is $q_2 = +Ze$, where Z is the number of positive charges[†] (i.e., protons). For the hydrogen atom, $Z = +1$.

In Newton's second law, $F = ma$, we substitute Coulomb's law for F and $a = v^2/r_n$ for a particular allowed orbit of radius r_n , and obtain

$$
F = ma
$$

$$
k \frac{Ze^2}{r_n^2} = \frac{mv^2}{r_n}
$$

We solve this for r_n ,

$$
r_n = \frac{kZe^2}{mv^2},
$$

and then substitute for v from Eq. 27-11 (which says $v = nh/2\pi mr_n$):

$$
r_n = \frac{kZe^2 4\pi^2 mr_n^2}{n^2h^2}.
$$

We solve for r_n (it appears on both sides, so we cancel one of them) and find

$$
r_n = \frac{n^2 h^2}{4\pi^2 m k Z e^2} = \frac{n^2}{Z} r_1
$$
 (27-12)

where

$$
r_1 = \frac{h^2}{4\pi^2 m k e^2}.
$$

Equation 27-12 gives the radii of each possible orbit. The smallest orbit is for $n = 1$, and for hydrogen (Z = 1) has the value

$$
r_1 = \frac{(1)^2 (6.626 \times 10^{-34} \,\text{J} \cdot \text{s})^2}{4(3.14)^2 (9.11 \times 10^{-31} \,\text{kg})(9.00 \times 10^9 \,\text{N} \cdot \text{m}^2/\text{C}^2)(1.602 \times 10^{-19} \,\text{C})^2}
$$
\n
$$
r_1 = 0.529 \times 10^{-10} \,\text{m}.
$$
\n(27-13)

Bohr radius

The radius of the smallest orbit in hydrogen,
$$
r_1
$$
, is sometimes called the **Bohr radius**. From Eq. 27–12, we see that the radii of the larger orbits[‡] increase as n^2 , so

$$
r_2 = 4r_1 = 2.12 \times 10^{-10} \text{ m},
$$

\n
$$
r_3 = 9r_1 = 4.76 \times 10^{-10} \text{ m},
$$

\n
$$
\vdots
$$

\n
$$
r_n = n^2 r_1, \qquad n = 1, 2, 3, \cdots.
$$

The first four orbits are shown in Fig. 27-26. Notice that, according to Bohr's model, an electron can exist only in the orbits given by Eq. 27-12. There are no allowable orbits in between.

For an atom with $Z \neq 1$, we can write the orbital radii, r_n , using Eq. 27–12:

$$
r_n = \frac{n^2}{Z} (0.529 \times 10^{-10} \,\mathrm{m}), \qquad n = 1, 2, 3, \cdots.
$$
 (27-14)

In each of its possible orbits, the electron in a Bohr model atom would have

'We include Z in our derivation so that we can treat other single-electron ("hydrogenlike") atoms such as the ions He⁺ (Z = 2) and Li²⁺ (Z = 3). Helium in the neutral state has two electrons; if one electron is missing, the remaining He⁺ ion consists of one electron revolving around a nucleus of charge +2e. Similarly, doubly ionized lithium, Li²⁺, also has a single electron, and in this case $Z = 3$.

⁸Be careful not to believe that these well-defined orbits actually exist. Today electrons are better thought of as forming "clouds," as discussed in Chapter 28.

774 CHAPTER 27 Early Quantum Theory and Models of the Atom

FIGURE 27–26 Possible orbits in the Bohr model of hydrogen;
$$
r_1 = 0.529 \times 10^{-10}
$$
 m.

a definite energy, as the following calculation shows. The total energy equals the sum of the kinetic and potential energies. The potential energy of the electron is given by $PE = qV = -eV$, where V is the potential due to a point charge $+Ze$ as given by Eq. 17–5: $V = kQ/r = kZe/r$. So

$$
PE = -eV = -k\frac{Ze^2}{r}.
$$

The total energy E_n for an electron in the n^{th} orbit of radius r_n is the sum of the kinetic and potential energies:

$$
E_n = \frac{1}{2}mv^2 - \frac{kZe^2}{r_n}.
$$

When we substitute v from Eq. 27–11 and r_n from Eq. 27–12 into this equation, we obtain

$$
E_n = -\frac{2\pi^2 Z^2 e^4 m k^2}{h^2} \frac{1}{n^2} \qquad n = 1, 2, 3, \cdots.
$$
 (27-15a) Energy level

If we evaluate the constant term in Eq. $27-15a$ and convert it to electron volts, as is customary in atomic physics, we obtain

$$
E_n = -(13.6 \text{ eV}) \frac{Z^2}{n^2}, \qquad n = 1, 2, 3, \cdots.
$$
 (27-15b)

The lowest energy level $(n = 1)$ for hydrogen $(Z = 1)$ is

$$
E_1 = -13.6 \,\mathrm{eV}.
$$

Since n^2 appears in the denominator of Eq. 27–15b, the energies of the larger orbits in hydrogen $(Z = 1)$ are given by

$$
E_n = \frac{-13.6 \text{ eV}}{n^2}.
$$

For example,

$$
E_2 = \frac{-13.6 \text{ eV}}{4} = -3.40 \text{ eV},
$$

\n
$$
E_3 = \frac{-13.6 \text{ eV}}{9} = -1.51 \text{ eV}.
$$

\n
$$
E_4 = \frac{-13.6 \text{ eV}}{9} = -1.51 \text{ eV}.
$$

\n
$$
y = 1.51 \text{ eV}.
$$

\n
$$
y = 1.51 \text{ eV}.
$$

We see that not only are the orbit radii quantized, but from Eqs. $27-15$, so is the energy. The quantum number n that labels the orbit radii also labels the energy levels. The lowest **energy level** or **energy state** has energy E_1 , and is called the **ground state.** The higher states, E_2 , E_3 , and so on, are called **excited states**.

Notice that although the energy for the larger orbits has a smaller numerical value, all the energies are less than zero. Thus, -3.4 eV is a greater energy than -13.6 eV. Hence the orbit closest to the nucleus (r_1) has the lowest total energy. The reason the energies have negative values has to do with the way we defined the zero for potential energy. For two point charges, $PE = kq_1q_2/r$ corresponds to zero PE when the two charges are infinitely far apart as discussed in Section $17-5$. Thus, an electron that can just barely be free from the atom by reaching $r = \infty$ (or, at least, far from the nucleus) with zero KE will have $E = \kappa E + p E = 0 + 0 = 0$, corresponding to $n = \infty$ in Eqs. 27–15. If an electron is free and has some kinetic energy, then $E > 0$. To remove an electron that is part of an atom requires an energy input (otherwise atoms would not be stable). Since $E \ge 0$ for a free electron, then it makes sense that an electron bound to an atom must have $E < 0$. That is, energy must be added to bring the electron's total energy up, from a negative value to at least zero in order to free it.

The minimum energy required to remove an electron from the ground state of an atom is called the binding energy or ionization energy. The ionization energy for hydrogen has been measured to be 13.6 eV, and this corresponds precisely to removing an electron from the lowest state, $E_1 = -13.6$ eV, up to $E = 0$ where it can be free.

Binding energy (ionization energy)

Ground state of hydrogen

It is useful to show the various possible energy values as horizontal lines on an energy-level diagram. This is shown for hydrogen in Fig. $27-27$.[†] The electron in a hydrogen atom can be in any one of these levels according to Bohr theory. But it could never be in between, say at -9.0 eV. At room temperature, nearly all H atoms will be in the ground state $(n = 1)$. At higher temperatures, or during an electric discharge when there are many collisions between free electrons and atoms, many atoms can be in excited states $(n > 1)$. Once in an excited state, an atom's electron can jump down to a lower state, and give off a photon in the process. This is, according to the Bohr model, the origin of the emission spectra of excited gases.

Line spectra emission explained

> The vertical arrows in Fig. $27-27$ represent the transitions or jumps that correspond to the various observed spectral lines. For example, an electron jumping from the level $n = 3$ to $n = 2$ would give rise to the 656-nm line in the Balmer series, and the jump from $n = 4$ to $n = 2$ would give rise to the 486-nm line (see Fig. 27–22). We can predict wavelengths of the spectral lines emitted by combining Eq. 27–10 with Eq. 27–15. Since $hf = hc/\lambda$, we have from Eq. 27–10

$$
\frac{1}{\lambda} = \frac{hf}{hc} = \frac{1}{hc} (E_n - E_{n'}),
$$

 \sim \sim

where *n* refers to the upper state and *n'* to the lower state. Then using Eq. 27–15,

$$
\frac{1}{\lambda} = \frac{2\pi^2 Z^2 e^4 m k^2}{h^3 c} \bigg(\frac{1}{n'^2} - \frac{1}{n^2} \bigg).
$$
 (27-16)

This theoretical formula has the same form as the experimental Balmer formula, Eq. 27–9, with $n' = 2$. Thus we see that the Balmer series of lines corresponds to transitions or "jumps" that bring the electron down to the second energy level. Similarly, $n' = 1$ corresponds to the Lyman series and $n' = 3$ to the Paschen series (see Fig. 27–27).

[†]Note that above $E = 0$, an electron is free and can have any energy (E is not quantized). Thus there is a continuum of energy states above $E = 0$, as indicated in the energy-level diagram of Fig. 27-27.

When the constant in Eq. 27–16 is evaluated with $Z = 1$, it is found to have the measured value of the Rydberg constant, $R = 1.0974 \times 10^{7}$ m⁻¹ in Eq. 27–9, in accord with experiment (see Problem 53).

The great success of Bohr's model is that it gives an explanation for why atoms emit line spectra, and accurately predicts the wavelengths of emitted light for hydrogen. The Bohr model also explains absorption spectra: photons of just the right wavelength can knock an electron from one energy level to a higher one. To conserve energy, only photons that have just the right energy will be absorbed. This explains why a continuous spectrum of light entering a gas will emerge with dark (absorption) lines at frequencies that correspond to emission lines (Fig. 27-21c).

The Bohr theory also ensures the stability of atoms. It establishes stability by decree: the ground state is the lowest state for an electron and there is no lower energy level to which it can go and emit more energy. Finally, as we saw above, the Bohr theory accurately predicts the ionization energy of 13.6 eV for hydrogen. However, the Bohr model was not so successful for other atoms, and has been superseded as we shall discuss in the next Chapter. We discuss the Bohr model because it was an important start and because we still use the concept of stationary states, the ground state, and transitions between states. Also, the terminology used in the Bohr model is still used by chemists and spectroscopists.

EXAMPLE 27-12 Wavelength of a Lyman line. Use Fig. 27-27 to determine the wavelength of the first Lyman line, the transition from $n = 2$ to $n = 1$. In what region of the electromagnetic spectrum does this lie?

APPROACH We use Eq. 27–10, $hf = E_u - E_l$, with the energies obtained from Fig. 27-27 to find the energy and the wavelength of the transition. The region of the electromagnetic spectrum is found using the EM spectrum in Fig. 22-8.

SOLUTION In this case, $hf = E_2 - E_1 = \{-3.4 \text{ eV} - (-13.6 \text{ eV})\} = 10.2 \text{ eV} =$ $(10.2 \text{ eV})(1.60 \times 10^{-19} \text{ J/eV}) = 1.63 \times 10^{-18} \text{ J}$. Since $\lambda = c/f$, we have

$$
\lambda = \frac{c}{f} = \frac{hc}{E_2 - E_1} = \frac{(6.63 \times 10^{-34} \,\text{J} \cdot \text{s})(3.00 \times 10^8 \,\text{m/s})}{1.63 \times 10^{-18} \,\text{J}} = 1.22 \times 10^{-7} \,\text{m},
$$

or 122 nm, which is in the UV region of the EM spectrum, Fig. 22–8. See also Fig. 27-23.

NOTE An alternate approach would be to use Eq. 27-16 to find λ , and it gives the same result.

EXAMPLE 27-13 Wavelength of a Balmer line. Determine the wavelength of light emitted when a hydrogen atom makes a transition from the $n = 6$ to the $n = 2$ energy level according to the Bohr model.

APPROACH We can use Eq. 27-16 or its equivalent, Eq. 27-9, with $R = 1.097 \times 10^7 \,\mathrm{m}^{-1}$.

SOLUTION We find

$$
\frac{1}{\lambda} = (1.097 \times 10^7 \,\mathrm{m}^{-1}) \bigg(\frac{1}{4} - \frac{1}{36} \bigg) = 2.44 \times 10^6 \,\mathrm{m}^{-1}.
$$

So $\lambda = 1/(2.44 \times 10^6 \text{ m}^{-1}) = 4.10 \times 10^{-7} \text{ m}$ or 410 nm. This is the fourth line in the Balmer series, Fig. 27–22, and is violet in color.

Absorption lines explained

EXAMPLE 27-14 Absorption wavelength. Use Figure 27-27 to determine the maximum wavelength that hydrogen in its ground state can absorb. What would be the next smaller wavelength that would work?

APPROACH Maximum wavelength corresponds to minimum energy, and this would be the jump from the ground state up to the first excited state $(Fig. 27-27)$. The next smaller wavelength occurs for the jump from the ground state to the second excited state. In each case, the energy difference can be used to find the wavelength.

SOLUTION The energy needed to jump from the ground state to the first excited state is $13.6 \text{ eV} - 3.4 \text{ eV} = 10.2 \text{ eV}$; the required wavelength, as we saw in Example $27-12$, is 122 nm. The energy to jump from the ground state to the second excited state is $13.6 \text{ eV} - 1.5 \text{ eV} = 12.1 \text{ eV}$, which corresponds to a wavelength

$$
\lambda = \frac{c}{f} = \frac{hc}{hf} = \frac{hc}{E_3 - E_1}
$$

=
$$
\frac{(6.63 \times 10^{-34} \text{ J} \cdot \text{s})(3.00 \times 10^8 \text{ m/s})}{(12.1 \text{ eV})(1.60 \times 10^{-19} \text{ J/eV})} = 103 \text{ nm}.
$$

Additional Examples

EXAMPLE 27-15 lonization energy. (a) Use the Bohr model to determine the ionization energy of the $He⁺$ ion, which has a single electron. (b) Also calculate the maximum wavelength a photon can have to cause ionization.

APPROACH We want to determine the minimum energy required to lift the electron from its ground state and to barely reach the free state at $E = 0$. The ground state energy of He⁺ is given by Eq. 27–15b with $n = 1$ and $Z = 2$.

SOLUTION (a) Since all the symbols in Eq. 27-15b are the same as for the calculation for hydrogen, except that Z is 2 instead of 1, we see that E_1 will be $Z^2 = 2^2 = 4$ times the E_1 for hydrogen. That is,

$$
E_1 = 4(-13.6 \text{ eV}) = -54.4 \text{ eV}.
$$

Thus, to ionize the He^+ ion should require 54.4 eV, and this value agrees with experiment.

 (b) The maximum wavelength photon that can cause ionization will have energy $hf = 54.4$ eV and wavelength

$$
\lambda = \frac{c}{f} = \frac{hc}{hf} = \frac{(6.63 \times 10^{-34} \,\text{J} \cdot \text{s})(3.00 \times 10^8 \,\text{m/s})}{(54.4 \,\text{eV})(1.60 \times 10^{-19} \,\text{J/eV})} = 22.8 \,\text{nm}.
$$

If $\lambda > 22.8$ nm, ionization can not occur.

NOTE If the atom absorbed a photon of greater energy (wavelength shorter than 22.8 nm), the atom could still be ionized and the freed electron would have kinetic energy of its own.

In this last Example, we saw that E_1 for the He⁺ ion is four times more negative than that for hydrogen. Indeed, the energy-level diagram for He⁺ looks just like that for hydrogen, Fig. 27–27, except that the numerical values for each energy level are four times larger. Note, however, that we are talking here about the He⁺ ion. Normal (neutral) helium has two electrons and its energy level diagram is entirely different.

CONCEPTUAL EXAMPLE 27-16 Hydrogen at 20°C. Estimate the average kinetic energy of whole hydrogen atoms (not just the electrons) at room temperature, and use the result to explain why nearly all H atoms are in the ground state at room temperature, and hence emit no light.

RESPONSE According to kinetic theory (Chapter 13), the average KE of atoms or molecules in a gas is given by Eq. $13-8$:

$$
\overline{\text{KE}} = \frac{3}{2}kT,
$$

where $k = 1.38 \times 10^{-23}$ J/K is Boltzmann's constant, and T is the kelvin (absolute) temperature. Room temperature is about $T = 300$ K, so

$$
\overline{\text{KE}} = \frac{3}{2} (1.38 \times 10^{-23} \text{ J/K}) (300 \text{ K}) = 6.2 \times 10^{-21} \text{ J},
$$

or, in electron volts:

$$
\overline{\text{KE}} = \frac{6.2 \times 10^{-21} \text{ J}}{1.6 \times 10^{-19} \text{ J/eV}} = 0.04 \text{ eV}.
$$

The average KE of an atom as a whole is thus very small compared to the energy between the ground state and the next higher energy state $(13.6 \text{ eV} - 3.4 \text{ eV} = 10.2 \text{ eV})$. Any atoms in excited states quickly fall to the ground state and emit light. Once in the ground state, collisions with other atoms can transfer energy of only 0.04 eV on the average. A small fraction of atoms can have much more energy (see Section 13-11 on the distribution of molecular speeds), but even a KE that is 10 times the average is not nearly enough to excite atoms above the ground state. Thus, at room temperature, nearly all atoms are in the ground state. Atoms can be excited to upper states by very high temperatures, or by passing a current of high energy electrons through the gas, as in a discharge tube $(Fig. 27-20).$

Correspondence Principle

We should note that Bohr made some radical assumptions that were at variance with classical ideas. He assumed that electrons in fixed orbits do not radiate light even though they are accelerating (moving in a circle), and he assumed that angular momentum is quantized. Furthermore, he was not able to say how an electron moved when it made a transition from one energy level to another. On the other hand, there is no real reason to expect that in the tiny world of the atom electrons would behave as ordinary-sized objects do. Nonetheless, he felt that where quantum theory overlaps with the macroscopic world, it should predict classical results. This is the correspondence principle, already mentioned in regard to relativity (Section 26–11). This principle does work for Bohr's theory of the hydrogen atom. The orbit sizes and energies are quite different for $n = 1$ and $n = 2$, say. But orbits with $n = 100,000,000$ and 100,000,001 would be very close in size and energy (see Fig. 27-27). Indeed, jumps between such large orbits, which would approach macroscopic sizes, would be imperceptible. Such orbits would thus appear to be continuously spaced, which is what we expect in the everyday world.

Finally, it must be emphasized that the well-defined orbits of the Bohr model do not actually exist. The Bohr model is only a model, not reality. The idea of electron orbits was rejected a few years later, and today electrons are thought of (Chapter 28) as forming "probability clouds."

Correspondence principle

FIGURE 27-28 An ordinary standing wave compared to a circular standing wave.

FIGURE 27-29 When a wave does not close (and hence interferes destructively with itself), it rapidly dies out.

Ouantized orbits are a result of wave nature

27-13 de Broglie's Hypothesis Applied to Atoms

Bohr's theory was largely of an *ad hoc* nature. Assumptions were made so that theory would agree with experiment. But Bohr could give no reason why the orbits were quantized, nor why there should be a stable ground state. Finally, ten years later, a reason was proposed by Louis de Broglie. We saw in Section 27–8 that in 1923, de Broglie proposed that material particles, such as electrons, have a wave nature; and that this hypothesis was confirmed by experiment several years later.

One of de Broglie's original arguments in favor of the wave nature of electrons was that it provided an explanation for Bohr's theory of the hydrogen atom. According to de Broglie, a particle of mass m moving with a nonrelativistic speed v would have a wavelength (Eq. 27–8) of

$$
\lambda = \frac{h}{mv}
$$

Each electron orbit in an atom, he proposed, is actually a standing wave. As we saw in Chapter 11, when a violin or guitar string is plucked, a vast number of wavelengths are excited. But only certain ones—those that have nodes at the ends-are sustained. These are the *resonant* modes of the string. Waves with other wavelengths interfere with themselves upon reflection and their amplitudes quickly drop to zero. With electrons moving in circles, according to Bohr's theory, de Broglie argued that the electron wave was a circular standing wave that closes on itself, Fig. 27–28. If the wavelength of a wave does not close on itself, as in Fig. 27-29, destructive interference takes place as the wave travels around the loop, and the wave quickly dies out. Thus, the only waves that persist are those for which the circumference of the circular orbit contains a whole number of wavelengths, Fig. 27–30. The circumference of a Bohr orbit of radius r_n is $2\pi r_n$, so we have

$$
2\pi r_n = n\lambda, \qquad n = 1, 2, 3, \cdots
$$

When we substitute $\lambda = h/mv$, we get $2\pi r_n = nh/mv$, or

$$
mvr_n = \frac{nh}{2\pi}.
$$

This is just the quantum condition proposed by Bohr on an ad hoc basis, Eq. $27-11$. It is from this equation that the discrete orbits and energy levels were derived. Thus we have a first explanation for the quantized orbits and energy states in the Bohr model: they are due to the wave nature of the electron, and only

FIGURE 27-30 Standing circular waves for two, three, and five wavelengths on the circumference; n , the number of wavelengths, is also the quantum number.

resonant "standing" waves can persist.[†] This implies that the *wave-particle duality* is at the root of atomic structure.

In viewing the circular electron waves of Fig. 27–30, the electron is not to be thought of as following the oscillating wave pattern. In the Bohr model of hydrogen, the electron moves in a circle. The circular wave, on the other hand, represents the *amplitude* of the electron "matter wave," and in Fig. 27–30 the wave amplitude is shown superimposed on the circular path of the particle orbit for convenience.

Bohr's theory worked well for hydrogen and for one-electron ions. But it did not prove successful for multi-electron atoms. Bohr theory could not predict line spectra even for the next simplest atom, helium. It could not explain why some emission lines are brighter than others, nor why some lines are split into two or more closely spaced lines ("fine structure"). A new theory was needed and was indeed developed in the 1920s. This new and radical theory is called quantum mechanics. It finally solved the problem of atomic structure, but it gives us a very different view of the atom: the idea of electrons in well-defined orbits was replaced with the idea of electron "clouds." This new theory of quantum mechanics has given us a wholly different view of the basic mechanisms underlying physical processes.

[†]We note, however, that Eq. 27–11 is no longer considered valid, as discussed in the next Chapter.

Summary

Quantum theory has its origins in Planck's quantum hypothesis that molecular oscillations are quantized: their energy E can only be integer (n) multiples of hf , where h is Planck's constant and f is the natural frequency of oscillation:

$$
E = nhf. \tag{27-3}
$$

This hypothesis explained the spectrum of radiation emitted by a blackbody at high temperature.

Einstein proposed that for some experiments, light could be pictured as being emitted and absorbed as **quanta** (particles), which we now call photons, each with energy

$$
E = hf \tag{27-4}
$$

and momentum

$$
p = \frac{E}{c} = \frac{hf}{c} = \frac{h}{\lambda}.
$$
 (27-6)

He proposed the photoelectric effect as a test for the photon theory of light. In the photoelectric effect, the photon theory says that each incident photon can strike an electron in a material and eject it if it has sufficient energy. The maximum energy of ejected electrons is then linearly related to the frequency of the incident light.

The photon theory is also supported by the Compton effect and the observation of electron-positron pair production.

The wave-particle duality refers to the idea that light and matter (such as electrons) have both wave and particle properties. The wavelength of an object is given by

$$
\lambda = \frac{h}{p},\tag{27-8}
$$

where p is the momentum of the object ($p = mv$ for a particle of mass m and speed v).

The principle of complementarity states that we must be aware of both the particle and wave properties of light and of matter for a complete understanding of them.

Early models of the atom include the plum-pudding model, and Rutherford's planetary (or nuclear) model of an atom which consists of a tiny but massive positively charged nucleus surrounded (at a relatively great distance) by electrons.

To explain the line spectra emitted by atoms, as well as the stability of atoms, Bohr theory postulated that: (1) electrons bound in an atom can only occupy orbits for which the angular momentum is quantized, which results in discrete values for the radius and energy; (2) an electron in such a stationary state emits no radiation; (3) if an electron jumps to a lower state, it emits a photon whose energy equals the difference in energy between the two states; (4) the angular momentum L of atomic electrons is quantized by the rule

$$
L = \frac{nh}{2\pi},\tag{27-11}
$$

where *n* is an integer called the **quantum number**. The $n = 1$ state is the ground state, which in hydrogen has an energy $E_1 = -13.6$ eV. Higher values of *n* correspond to **excited** states, and their energies are

$$
E_n = -(13.6 \,\mathrm{eV}) \frac{Z^2}{n^2}.
$$
 (27-15b)

Atoms are excited to these higher states by collisions with other atoms or electrons, or by absorption of a photon of just the right frequency.

De Broglie's hypothesis that electrons (and other matter) have a wavelength $\lambda = h/mv$ gave an explanation for Bohr's quantized orbits by bringing in the wave-particle duality: the orbits correspond to circular standing waves in which the circumference of the orbit equals a whole number of wavelengths.

Questions

- 1. What can be said about the relative temperatures of whitish-yellow, reddish, and bluish stars? Explain.
- 2. If energy is radiated by all objects, why can we not see them in the dark? (See also Section 14–8.)
- 3. Does a lightbulb at a temperature of 2500 K produce as white a light as the Sun at 6000 K? Explain.
- 4. Darkrooms for developing black-and-white film were sometimes lit by a red bulb. Why red? Would such a bulb work in a darkroom for developing color photographs?
- 5. If the threshold wavelength in the photoelectric effect increases when the emitting metal is changed to a different metal, what can you say about the work functions of the two metals?
- 6. Explain why the existence of a cutoff frequency in the photoelectric effect more strongly favors a particle theory rather than a wave theory of light.
- 7. UV light causes sunburn, whereas visible light does not. Suggest a reason.
- 8. If an X-ray photon is scattered by an electron, does its wavelength change? If so, does it increase or decrease?
- 9. In both the photoelectric effect and in the Compton effect, a photon collides with an electron causing the electron to fly off. What then, is the difference between the two processes?
- 10. Consider a point source of light. How would the intensity of light vary with distance from the source according to (a) wave theory, (b) particle (photon) theory? Would this help to distinguish the two theories?
- 11. Explain how the photoelectric circuit of Fig. 27-6 could be used in (a) a burglar alarm, (b) a smoke detector, (c) a photographic light meter.
- 12. Why do we say that light has wave properties? Why do we say that light has particle properties?
- 13. Why do we say that electrons have wave properties? Why do we say that electrons have particle properties?
- 14. What is the difference between a photon and an electron? Be specific: make a list.
- 15. If an electron and a proton travel at the same speed, which has the shorter wavelength? Explain.
- 16. In Rutherford's planetary model of the atom, what keeps the electrons from flying off into space?
- 17. How can you tell if there is oxygen near the surface of the Sun?
- 18. When a wide spectrum of light passes through hydrogen gas at room temperature, absorption lines are observed that correspond only to the Lyman series. Why don't we observe the other series?
- 19. Explain how the closely spaced energy levels for hydrogen near the top of Fig. 27-27 correspond to the closely spaced spectral lines at the top of Fig. 27-22.
- 20. Is it possible for the de Broglie wavelength of a "particle" to be greater than the dimensions of the particle? To be smaller? Is there any direct connection?
- 21. In a helium atom, which contains two electrons, do you think that on average the electrons are closer to the nucleus or farther away than in a hydrogen atom? Why?
- 22. How can the spectrum of hydrogen contain so many lines when hydrogen contains only one electron?
- 23. The Lyman series is brighter than the Balmer series, because this series of transitions ends up in the most common state for hydrogen, the ground state. Why then was the Balmer series discovered first?
- 24. Use conservation of momentum to explain why photons emitted by hydrogen atoms have slightly less energy than that predicted by Eq. 27-10.
- 25. The work functions for sodium and cesium are 2.28 eV and 2.14 eV, respectively. For incident photons of a given frequency, which metal will give a higher maximum kinetic energy for the electrons?
- $26.$ (a) Does a beam of infrared photons always have less energy than a beam of ultraviolet photons? Explain. (b) Does a single infrared photon always have less energy than a single ultraviolet photon?
- 27. Light of 450-nm wavelength strikes a metal surface, and a stream of electrons emerges from the metal. If light of the same intensity but of wavelength 400 nm strikes the surface, are more electrons emitted? Does the energy of the emitted electrons change? Explain.
- 28. Suppose we obtain an emission spectrum for hydrogen at very high temperature (when some of the atoms are in excited states), and an absorption spectrum at room temperature, when all atoms are in the ground state. Will the two spectra contain identical lines?

Problems

27-1 Discovery of the Electron

- 1. (I) What is the value of e/m for a particle that moves in a circle of radius 7.0 mm in a 0.86-T magnetic field if a perpendicular 320-V/m electric field will make the path straight?
- 2. (II) (a) What is the velocity of a beam of electrons that go undeflected when passing through crossed (perpendicular) electric and magnetic fields of magnitude 1.88×10^4 V/m and 2.90×10^{-3} T, respectively? (b) What is the radius of the electron orbit if the electric field is turned off?
- 3. (II) An oil drop whose mass is determined to be 2.8×10^{-15} kg is held at rest between two large plates separated by 1.0 cm when the potential difference between them is 340 V. How many excess electrons does this drop have?

27-2 Planck's Quantum Hypothesis

- 4. (I) How hot is a metal being welded if it radiates most strongly at 440 nm?
- 5. (I) Estimate the peak wavelength for radiation from (a) ice at 0° C, (b) a floodlamp at 3500 K, (c) helium at 4 K, (d) for the universe at $T = 2.725$ K, assuming blackbody emission. In what region of the EM spectrum is each?
- 6. (I) (*a*) What is the temperature if the peak of a blackbody spectrum is at 18.0 nm ? (b) What is the wavelength at the peak of a blackbody spectrum if the body is at a temperature of 2000 K?
- 7. (I) An HCl molecule vibrates with a natural frequency of 8.1×10^{13} Hz. What is the difference in energy (in joules and electron volts) between possible values of the oscillation energy?
- 8. (II) The steps of a flight of stairs are 20.0 cm high (vertically). If a 68.0-kg person stands with both feet on the same step, what is the gravitational potential energy of this person, relative to the ground, on (a) the first step, (b) the second step, (c) the third step, (d) the n^{th} step? (e) What is the change in energy as the person descends from step 6 to step 2?
- 9. (II) Estimate the peak wavelength of light issuing from the pupil of the human eye (which approximates a blackbody) assuming normal body temperature.

27-3 and 27-4 Photons and the Photoelectric Effect

- 10. (I) What is the energy of photons (joules) emitted by an 88.5-MHz FM radio station?
- $11.$ (I) What is the energy range (in joules and eV) of photons in the visible spectrum, of wavelength 400 nm to 750 nm?
- 12. (I) A typical gamma ray emitted from a nucleus during radioactive decay may have an energy of 300 keV. What is its wavelength? Would we expect significant diffraction of this type of light when it passes through an everyday opening, like a door?
- 13. (I) About 0.1 eV is required to break a "hydrogen bond" in a protein molecule. Calculate the minimum frequency and maximum wavelength of a photon that can accomplish this.
- 14. (I) Calculate the momentum of a photon of yellow light of wavelength 6.00×10^{-7} m.
- **15.** (I) What is the momentum of a $\lambda = 0.010$ nm X-ray photon?
- 16. (II) The human eye can respond to as little as 10^{-18} J of light energy. For a wavelength at the peak of visual sensitivity, 550 nm, how many photons lead to an observable flash?
- 17. (II) What minimum frequency of light is needed to eject electrons from a metal whose work function is 4.3×10^{-19} J?
- 18. (II) What is the longest wavelength of light that will emit electrons from a metal whose work function is 3.10 eV?
- 19. (II) The work functions for sodium, cesium, copper, and iron are 2.3, 2.1, 4.7, and 4.5 eV, respectively. Which of these metals will not emit electrons when visible light shines on it?
- 20. (II) In a photoelectric-effect experiment it is observed that no current flows unless the wavelength is less than 570 nm. (*a*) What is the work function of this material? (b) What is the stopping voltage required if light of wavelength 400 nm is used?
- 21. (II) What is the maximum kinetic energy of electrons ejected from barium $(W_0 = 2.48 \text{ eV})$ when illuminated by white light, $\lambda = 400$ to 750 nm?
- 22. (II) Barium has a work function of 2.48 eV. What is the maximum kinetic energy of electrons if the metal is illuminated by UV light of wavelength 365 nm? What is their speed?
- 23. (II) When UV light of wavelength 285 nm falls on a metal surface, the maximum kinetic energy of emitted electrons is 1.40 eV. What is the work function of the metal?
- 24. (II) The threshold wavelength for emission of electrons from a given surface is 350 nm. What will be the maximum kinetic energy of ejected electrons when the wavelength is changed to (a) 280 nm, (b) 360 nm?
- 25. (II) A certain type of film is sensitive only to light whose wavelength is less than 660 nm. What is the energy (eV and kcal/mol) needed for the chemical reaction to occur which causes the film to change?
- 26. (II) When 230-nm light falls on a metal, the current through a photoelectric circuit (Fig. 27–6) is brought to zero at a stopping voltage of 1.64 V. What is the work function of the metal?
- 27. (II) In a photoelectric experiment using a clean sodium surface, the maximum energy of the emitted photons was measured for a number of different incident frequencies, with the following results.

Plot the graph of these results and find: (a) Planck's constant; (b) the cutoff frequency of sodium; (c) the work function.

28. (II). Show that the energy E (in electron volts) of a photon whose wavelength is λ (nm) is given by

$$
E = \frac{1.240 \times 10^3 \text{ eV} \cdot \text{nm}}{\lambda \text{ (nm)}}.
$$

* 27-4 Compton Effect

- * 29. (II) The quantity h/m_0c , which has the dimensions of length, is called the Compton wavelength. Determine the Compton wavelength for (a) an electron, (b) a proton. (c) Show that if a photon has wavelength equal to the Compton wavelength of a particle, the photon's energy is equal to the rest energy of the particle.
- *30. (II) X-rays of wavelength $\lambda = 0.120$ nm are scattered from carbon. What is the Compton wavelength shift for photons detected at angles (relative to the incident beam) of (a) 45° , (b) 90° , (c) 180° ?
- *31. (III) In the Compton effect, a 0.100-nm photon strikes a free electron in a head-on collision and knocks it into the forward direction. The rebounding photon recoils directly backward. Use conservation of (relativistic) energy and momentum to determine (a) the kinetic energy of the electron, and (b) the wavelength of the recoiling photon. (Note: use Eq. 27-6, but not Eq. 27-7.)

27-6 Pair Production

- 32. (I) How much total kinetic energy will an electron-positron pair have if produced by a 3.84-MeV photon?
- 33. (II) What is the longest wavelength photon that could produce a proton-antiproton pair? (Each has a mass of 1.67×10^{-27} kg.)
- 34. (II) What is the minimum photon energy needed to produce a $\mu^+ - \mu^-$ pair? The mass of each μ (muon) is 207 times the mass of the electron. What is the wavelength of such a photon?
- 35. (II) An electron and a positron, each moving at 1.0×10^{5} m/s, collide head on, disappear, and produce two photons, each with the same energy and momentum moving in opposite directions. What is the energy and momentum of each photon?
- 36. (II) A gamma-ray photon produces an electron-positron pair, each with a kinetic energy of 245 keV. What was the energy and wavelength of the photon?

27-8 Wave Nature of Matter

- 37. (I) Calculate the wavelength of a 0.23-kg ball traveling at $0.10 \,\mathrm{m/s}$.
- 38. (I) What is the wavelength of a neutron $(m =$ 1.67×10^{-27} kg) traveling at 6.5×10^4 m/s?
- 39. (I) Through how many volts of potential difference must an electron be accelerated to achieve a wavelength of 0.24 nm?
- 40. (II) Calculate the ratio of the kinetic energy of an electron to that of a proton if their wavelengths are equal. Assume that the speeds are nonrelativistic.
- 41. (II) An electron has a de Broglie wavelength $\lambda = 5.0 \times 10^{-10}$ m. (a) What is its momentum? (b) What is its speed? (c) What voltage was needed to accelerate it to this speed?
- 42. (II) What is the wavelength of an electron of energy (a) 10 eV , (b) 100 eV , (c) 1.0 keV ?
- 43. (II) Show that if an electron and a proton have the same nonrelativistic kinetic energy, the proton has the shorter wavelength.
- 44. (II) Calculate the de Broglie wavelength of an electron in your TV picture tube if it is accelerated by 30,000 V. Is it relativistic? How does its wavelength compare to the size of the "neck" of the tube, typically 5 cm? Do we have to worry about diffraction problems blurring our picture on the screen?
- 45. (III) A Ferrari with a mass of 1400 kg approaches a freeway underpass that is 10m across. At what speed must the car be moving, in order for it to have a wavelength such that it might somehow "diffract" after passing through this "single slit"? How do these conditions compare to normal freeway speeds of 30 m/s?

* 27-9 Electron Microscope

- * 46. (II) What voltage is needed to produce electron wavelengths of 0.20 nm? (Assume that the electrons are nonrelativistic.)
- $*47.$ (II) Electrons are accelerated by 2450 V in an electron microscope. What is the maximum possible resolution?

27-12 Bohr Model

- 48. (I) For the three hydrogen transitions indicated below, with n being the initial state and n' being the final state, is the transition an absorption or an emission? Which is higher, the initial state energy or the final state energy of the atom? Finally, which of these transitions involves the largest energy photon? (a) $n = 1$, $n' = 3$ (b) $n = 6$, $n' = 2$ (c) $n = 4$, $n' = 5$.
- 49. (I) How much energy is needed to ionize a hydrogen atom in the $n = 2$ state?
- 50. (I) The third longest wavelength in the Paschen series in hydrogen (Fig. 27-27) corresponds to what transition?

General Problems

- 64. The Big Bang theory states that the beginning of the universe was accompanied by a huge burst of photons. Those photons are still present today and make up the so-called cosmic microwave background radiation. The universe radiates like a blackbody with a temperature of about 2.7 K. Calculate the peak wavelength of this radiation.
- 65. At low temperatures, nearly all the atoms in hydrogen gas will be in the ground state. What minimum frequency photon is needed if the photoelectric effect is to be observed?
- 51. (I) Calculate the ionization energy of doubly ionized lithium, Li^{2+} , which has $Z = 3$.
- 52. (I) (a) Determine the wavelength of the second Balmer line ($n = 4$ to $n = 2$ transition) using Fig. 27–27. Determine likewise (b) the wavelength of the second Lyman line and (c) the wavelength of the third Balmer line.
- 53. (I) Evaluate the Rydberg constant R using Bohr theory (compare Eqs. $27-9$ and $27-16$) and show that its value is $R = 1.0974 \times 10^{7}$ m⁻¹.
- 54. (II) What is the longest wavelength light capable of ionizing a hydrogen atom in the ground state?
- 55. (II) What wavelength photon would be required to ionize a hydrogen atom in the ground state and give the ejected electron a kinetic energy of 10.0 eV?
- 56. (II) In the Sun, an ionized helium $(He⁺)$ atom makes a transition from the $n = 6$ state to the $n = 2$ state, emitting a photon. Can that photon be absorbed by hydrogen atoms present in the Sun? If so, between what energy states will the hydrogen atom jump?
- 57. (II) Construct the energy-level diagram for the $He⁺$ ion (see Fig. 27-27).
- 58. (II) Construct the energy-level diagram for doubly ionized lithium. Li^{2+} .
- 59. (II) What is the potential energy and the kinetic energy of an electron in the ground state of the hydrogen atom?
- 60. (II) An excited hydrogen atom could, in principle, have a radius of 1.00 mm. What would be the value of n for a Bohr orbit of this size? What would its energy be?
- 61. (II) Is the use of nonrelativistic formulas justified in the Bohr atom? To check, calculate the electron's velocity, v , in terms of c , for the ground state of hydrogen, and then calculate $\sqrt{1-v^2/c^2}$.
- 62. (III) Suppose an electron was bound to a proton, as in the hydrogen atom, but by the gravitational force rather than by the electric force. What would be the radius, and energy, of the first Bohr orbit?

27-13 de Broglie's Hypothesis Applied to Atoms

- 63. (III) Suppose a particle of mass m is confined to a onedimensional box of width L . According to quantum theory, the particle's wave (with $\lambda = h/mv$) is a standing wave with nodes at the edges of the box. (a) Show the possible modes of vibration on a diagram. (b) Show that the kinetic energy of the particle has quantized energies given by $KE = n^2 h^2 / 8mL^2$, where *n* is an integer. (c) Calculate the ground-state energy $(n = 1)$ for an electron confined to a box of width 0.50×10^{-10} m. (d) What is the ground-state energy, and speed, of a baseball $(m = 140 g)$ in a box 0.50 m wide? (e) An electron confined to a box has a ground-state energy of 22 eV. What is the width of the box?
- 66. A beam of 85-eV electrons is scattered from a crystal, as in X-ray diffraction, and a first-order peak is observed at $\theta = 38^{\circ}$. What is the spacing between planes in the diffracting crystal? (See Section 25–11.)
- 67. A microwave oven produces electromagnetic radiation at $\lambda = 12.2$ cm and produces a power of 760 W. Calculate the number of microwave photons produced by the microwave oven each second.
- 68. Sunlight reaching the Earth's surface has an intensity of about 1000 W/m^2 . Estimate how many photons per square meter per second this represents. Take the average wavelength to be 550 nm.
- 69. A beam of red laser light $(\lambda = 633 \text{ nm})$ hits a black wall and is fully absorbed. If this light exerts a total force $F = 5.5$ nN on the wall, how many photons per second are hitting the wall?
- 70. If a 100-W lightbulb emits 3.0% of the input energy as visible light (average wavelength 550 nm) uniformly in all directions, estimate how many photons per second of visible light will strike the pupil (4.0 mm diameter) of the eye of an observer 1.0 km away.
- 71. An electron and a positron collide head on, annihilate, and create two 0.90-MeV photons traveling in opposite directions. What were the initial kinetic energies of electron and positron?
- 72. By what potential difference must (a) a proton $(m =$ 1.67×10^{-27} kg), and (b) an electron $(m = 9.11 \times 10^{-31}$ kg), be accelerated to have a wavelength $\lambda = 5.0 \times 10^{-12}$ m?
- 73. In some of Rutherford's experiments (Fig. 27-18) the α particles (mass = 6.64 × 10⁻²⁷ kg) had a kinetic energy of 4.8 MeV. How close could they get to a gold nucleus (charge = $+79e$)? Ignore the recoil motion of the nucleus.
- 74. By what fraction does the mass of an H atom decrease when it makes an $n = 3$ to $n = 1$ transition?
- 75. Calculate the ratio of the gravitational to electric force for the electron in a hydrogen atom. Can the gravitational force be safely ignored?
- **76.** Electrons accelerated by a potential difference of 12.3 V pass through a gas of hydrogen atoms at room temperature. What wavelengths of light will be emitted?
- 77. In a particular photoelectric experiment, a stopping potential of 2.10 V is measured when ultraviolet light of wavelength 290 nm is incident on the metal. Using the same setup, what will the new stopping potential be if blue light of wavelength 440 nm is used, instead?
- 78. In an X-ray tube (see Fig. 25-35 and discussion in Section 25-11), the high voltage between filament and target is V. After being accelerated through this voltage, an electron strikes the target where it is decelerated (by positively charged nuclei) and in the process one or more X-ray photons are emitted. (a) Show that the photon of shortest wavelength will have

$$
\lambda_0 = \frac{hc}{eV}
$$

 (b) What is the shortest wavelength of X-ray emitted when accelerated electrons strike the face of a 30-kV television picture tube?

- 79. The intensity of the Sun's light in the vicinity of the Earth is about 1000 $W/m²$. Imagine a spacecraft with a mirrored square sail of dimension 1.0 km. Estimate how much thrust (in newtons) this craft will experience due to collisions with the Sun's photons. [Hint: assume the photons bounce off the sail with no change in the magnitude of their momentum.]
- 80. Light of wavelength 300 nm strikes a metal whose work function is 2.2 eV. What is the shortest de Broglie wavelength for the electrons that are produced as photoelectrons?
- 81. Photons of energy 6.0 eV are incident on a metal. It is found that current flows from the metal until a stopping potential of 4.0 V is applied. If the wavelength of the incident photons is doubled, what is the maximum kinetic energy of the ejected electrons? What would happen if the wavelength of the incident photons was tripled?
- 82. Visible light incident on a diffraction grating with slit spacing of 0.010 mm has the first maximum at an angle of 3.5° from the central peak. If electrons could be diffracted by the same grating, what electron velocity would produce the same diffraction pattern as the visible light?
- 83. (a) Suppose an unknown element has an absorption spectrum with lines at 2.5 , 4.7, and 5.1 eV above its ground state and an ionization energy of 11.5 eV. Draw an energy level diagram for this element. (b) If a 5.1-eV photon is absorbed by an atom of this substance, in which state was the atom before absorbing the photon? What will be the energies of the photons that can subsequently be emitted by this atom?
- 84. Light of wavelength 424 nm falls on a metal which has a work function of 2.28 eV . (a) How much voltage should be applied to bring the current to zero? (b) What is the maximum speed of the emitted electrons? (c) What is the de Broglie wavelength of these electrons?
- 85. An electron accelerated from rest by a 96-V potential difference is injected into a 3.67×10^{-4} T magnetic field where it travels in an 18-cm-diameter circle. Calculate e/m from this information.
- 86. Estimate the number of photons emitted by the Sun in a year. (Take the average wavelength to be 550 nm and the intensity of sunlight reaching the Earth (outer atmosphere) as $1350 W/m²$.)
- 87. Apply Bohr's assumptions to the Earth–Moon system to calculate the allowed energies and radii of motion. Given the known distance between the Earth and Moon, is the quantization of the energy and radius apparent?

Answers to Exercises

A: $\lambda_p = 725$ nm, so red. B: More 1000-nm photons (lower frequency). **C:** 5.50×10^{14} Hz, 545 nm.

 $D:$ Only λ . E: Decrease. A neon tube is a thin glass tube filled with neon (or other) gas that glows with a particular color when a current at high voltage passes through it. Gas atoms, excited to upper energy levels, jump down to lower energy levels and emit light (photons) whose wavelengths (color) are characteristic of the type of gas.

In this Chapter we study what quantum mechanics tells us about atoms and energy levels, and the effect of the exclusion principle.

CHAPTER

Quantum Mechanics of Atoms

ohr's model of the atom gave us a first (though rough) picture of what an atom is like. It proposed explanations for why there is emission and absorption of light by atoms at only certain wavelengths. The wavelengths of the line spectra and the ionization energy for hydrogen (and one-electron ions) are in excellent agreement with experiment. But the Bohr theory had important limitations. It was not able to predict line spectra for more complex atoms—not even for the neutral helium atom, which has only two electrons. Nor could it explain why emission lines, when viewed with great precision, consist of two or more very closely spaced lines (referred to as fine structure). The Bohr theory also did not explain why some spectral lines were brighter than others. And it could not explain the bonding of atoms in molecules or in solids and liquids.

From a theoretical point of view, too, the Bohr theory was not satisfactory: it was a strange mixture of classical and quantum ideas. Moreover, the wave-particle duality was not really resolved.

We mention these limitations of the Bohr theory not to disparage it—for it was a landmark in the history of science. Rather, we mention them to show why, in the early 1920s, it became increasingly evident that a new, more comprehensive

FIGURE 28-1 Erwin Schrödinger with Lise Meitner (see Chapter 31).

FIGURE 28-2 Werner Heisenberg (center) on Lake Como with Wolfgang Pauli (right) and Enrico Fermi (left).

theory was needed. It was not long in coming. Less than two years after de Broglie gave us his matter-wave hypothesis, Erwin Schrödinger (1887–1961; Fig. 28–1) and Werner Heisenberg $(1901-1976;$ Fig. 28-2) independently developed a new comprehensive theory.

28-1 Quantum Mechanics-A New Theory

The new theory, called quantum mechanics, has been extremely successful. It unifies the wave-particle duality into a single consistent theory and has successfully dealt with the spectra emitted by complex atoms, even the fine details. It explains the relative brightness of spectral lines and how atoms form molecules. It is also a much more general theory that covers all quantum phenomena from blackbody radiation to atoms and molecules. It has explained a wide range of natural phenomena and from its predictions many new practical devices have become possible. Indeed, it has been so successful that it is accepted today by nearly all physicists as the fundamental theory underlying physical processes.

Quantum mechanics deals mainly with the microscopic world of atoms and light. But this new theory, when it is applied to macroscopic phenomena, must be able to produce the old classical laws. This, the **correspondence principle** (already mentioned in Section $27-12$), is satisfied fully by quantum mechanics.

This doesn't mean we throw away classical theories such as Newton's laws. In the everyday world, the latter are far easier to apply and they give sufficiently accurate descriptions. But when we deal with high speeds, close to the speed of light, we must use the theory of relativity; and when we deal with the tiny world of the atom, we use quantum mechanics.

Although we won't go into the detailed mathematics of quantum mechanics, we will discuss the main ideas and how they involve the wave and particle properties of matter to explain atomic structure and other applications.

28-2 The Wave Function and Its Interpretation; the Double-Slit Experiment

The important properties of any wave are its wavelength, frequency, and amplitude. For an electromagnetic wave, the frequency (or wavelength) determines whether the light is in the visible spectrum or not, and if so, what color it is. We also have seen that the frequency is a measure of the energy of the corresponding photon ($E = hf$). The amplitude or displacement of an electromagnetic wave at any point is the strength of the electric (or magnetic) field at that point, and is related to the intensity of the wave (the brightness of the light). Correspondence principle

Wave function

For material particles such as electrons, quantum mechanics relates the wavelength to momentum according to de Broglie's formula, $\lambda = h/p$, Eq. 27–8. But what corresponds to the *amplitude* or *displacement* of a matter wave? The amplitude of an electromagnetic wave is represented by the electric and magnetic fields, E and B . In quantum mechanics, this role is played by the wave function, which is given the symbol Ψ (the Greek capital letter psi, pronounced "sigh"). Thus Ψ represents the wave displacement as a function of time and position, of a new kind of field which we might call a "matter" field or a matter wave.

To understand how to interpret the wave function Ψ , we make an analogy with light using the wave-particle duality.

We saw in Chapter 11 that the intensity I of any wave is proportional to the square of the amplitude. This holds true for light waves as well, as we saw in Chapter 22; that is,

 $I \propto E^2$.

where E is the electric field strength. From the *particle* point of view, the intensity of a light beam (of given frequency) is proportional to the number of photons, N , that pass through a given area per unit time. The more photons there are, the greater the intensity. Thus

 $I \propto E^2 \propto N$.

This proportion can be turned around so that we have

 $N \propto E^2$.

That is, the number of photons (striking a page of this book, say) is proportional to the square of the electric-field strength.

If the light beam is very weak, only a few photons will be involved. Indeed, it is possible to "build up" a photograph in a camera using very weak light so the effect of individual photons can be seen. If we are dealing with only one photon, the relationship above $(N \propto E^2)$ can be interpreted in a slightly different way. At any point the square of the electric field strength, E^2 , is a measure of the *probability* that a photon will be at that location. At points where E^2 is large, there is a high probability the photon will be there; where E^2 is small, the probability is low.

We can interpret matter waves in the same way, as was first suggested by Max Born (1882–1970) in 1927. The wave function Ψ may vary in magnitude from point to point in space and time. If Ψ describes a collection of many electrons, then Ψ^2 at any point will be proportional to the number of electrons expected to be found at that point. When dealing with small numbers of electrons we can't make very exact predictions, so Ψ^2 takes on the character of a probability. If Ψ , which depends on time and position, represents a single electron (say, in an atom), then Ψ^2 is interpreted as follows: Ψ^2 at a certain point in space and time represents the probability of finding the electron at the given position and time.

Probability $\propto \Psi^2$

FIGURE 28-3 Parallel beam, of light or electrons, falls on two slits whose sizes are comparable to the wavelength. An interference pattern is observed.

Double-Slit Interference Experiment for Electrons

To understand this better, we take as a thought experiment the familiar double-slit experiment, and consider it both for light and for electrons.

Consider two slits whose size and separation are on the order of the wavelength of whatever we direct at them, either light or electrons, Fig. 28–3. We know very well what would happen in this case for light, since this is just Young's double-slit experiment (Section 24–3): an interference pattern would be seen on the screen behind. If light were replaced by electrons with wavelength comparable to the slit size, they too would produce an interference pattern (recall Fig. 27–12). In the case of light, the pattern would be visible to the eye or could be recorded on film. For electrons, a fluorescent screen could be used (it glows where an electron strikes).

If we reduced the flow of electrons (or photons) so they passed through the slits one at a time, we would see a flash each time one struck the screen. At first, the flashes would seem random. Indeed, there is no way to predict just where any one electron would hit the screen. If we let the experiment run for a long time, and kept track of where each electron hit the screen, we would soon see a pattern emerging—the interference pattern predicted by the wave theory; see Fig. 28–4. Thus, although we could not predict where a given electron would strike the screen, we could predict probabilities. (The same can be said for photons.) The probability, as mentioned before, is proportional to Ψ^2 . Where Ψ^2 is zero, we would get a minimum in the interference pattern. And where Ψ^2 is a maximum, we would get a peak in the interference pattern.

The interference pattern would thus occur even when electrons (or photons) passed through the slits one at a time. So the interference pattern could not arise from the interaction of one electron with another. It is as if an electron passed through both slits at the same time, interfering with itself. This is possible because an electron is not precisely a particle. It is as much a wave as it is a particle, and a wave could travel through both slits at once. But what would happen if we covered one of the slits so we knew that the electron passed through the other one, and a little later we covered the second slit so the electron had to have passed through the first? The result would be that no interference pattern would be seen. We would see, instead, two bright areas (or diffraction patterns) on the screen behind the slits. This confirms our idea that if both slits are open, the screen shows an interference pattern as if each electron passed through both slits, like a wave. Yet each electron would make a tiny spot on the screen as if it were a particle.

The main point of this discussion is this: if we treat electrons (and other particles) as if they were waves, then Ψ represents the wave amplitude. If we treat them as particles, then we must treat them on a *probabilistic* basis. The square of the wave function, Ψ^2 , gives the probability of finding a given electron at a given point. We cannot predict—or even follow—the path of a single electron precisely through space and time.

B The Heisenberg Uncertainty Principle

Whenever a measurement is made, some uncertainty is always involved. For example, you cannot make an absolutely exact measurement of the length of a table. Even with a measuring stick that has markings 1 mm apart, there will be an inaccuracy of perhaps $\frac{1}{2}$ mm or so. More precise instruments will produce more precise measurements. But there is always some uncertainty involved in a measurement, no matter how good the measuring device. We expect that by using more precise instruments, the uncertainty in a measurement can be made indefinitely small.

But according to quantum mechanics, there is actually a limit to the accuracy of certain measurements. This limit is not a restriction on how well instruments can be made; rather, it is inherent in nature. It is the result of two factors: the wave-particle duality, and the unavoidable interaction between the thing observed and the observing instrument. Let us look at this in more detail.

To make a measurement on an object without disturbing it, at least a little, is not possible. Consider trying to locate a Ping-pong ball in a completely dark room. You grope about trying to find its position; and just when you touch it with your finger, it bounces away. Whenever we measure the position of an object, whether it's a ball or an electron, we always touch it with something else that gives us the information about its position. To locate a lost Ping-pong ball in a dark room, you could probe about with your hand or a stick; or you could shine a light and detect the light reflecting off the ball. When you search with your hand or a stick, you find the ball's position when you touch it. But when you touch the ball you unavoidably bump it, and give it some momentum.

FIGURE 28-4 Young's double-slit experiment done with electronsnote that the pattern is not evident with only a few electrons (top photo), but with more and more electrons (second and third photos), the familiar double-slit interference pattern (Chapter 24) is seen.

Thus you won't know its *future* position. The same would be true, but to a much lesser extent, if you observe the Ping-pong ball using light. In order to "see" the ball, at least one photon must scatter from it, and the reflected photon must enter your eve or some other detector. When a photon strikes an ordinary-sized object, it does not appreciably alter the motion or position of the object. But when a photon strikes a very tiny object like an electron, it can transfer momentum to the object and thus greatly change the object's motion and position in an unpredictable way. The mere act of measuring the position of an object at one time makes our knowledge of its future position imprecise.

Now let us see where the wave-particle duality comes in. Imagine a thought experiment in which we are trying to measure the position of an object, say an electron, with photons, Fig. 28–5. (The arguments would be similar if we were using, instead, an electron microscope.) As we saw in Chapter 25, objects can be seen to an accuracy at best of about the wavelength of the radiation used. If we want an accurate position measurement, we must use a short wavelength. But a short wavelength corresponds to high frequency and large momentum ($p = h/\lambda$); and the more momentum the photons have, the more momentum they can give the object when they strike it. If we use photons of longer wavelength, and correspondingly smaller momentum, the object's motion when struck by the photons will not be affected as much. But the longer wavelength means lower resolution, so the object's position will be less accurately known. Thus the act of observing produces an uncertainty in both the *position* and the *momentum* of the electron. This is the essence of the *uncertainty principle* first enunciated by Heisenberg in 1927.

Quantitatively, we can make an approximate calculation of the magnitude of this effect. If we use light of wavelength λ , the position can be measured at best to an accuracy of about λ . That is, the uncertainty in the position measurement, Δx , is approximately

 $\Delta x \approx \lambda$.

Suppose that the object can be detected by a single photon. The photon has a momentum $p_x = h/\lambda$. When the photon strikes our object, it will give some or all of this momentum to the object, Fig. $28-5$. Therefore, the final x momentum of our object will be uncertain in the amount

$$
\Delta p_x \approx \frac{h}{\lambda}
$$

since we can't tell beforehand how much momentum will be transferred. The product of these uncertainties is

$$
(\Delta x)(\Delta p_x) \approx h.
$$

The uncertainties could be worse than this, depending on the apparatus and the number of photons needed for detection. A more careful mathematical calculation shows the product of the uncertainties as, at best, about

$$
UNCENTY PRINCIPLE
$$

(Δx and Δp)

$$
(\Delta x)(\Delta p_x) \gtrsim \frac{h}{2\pi}.
$$
 (28-1)

This is a mathematical statement of the **Heisenberg uncertainty principle**, or, as it is sometimes called, the indeterminancy principle. It tells us that we cannot measure both the position and momentum of an object precisely at the same time. The more accurately we try to measure the position, so that Δx is small, the greater will be the uncertainty in momentum, Δp_x . If we try to measure the momentum very precisely, then the uncertainty in the position becomes large.

FIGURE 28-5 Thought experiment for observing an electron with a powerful light microscope. At least one photon must scatter from the electron (transferring some momentum to it) and enter the microscope.

The uncertainty principle does not forbid individual precise measurements, however. For example, in principle we could measure the position of an object exactly. But then its momentum would be completely unknown. Thus, although we might know the position of the object exactly at one instant, we could have no idea at all where it would be a moment later. The uncertainties expressed here are inherent in nature, and reflect the best precision theoretically attainable even with the best instruments.

Another useful form of the uncertainty principle relates energy and time, and we examine this as follows. The object to be detected has an uncertainty in position $\Delta x \approx \lambda$. The photon that detects it travels with speed c, and it takes a time $\Delta t \approx \Delta x/c \approx \lambda/c$ to pass through the distance of uncertainty. Hence, the measured time when our object is at a given position is uncertain by about

$$
\Delta t \approx \frac{\lambda}{c} \cdot
$$

Since the photon can transfer some or all of its energy $(= hf = hc/\lambda)$ to our object, the uncertainty in energy of our object as a result is

$$
\Delta E \approx \frac{hc}{\lambda}.
$$

The product of these two uncertainties is

$$
(\Delta E)(\Delta t) \approx h.
$$

A more careful calculation gives

$$
(\Delta E)(\Delta t) \gtrsim \frac{h}{2\pi}.
$$
 (28-2)

This form of the uncertainty principle tells us that the energy of an object can be uncertain (or can be interpreted as briefly nonconserved) by an amount ΔE for a time $\Delta t \approx h/(2\pi \Delta E)$.

The quantity $(h/2\pi)$ appears so often in quantum mechanics that for convenience it is given the symbol \hbar ("h-bar"). That is,

$$
\hbar = \frac{h}{2\pi} = \frac{6.626 \times 10^{-34} \,\text{J} \cdot \text{s}}{2\pi} = 1.055 \times 10^{-34} \,\text{J} \cdot \text{s}.
$$

By using this notation, Eqs. $28-1$ and $28-2$ for the uncertainty principle can be written

$$
(\Delta x)(\Delta p_x) \gtrsim \hbar
$$
 and $(\Delta E)(\Delta t) \gtrsim \hbar$.

We have been discussing the position and velocity of an electron as if it were a particle. But it isn't simply a particle. Indeed, we have the uncertainty principle because an electron—and matter in general—has wave as well as particle properties. What the uncertainty principle really tells us is that if we insist on thinking of the electron as a particle, then there are certain limitations on this simplified view—namely, that the position and velocity cannot both be known precisely at the same time; and even that the electron does not *have* a precise position and momentum at the same time (because it is not simply a particle). Similarly, the energy can be uncertain in the amount ΔE for a time $\Delta t \approx \hbar / \Delta E$.

Because Planck's constant, h , is so small, the uncertainties expressed in the uncertainty principle are usually negligible on the macroscopic level. But at the level of atomic sizes, the uncertainties are significant. Because we consider ordinary objects to be made up of atoms containing nuclei and electrons, the uncertainty principle is relevant to our understanding of all of nature. The uncertainty principle expresses, perhaps most clearly, the probabilistic nature of quantum mechanics. It thus is often used as a basis for philosophic discussion.

CAUTION Uncertainties not due to instrument deficiency, but inherent in nature (wave-particle)

UNCERTAINTY PRINCIPLE $(\Delta E$ and $\Delta t)$

EXAMPLE 28-1 Position uncertainty of electron. An electron moves in a straight line with a constant speed $v = 1.10 \times 10^6$ m/s which has been measured to a precision of 0.10%. What is the maximum precision with which its position could be simultaneously measured?

APPROACH The momentum is $p = mv$, and the uncertainty in p is $\Delta p = 0.0010p$. The uncertainty principle (Eq. 28–1) gives us the lowest Δx using the equals sign.

SOLUTION The momentum of the electron is

 $p = mv = (9.11 \times 10^{-31} \text{ kg}) \cdot (1.10 \times 10^6 \text{ m/s}) = 1.00 \times 10^{-24} \text{ kg} \cdot \text{m/s}.$

The uncertainty in the momentum is 0.10% of this, or $\Delta p = 1.0 \times 10^{-27}$ kg·m/s. From the uncertainty principle, the best simultaneous position measurement will have an uncertainty of

$$
\Delta x \approx \frac{\hbar}{\Delta p} = \frac{1.06 \times 10^{-34} \,\text{J} \cdot \text{s}}{1.0 \times 10^{-27} \,\text{kg} \cdot \text{m/s}} = 1.1 \times 10^{-7} \,\text{m},
$$

or 110 nm.

NOTE This is about 1000 times the diameter of an atom.

EXERCISE A An electron's position is measured with an accuracy of 0.50×10^{-10} m. Find the minimum uncertainty in its momentum and velocity.

EXAMPLE 28-2 Position uncertainty of a baseball. What is the uncertainty in position, imposed by the uncertainty principle, on a 150-g baseball thrown at (93 ± 2) mph = (42 ± 1) m/s?

APPROACH The uncertainty in the speed is $\Delta v = 1$ m/s. We multiply Δv by m to get Δp and then use the uncertainty principle, solving for Δx .

SOLUTION The uncertainty in the momentum is

$$
\Delta p = m \Delta v = (0.150 \text{ kg})(1 \text{ m/s}) = 0.15 \text{ kg} \cdot \text{m/s}.
$$

Hence the uncertainty in a position measurement could be as small as

$$
\Delta x = \frac{\hbar}{\Delta p} = \frac{1.06 \times 10^{-34} \,\text{J} \cdot \text{s}}{0.15 \,\text{kg} \cdot \text{m/s}} = 7 \times 10^{-34} \,\text{m}.
$$

NOTE This distance is far smaller than any we could imagine observing or measuring. It is trillions of trillions of times smaller than an atom. Indeed, the uncertainty principle sets no relevant limit on measurement for macroscopic objects.

28-4 Philosophic Implications; **Probability versus Determinism**

The classical Newtonian view of the world is a deterministic one (see Section 5–9). One of its basic ideas is that once the position and velocity of an object are known at a particular time, its future position can be predicted if the forces on it are known. For example, if a stone is thrown a number of times with the same initial velocity and angle, and the forces on it remain the same, the path of the projectile will always be the same. If the forces are known (gravity and air resistance, if any), the stone's path can be precisely predicted. This mechanistic view implies that the future unfolding of the universe, assumed to be made up of particulate bodies, is completely determined.

This classical deterministic view of the physical world has been radically altered by quantum mechanics. As we saw in the analysis of the double-slit experiment (Section 28-2), electrons all released in the same way will not all end up in the same place. According to quantum mechanics, certain probabilities exist that an electron will arrive at different points. This is very different from the classical view, in which the path of a particle is precisely predictable from the initial position and velocity and the forces exerted on it. According to quantum mechanics, the position and velocity of an object cannot even be known accurately at the same time. This is expressed in the uncertainty principle, and arises because basic entities, such as electrons, are not considered simply as particles: they have wave properties as well. Quantum mechanics allows us to calculate only the probability[†] that, say, an electron (when thought of as a particle) will be observed at various places. Quantum mechanics says there is some inherent unpredictability in nature. This is very different from the deterministic view of classical mechanics.

Because matter is considered to be made up of atoms, even ordinary-sized objects are expected to be governed by probability, rather than by strict determinism. For example, quantum mechanics predicts a finite (but negligibly small) probability that when you throw a stone, its path might suddenly curve upward instead of following the downward-curved parabola of normal projectile motion. Quantum mechanics predicts with extremely high probability that ordinary objects will behave just as the classical laws of physics predict. But these predictions are considered of very high probability, not absolute certainties. The reason that macroscopic objects behave in accordance with classical laws with such high probability is due to the large number of molecules involved: when large numbers of objects are present in a statistical situation, deviations from the average (or most probable) approach zero. It is the average configuration of vast numbers of molecules that follows the so-called fixed laws of classical physics with such high probability, and gives rise to an apparent "determinism." Deviations from classical laws are observed when small numbers of molecules are dealt with. We can say, then, that although there are no precise deterministic laws in quantum mechanics, there are statistical laws based on probability.

It is important to note that there is a difference between the probability imposed by quantum mechanics and that used in the nineteenth century to understand thermodynamics and the behavior of gases in terms of molecules (Chapters 13 and 15). In thermodynamics, probability is used because there are far too many particles to keep track of. But the molecules are still assumed to move and interact in a deterministic way following Newton's laws. Probability in quantum mechanics is quite different; it is seen as *inherent* in nature, and not as a limitation on our abilities to calculate or to measure.

The view presented here is the generally accepted one and is called the Copenhagen interpretation of quantum mechanics in honor of Niels Bohr's home, since it was largely developed there through discussions between Bohr and other prominent physicists.

Because electrons are not simply particles, they cannot be thought of as following particular paths in space and time. This suggests that a description of matter in space and time may not be completely correct. This deep and far-reaching conclusion has been a lively topic of discussion among philosophers. Perhaps the most important and influential philosopher of quantum mechanics was Bohr. He argued that a space-time description of actual atoms and electrons is not possible. Yet a description of experiments on atoms or electrons must be given in terms of space and time and other concepts familiar to ordinary experience, such as waves and particles. We must not let our descriptions of experiments lead us into believing that atoms or electrons themselves actually move in space and time as classical particles.

[†]Note that these probabilities can be calculated precisely, just like exact predictions of probabilities at dice or playing cards, but unlike predictions of probabilities at sporting events or for natural or man-made disasters, which are only estimates.

Copenhagen interpretation

Probability distributions

28-5 Quantum-Mechanical View of Atoms

At the beginning of this Chapter, we discussed the limitations of the Bohr theory of atomic structure. Now we examine the quantum-mechanical theory of atoms. which is far more complete than the old Bohr theory. Although the Bohr model has been discarded as an accurate description of nature, nonetheless, quantum mechanics reaffirms certain aspects of the older theory, such as that electrons in an atom exist only in discrete states of definite energy, and that a photon of light is emitted (or absorbed) when an electron makes a transition from one state to another. But quantum mechanics is a much deeper theory, and has provided us with a very different view of the atom. According to quantum mechanics, electrons do not exist in well-defined circular orbits as in the Bohr theory. Rather, the electron (because of its wave nature) might be thought of as spread out in space as a "cloud." The size and shape of the electron cloud can be calculated for a given state of an atom. For the ground state in the hydrogen atom, the electron cloud is spherically symmetric, as shown in Fig. 28–6. The electron cloud roughly indicates the "size" of an atom. But just as a cloud may not have a distinct border, atoms do not have a precise boundary or a welldefined size. Not all electron clouds have a spherical shape, as we shall see later in this Chapter.

The electron cloud can be interpreted from either the particle or the wave viewpoint. Remember that by a particle we mean something that is localized in space—it has a definite position at any given instant. By contrast, a wave is spread out in space. The electron cloud, spread out in space as in Fig. 28-6, is a result of the wave nature of electrons. Electron clouds can also be interpreted as **probability distributions** for a particle. If you were to measure the position of an electron in a hydrogen atom 500 different times, the majority of the results would show the electron at points where the probability is high (dark area in Fig. 28–6). Only occasionally would the electron be found where the probability is low.

28-6 Quantum Mechanics of the **Hydrogen Atom; Quantum Numbers**

We now look more closely at what quantum mechanics tells us about the hydrogen atom. Much of what we say here also applies to more complex atoms, which are discussed in the next Section.

Quantum mechanics is a much more sophisticated and successful theory than Bohr's. Yet in a few details they agree. Quantum mechanics predicts the same basic energy levels (Fig. 27-27) for the hydrogen atom as does the Bohr theory. That is,

$$
E_n = -\frac{13.6 \text{ eV}}{n^2}, \qquad n = 1, 2, 3, \cdots,
$$

where n is an integer. In the simple Bohr theory, there was only one quantum number, n . In quantum mechanics, it turns out that four different quantum numbers are needed to specify each state in the atom:

- (1) The *quantum number, n*, from the Bohr theory is found also in quantum mechanics and is called the **principal quantum number**. It can have any integer value from 1 to ∞ . The total energy of a state in the hydrogen atom depends on n , as we saw above.
- (2) The orbital quantum number, l , is related to the magnitude of the angular momentum of the electron; *l* can take on integer values from 0 to $(n - 1)$. For the ground state, $n = 1$, l can only be zero.[†] For $n = 3$, l can be 0, 1, or 2.

[†]Contrast this with the Bohr theory, which assigned $l = 1$ to the ground state (Eq. 27–11).

 $0 \leq l \leq n-1$

Principal quantum number, n

Orbital quantum number, l

The actual magnitude of the angular momentum L is related to the quantum number l by

$$
L = \sqrt{l(l+1)}\hbar \tag{28-3}
$$

(where again $\hbar = h/2\pi$). The value of l has almost no effect on the total energy in the hydrogen atom; only n does to any appreciable extent (but see *fine* structure below). In atoms with two or more electrons, the energy does depend on l as well as n , as we shall see.

(3) The magnetic quantum number, m_l , is related to the *direction* of the electron's angular momentum, and it can take on integer values ranging from $-l$ to $+l$. For example, if $l = 2$, then m_l can be -2 , -1 , 0 , $+1$, or $+2$. Since angular momentum is a vector, it is not surprising that both its magnitude and its direction would be quantized. For $l = 2$, the five different directions allowed can be represented by the diagram of Fig. 28–7. This limitation on the direction of \vec{L} is often called **space quantization**. In quantum mechanics, the direction of the angular momentum is usually specified by giving its component along the z axis (this choice is arbitrary). Then L_z is related to m_l by the equation

$$
L_z = m_l \hbar.
$$

The values of L_x and L_y are not definite, however. The name for m_l derives not from theory (which relates it to L_z), but from experiment. It was found that when a gas-discharge tube was placed in a magnetic field, the spectral lines were split into several very closely spaced lines. This splitting, known as the Zeeman effect, implies that the energy levels must be split (Fig. 28–8), and thus that the energy of a state depends not only on n but also on m_l when a magnetic field is applied—hence the name "magnetic quantum number."

(4) Finally, there is the spin quantum number, m_s , which for an electron can have only two values, $m_s = +\frac{1}{2}$ and $m_s = -\frac{1}{2}$. The existence of this quantum number did not come out of Schrödinger's original theory, as did n , l , and m_l . Instead, a subsequent modification by P.A. M. Dirac (1902-1984) explained its presence as a relativistic effect. The first hint that m_s was needed, however, came from experiment. A careful study of the spectral lines of hydrogen showed that each actually consisted of two (or more) very closely spaced lines even in the absence of an external magnetic field. It was at first hypothesized that this tiny splitting of energy levels, called **fine structure**, was due to angular momentum associated with a spinning of the electron. That is, the electron might spin on its axis as well as orbit the nucleus, just as the Earth spins on its axis as it orbits the Sun. The interaction between the tiny current of the spinning electron could then interact with the magnetic field due to the orbiting charge and cause the small observed splitting of energy levels. (The energy thus depends slightly on m_l and m_s .) Today we consider this picture of a spinning electron as not legitimate. We cannot even view an electron as a localized object, much less a spinning one. What is important is that the electron can have two different states due to some intrinsic property that behaves like an angular momentum, and we still call this property "spin." The two possible values of m_s (+ $\frac{1}{2}$ and $-\frac{1}{2}$) are often said to be "spin up" and "spin down," referring to the two possible directions of the spin angular momentum.

The possible values of the four quantum numbers for an electron in the hydrogen atom are summarized in Table 28-1.

FIGURE 28-7 Quantization of angular momentum direction for $l = 2$.

Spin quantum number, m_s $m_s = +\frac{1}{2}$ or $-\frac{1}{2}$

FIGURE 28-8 When a magnetic field is applied, an $n = 3$, $l = 2$ energy level is split into five separate levels, corresponding to the five values of m_l (2, 1, 0, -1, -2). An $n = 2$, $l = 1$ level is split into three levels $(m_l = 1, 0, -1)$. Transitions can occur between levels (not all transitions are shown), with photons of several slightly different frequencies being given off (the Zeeman effect).

SECTION 28-6 Quantum Mechanics of the Hydrogen Atom; Quantum Numbers 795

CONCEPTUAL EXAMPLE 28-3 Possible states for $n = 3$. How many different states are possible for an electron whose principal quantum number is $n = 3$?

RESPONSE For $n = 3$, *l* can have the values $l = 2, 1, 0$. For $l = 2, m_l$ can be 2, 1, 0, -1, -2, which is five different possibilities. For each of these, m_s can be either up or down $\left(+\frac{1}{2}$ or $-\frac{1}{2}\right)$; so for $l = 2$, there are $2 \times 5 = 10$ states. For $l = 1$, m_l can be 1, 0, -1, and since m_s can be $+\frac{1}{2}$ or $-\frac{1}{2}$ for each of these, we have 6 more possible states. Finally, for $l = 0$, m_l can only be 0, and there are only 2 states corresponding to $m_s = +\frac{1}{2}$ and $-\frac{1}{2}$. The total number of states is $10 + 6 + 2 = 18$, as detailed in the following Table:

EXERCISE B An electron has $n = 4$, $l = 2$. Which of the following values of m_l are possible: 4, 3, 2, 1, 0, -1 , -2 , -3 , -4 ?

EXAMPLE 28-4 E and L for $n = 3$. Determine (a) the energy and (b) the orbital angular momentum for an electron in each of the hydrogen atom states of Example 28-3.

APPROACH (a) The energy of a state depends only on n , except for the very small corrections mentioned above, which we will ignore. Energy is calculated as in the Bohr theory, $E_n = -13.6 \text{ eV}/n^2$. For angular momentum we use Eq. 28–3.

SOLUTION Since $n = 3$ for all these states, they all have the same energy,

$$
E_3 = -\frac{13.6 \text{ eV}}{(3)^2} = -1.51 \text{ eV}.
$$

(*b*) For $l = 0$, Eq. 28-3 gives

$$
L=\sqrt{l(l+1)}\,\hbar=0.
$$

For $l = 1$.

$$
L = \sqrt{1(1+1)}\,\hbar = \sqrt{2}\,\hbar = 1.49 \times 10^{-34}\,\text{J} \cdot \text{s}.
$$

For $l = 2$, $L = \sqrt{2(2 + 1)} \hbar = \sqrt{6} \hbar$.

NOTE Atomic angular momenta are generally given as a multiple of \hbar ($\sqrt{2\hbar}$ or $\sqrt{6\hbar}$ in this case), rather than in SI units.

EXERCISE C What are the energy and angular momentum of the electron in a hydrogen atom with $n = 6$, $l = 4$?

Although l and m_l do not significantly affect the energy levels in hydrogen, they do affect the electron probability distribution in space. For $n = 1$, l and m_l can only be zero and the electron distribution is as shown in Fig. 28-6.

For $n = 2$, *l* can be 0 or 1. The distribution for $n = 2$, $l = 0$ is shown in Fig. 28–9a, and it is seen to differ from that for the ground state (Fig. 28–6), although it is still spherically symmetric. For $n = 2$, $l = 1$, the distributions are not spherically symmetric as shown in Figs. 28–9b (for $m_l = 0$) and 28–9c (for $m_l = +1$ or -1).

Although the spatial distributions of the electron can be calculated for the various states, it is difficult to measure them experimentally. Most of the experimental information about the atom has come from a careful examination of the emission spectra under various conditions.

$\mathrm{*}$ Selection Rules: Allowed and Forbidden Transitions

Another prediction of quantum mechanics is that when a photon is emitted or absorbed, transitions can occur only between states with values of l that differ by exactly one unit:

 $\Delta l = \pm 1.$

According to this **selection rule**, an electron in an $l = 2$ state can jump only to a state with $l = 1$ or $l = 3$. It cannot jump to a state with $l = 2$ or $l = 0$. A transition such as $l = 2$ to $l = 0$ is called a **forbidden transition**. Actually, such a transition is not absolutely forbidden and can occur, but only with very low probability compared to **allowed transitions**—those that satisfy the selection rule $\Delta l = \pm 1$. Since the orbital angular momentum of an H atom must change by one unit when it emits a photon, conservation of angular momentum tells us that the photon must carry off angular momentum. Indeed, experimental evidence of many sorts shows that the photon can be assigned a spin angular momentum of $1\hbar$.

28-7 Complex Atoms; the Exclusion Principle

We have discussed the hydrogen atom in detail because it is the simplest to deal with. Now we briefly discuss more complex atoms, those that contain more than one electron, and whose energy levels can be determined experimentally from an analysis of the emission spectra. The energy levels are not the same as in the H atom, since the electrons interact with each other as well as with the nucleus. Each electron in a complex atom still occupies a particular state characterized by the same quantum numbers n, l, m_l , and m_s . For atoms with more than one electron, the energy levels depend on both n and l .

The number of electrons in a neutral atom is called its **atomic number**, Z ; Z is also the number of positive charges (protons) in the nucleus, and determines what kind of atom it is. That is, Z determines most of the properties that distinguish one atom from another.

Quantum mechanics in the years after 1925 proved successful also in dealing with complex atoms. The mathematics becomes very difficult, however, since in multi-electron atoms, each electron is not only attracted to the nucleus but is repelled by the other electrons.

To understand the possible arrangements of electrons in an atom, a new principle was needed. It was introduced by Wolfgang Pauli (1900-1958; Fig. 28–2) and is called the **Pauli exclusion principle**. It states:

No two electrons in an atom can occupy the same quantum state.

Thus, no two electrons in an atom can have exactly the same set of the quantum numbers n, l, m_l , and m_s . The Pauli exclusion principle[†] forms the basis not only for understanding complex atoms, but also for understanding molecules and bonding, and other phenomena as well.

[†]The exclusion principle applies to identical particles whose spin quantum number is a halfinteger $(\frac{1}{2}, \frac{3}{2})$, and so on), including electrons, protons, and neutrons; such particles are called fermions (after Enrico Fermi who derived a statistical theory describing them). The exclusion principle does not apply to particles with integer spin $(0, 1, 2, 1)$ and so on), such as the photon and π meson, all of which are referred to as **bosons** (after Satyendranath Bose, who derived a statistical theory for them).

FIGURE 28-9 Electron cloud, or probability distribution, for $n = 2$ states in hydrogen.

Pauli exclusion principle

Let us now look at the structure of some of the simpler atoms when they are in the ground state. After hydrogen, the next simplest atom is helium with two electrons. Both electrons can have $n = 1$, since one can have spin up $(m_s = +\frac{1}{2})$ and the other spin down $(m_s = -\frac{1}{2})$, thus satisfying the exclusion principle. Since $n = 1$, then l and m_l must be zero (Table 28-1). Thus the two electrons have the quantum numbers indicated in the Table in the margin.

Lithium has three electrons, two of which can have $n = 1$. But the third cannot have $n = 1$ without violating the exclusion principle. Hence the third electron must have $n = 2$. It happens that the $n = 2$, $l = 0$ level has a lower energy than $n = 2$, $l = 1$, so the electrons in the ground state have the quantum numbers indicated in the Table in the margin. The quantum numbers of the third electron could also be, say, $(n, l, m_l, m_s) = (3, 1, -1, \frac{1}{2})$. But the atom in this case would be in an excited state since it would have greater energy. It would not be long before it jumped to the ground state with the emission of a photon. At room temperature, unless extra energy is supplied (as in a discharge tube), the vast majority of atoms are in the ground state.

We can continue in this way to describe the quantum numbers of each electron in the ground state of larger and larger atoms. The quantum numbers for sodium, with its eleven electrons, are shown in the Table in the margin.

Figure 28–10 shows a simple energy level diagram where occupied states are shown as up or down arrows $(m_s = +\frac{1}{2} \text{ or } -\frac{1}{2})$, and possible empty states are shown as a small circle.

The ground-state configuration for all atoms is given in the periodic table, which is displayed inside the back cover of this book, and discussed in the next Section.

 $n = 3, l = 0$ \rightarrow

28-8 The Periodic Table of Elements

More than a century ago, Dmitri Mendeleev (1834–1907) arranged the (then) known elements into what we now call the **periodic table** of the elements. The atoms were arranged according to increasing mass, but also so that elements with similar chemical properties would fall in the same column. Today's version is shown inside the back cover of this book. Each square contains the atomic number Z , the symbol for the element, and the atomic mass (in atomic mass units). Finally, the lower left corner shows the configuration of the ground state of the atom. This requires some explanation. Electrons with the same value of *n* are referred to as being in the same shell. Electrons with $n = 1$ are in one shell (the K shell), those with $n = 2$ are in a second shell (the L shell), those with $n = 3$ are in the third (M) shell, and so on. Electrons with the same values of n and l are referred to as being in the same **subshell**. Letters are often used to specify the value of l as shown in Table 28–2. That is, $l = 0$ is the s subshell; $l = 1$ is the p subshell; $l = 2$ is the d subshell; beginning with $l = 3$, the letters follow the alphabet, f, g, h, i, and so on. (The first letters s, p, d, and f were originally abbreviations of "sharp," "principal," "diffuse," and "fundamental," experimental terms referring to the spectra.)

The Pauli exclusion principle limits the number of electrons possible in each shell and subshell. For any value of *l*, there are $2l + 1$ possible m_l values $(m_l$ can be any integer from 1 to l, from -1 to $-l$, or zero), and two possible m_s values. There can be, therefore, at most $2(2l + 1)$ electrons in any *l* subshell. For example, for $l = 2$, five m_l values are possible $(2, 1, 0, -1, -2)$, and for each of these, m_s can be $+\frac{1}{2}$ or $-\frac{1}{2}$ for a total of $2(5) = 10$ states. Table 28-2 lists the maximum number of electrons that can occupy each subshell.

Since the energy levels depend almost entirely on the values of n and l , it is customary to specify the electron configuration simply by giving the n value and the appropriate letter for l , with the number of electrons in each subshell given as a superscript. The ground-state configuration of sodium, for example, is written as $1s^22s^22p^63s^1$. This is simplified in the periodic table by specifying the configuration only of the outermost electrons and any other nonfilled subshells (see Table 28–3 here, and the periodic table inside the back cover).

CONCEPTUAL EXAMPLE 28-5 Electron configurations. Which of the following electron configurations are possible, and which are not: (a) $1s^22s^22p^63s^3$; (b) $1s^22s^22p^63s^23p^54s^2$; (c) $1s^22s^22p^62d^1$?

RESPONSE (a) This is not allowed, because too many electrons (3) are shown in the s subshell of the M ($n = 3$) shell. The s subshell has $m_l = 0$, with two slots only, for "spin up" and "spin down" electrons.

 (b) This is allowed, but it is an excited state. One of the electrons from the $3p$ subshell has jumped up to the $4s$ subshell. Since there are 19 electrons, the element is potassium.

(c) This is not allowed, because there is no d ($l = 2$) subshell in the $n = 2$ shell (Table $28-1$). The outermost electron will have to be (at least) in the $n = 3$ shell.

EXERCISE D Write the complete ground-state configuration for gallium, with its 31 electrons.

The grouping of atoms in the periodic table is according to increasing atomic number, Z. There is also a strong regularity according to chemical properties. Although this is treated in chemistry textbooks, we discuss it here briefly because it is a result of quantum mechanics. See the periodic table on the inside back cover.

All the noble gases (in column VIII of the periodic table) have completely filled shells or subshells. That is, their outermost subshell is completely full, and the electron distribution is spherically symmetric. With such full spherical symmetry, other electrons are not attracted nor are electrons readily lost (ionization energy is high). This is why the noble gases are nonreactive (more on this when we discuss molecules and bonding in Chapter 29). Column VII contains the halogens, which lack one electron from a filled shell. Because of the shapes of the orbits (see Section 29–1), an additional electron can be accepted from another atom, and hence these elements are quite reactive. They have a valence of -1 , meaning that when an extra electron is acquired, the resulting ion has a net charge of $-i$ e. Column I of the periodic table contains the **alkali metals**, all of which have a single outer s electron. This electron spends most of its time outside the inner closed shells and subshells which shield it from most of the nuclear charge. Indeed, it is relatively far from the nucleus and is attracted to it by a net charge of only about $+1e$, because of the shielding effect of the other electrons. Hence this outer electron is easily removed and can spend much of its time around another atom, forming a molecule. This is why the alkali metals are highly reactive and have a valence of $+1$. The other columns of the periodic table can be treated similarly.

TABLE 28-3 Electron Configuration of Some Elements

[†]Names of elements can be found in Appendix B.

CAUTION Subshells are not always filled in "order"

The presence of the **transition elements** in the center of the table, as well as the lanthanides (rare earths) and actinides below, is a result of incomplete inner shells. For the lowest Z elements, the subshells are filled in a simple order: first 1s, then 2s, followed by 2p, 3s, and 3p. You might expect that 3d ($n = 3$, $l = 2$) would be filled next, but it isn't. Instead, the 4s level actually has a slightly lower energy than the 3d (due to electrons interacting with each other), so it fills first (K and Ca). Only then does the 3d shell start to fill up, beginning with Sc, as can be seen in Table $28-3$. (The 4s and 3d levels are close, so some elements have only one 4s electron, such as Cr.) Most of the chemical properties of these transition elements are governed by the relatively loosely held 4s electrons, and hence they usually have valences of $+1$ or $+2$. A similar effect is responsible for the lanthanides and actinides, which are shown at the bottom of the periodic table for convenience. All have very similar chemical properties, which are determined by their two outer 6s or 7s electrons, whereas the different numbers of electrons in the unfilled inner shells have little effect.

28-9 X-Ray Spectra and Atomic Number

The line spectra of atoms in the visible, UV, and IR regions of the EM spectrum are mainly due to transitions between states of the outer electrons. Much of the charge of the nucleus is shielded from these electrons by the negative charge on the inner electrons. But the innermost electrons in the $n = 1$ shell "see" the full charge of the nucleus. Since the energy of a level is proportional to Z^2 (see Eq. 27–15), for an atom with $Z = 50$, we would expect wavelengths about $50^2 = 2500$ times shorter than those found in the Lyman series of hydrogen (around 100 nm), or 10^{-2} to 10^{-1} nm. Such short wavelengths lie in the X-ray region of the spectrum.

FIGURE 28-11 Spectrum of X-rays emitted from a molybdenum target in an X-ray tube operated at 50 kV.

X-rays are produced when electrons accelerated by a high voltage strike the metal target inside the X-ray tube (Section $25-11$). If we look at the spectrum of wavelengths emitted by an X-ray tube, we see that the spectrum consists of two parts: a continuous spectrum with a cutoff at some λ_0 which depends only on the voltage across the tube, and a series of peaks superimposed. A typical example is shown in Fig. 28–11. The smooth curve and the cutoff wavelength λ_0 move to the left as the voltage across the tube increases. The sharp lines or peaks (labeled K_{α} and K_{β} in Fig. 28–11), however, remain at the same wavelength when the voltage is changed, although they are located at different wavelengths when different target materials are used. This observation suggests that the peaks are characteristic of the material used. Indeed, we can explain them by imagining that the electrons accelerated by the high voltage of the tube can reach sufficient energies that when they collide with the atoms of the target, they can knock out one of the very tightly held inner electrons. Then we explain these **characteristic** X-rays (the peaks in Fig. 28-11) as photons emitted when an electron in an upper state drops down to fill the vacated lower state. The K lines result from transitions *into* the K shell ($n = 1$). The K_a line consists of photons emitted in a transition that originates from the $n = 2$ (L) shell and drops to the $n = 1$ (K) shell, whereas the K_B line reflects a transition from the $n = 3$ (M) shell down to the K shell. An L line is due to a transition into the L shell, and so on.

Characteristic X-rays

Measurement of the characteristic X-ray spectra has allowed a determination of the inner energy levels of atoms. It has also allowed the determination of Z values for many atoms, since (as we have seen) the wavelength of the shortest X-rays emitted will be inversely proportional to Z^2 . Actually, for an electron jumping from, say, the $n = 2$ to the $n = 1$ level, the wavelength is inversely proportional to $(Z - 1)^2$ because the nucleus is shielded by the one electron that still remains in the 1s level. In 1914, H. G. J. Moseley (1887–1915) found that a plot of $\sqrt{1/\lambda}$ versus Z produced a straight line, Fig. 28–12. The Z values of a number of elements were determined by fitting them to such a **Moseley plot**. The work of Moseley put the concept of atomic number on a firm experimental basis.

FIGURE 28-12 Plot of $\sqrt{1/\lambda}$ vs. Z for K_{α} X-ray lines.

EXAMPLE 28-6 X-ray wavelength. Estimate the wavelength for an $n = 2$ to $n = 1$ transition in molybdenum (Z = 42). What is the energy of such a photon?

APPROACH We use the Bohr formula, Eq. 27–16 for $1/\lambda$, with Z^2 replaced by $(Z-1)^2 = (41)^2$.

SOLUTION Equation 27-16 gives

$$
\frac{1}{\lambda} = \left(\frac{2\pi^2 e^4 m k^2}{h^3 c}\right) (Z - 1)^2 \left(\frac{1}{n^2} - \frac{1}{n^2}\right)
$$

where $n = 2$ and $n' = 1$. We substitute in values:

$$
\frac{1}{\lambda} = (1.097 \times 10^{7} \,\text{m}^{-1})(41)^{2} \left(\frac{1}{1} - \frac{1}{4}\right)
$$

$$
= 1.38 \times 10^{10} \,\text{m}^{-1}.
$$

So $\lambda = 0.072$ nm. This is close to the measured value (Fig. 28–11) of 0.071 nm. Each of these photons would have energy (in eV) of:

$$
E = hf = \frac{hc}{\lambda} = \frac{(6.63 \times 10^{-34} \,\text{J} \cdot \text{s})(3.00 \times 10^8 \,\text{m/s})}{(7.2 \times 10^{-11} \,\text{m})(1.60 \times 10^{-19} \,\text{J/eV})} = 17 \,\text{keV}.
$$

The denominator includes the conversion factor from joules to eV.

EXAMPLE 28-7 Determining atomic number. High-energy photons are used to bombard an unknown material. The strongest peak is found for X-rays emitted with an energy of 66 keV. Guess what the material is.

APPROACH The highest intensity X-rays are generally for the K_a line (see Fig. $28-11$) which occurs when photons knock out K shell electrons (the innermost orbit, $n = 1$) and their place is taken by electrons from the L shell $(n = 2)$. We use the Bohr model, and assume the electrons "see" a nuclear charge of $Z - 1$ (screened by one electron) instead of $Z = 1$.

SOLUTION The hydrogen transition $n = 2$ to $n = 1$ would yield about 10.2 eV (see Fig. 27–27 or Example 27–12). Energy E is proportional to Z^2 (Eq. 27–15), or rather $(Z - 1)^2$ because the nucleus is shielded by the one electron in a 1s state (see above), so we can use ratios:

$$
\frac{(Z-1)^2}{1^2} = \frac{66 \times 10^3 \text{ eV}}{10.2 \text{ eV}} = 6.5 \times 10^3,
$$

so $Z - 1 = \sqrt{6500} = 81$, and $Z = 82$, which makes it lead.

FIGURE 28-11 (repeated) Spectrum of X-rays emitted from a molybdenum target in an X-ray tube operated at 50 kV.

FIGURE 28-13 Bremsstrahlung photon produced by an electron decelerated by interaction with a target atom.

Now we briefly analyze the continuous part of an X-ray spectrum (Fig. 28–11) based on the photon theory of light. When electrons strike the target, they collide with atoms of the material and give up most of their energy as heat (about 99%, so X-ray tubes must be cooled). Electrons can also give up energy by emitting a photon of light: an electron decelerated by interaction with atoms of the target (Fig. $28-13$) emits radiation because of its deceleration (Chapter 22), and in this case it is called **bremsstrahlung** (German for "braking") radiation"). Because energy is conserved, the energy of the emitted photon, hf , must equal the loss of kinetic energy of the electron, $\Delta KE = KE - KE'$, so

 $hf = \Delta$ KE.

An electron may lose all or a part of its energy in such a collision. The continuous X-ray spectrum (Fig. 28–11) is explained as being due to such bremsstrahlung collisions in which varying amounts of energy are lost by the electrons. The shortest-wavelength X-ray (the highest frequency) must be due to an electron that gives up all its kinetic energy to produce one photon in a single collision. Since the initial kinetic energy of an electron is equal to the energy given it by the accelerating voltage, V, then $KE = eV$. In a single collision in which the electron is brought to rest ($KE' = 0$), then $\Delta KE = eV$ and

$$
hf_0 = eV
$$
.

We set $f_0 = c/\lambda_0$ where λ_0 is the cutoff wavelength (Fig. 28–11) and find

$$
\lambda_0 = \frac{hc}{eV} \tag{28-4}
$$

This prediction for λ_0 corresponds precisely with that observed experimentally. This result is further evidence that X-rays are a form of electromagnetic radiation (light) and that the photon theory of light is valid.

EXAMPLE 28-8 Cutoff wavelength. What is the shortest-wavelength X-ray photon emitted in an X-ray tube subjected to 50 kV?

APPROACH The electrons striking the target will have a KE of 50 keV. The shortest-wavelength photons are due to collisions in which all of the electron's KE is given to the photon so $KE = eV = hf_0$.

SOLUTION From Eq. 28-4,

$$
\lambda_0 = \frac{hc}{eV} = \frac{(6.63 \times 10^{-34} \,\text{J} \cdot \text{s})(3.0 \times 10^8 \,\text{m/s})}{(1.6 \times 10^{-19} \,\text{C})(5.0 \times 10^4 \,\text{V})} = 2.5 \times 10^{-11} \,\text{m},
$$

or 0.025 nm.

NOTE This result agrees well with experiment, Fig. 28–11.

PHYSICS **APPLIED** Fluorescence analysis and fluorescent lightbulbs

28-10 Fluorescence and Phosphorescence

When an atom is excited from one energy state to a higher one by the absorption of a photon, it may return to the lower level in a series of two (or more) jumps if there is an energy level in between (Fig. 28-14). The photons emitted will consequently have lower energy and frequency than the absorbed photon. When the absorbed photon is in the UV and the emitted photons are in the visible region of the spectrum, this phenomenon is called fluorescence (Fig. $28-15$).

The wavelength for which fluorescence will occur depends on the energy levels of the particular atoms. Because the frequencies are different for different
substances, and because many substances fluoresce readily, fluorescence is a powerful tool for identification of compounds. It is also used for assayingdetermining how much of a substance is present—and for following substances along a natural metabolic pathway in plants or animals. For detection of a given compound, the stimulating light must be monochromatic, and solvents or other materials present must not fluoresce in the same region of the spectrum. Sometimes the direct observation of fluorescent light being emitted is sufficient to detect a compound. In other cases, spectrometers are used to measure the wavelengths and intensities of the emitted light.

Fluorescent lightbulbs work in a two-step process. The applied voltage accelerates electrons that strike atoms of the gas in the tube and cause them to be excited. When the excited atoms jump down to their normal levels, they emit UV photons which strike a fluorescent coating on the inside of the tube. The light we see is a result of this material fluorescing in response to the UV light striking it.

Materials such as those used for luminous watch dials are said to be phosphorescent. When an atom is raised to a normal excited state, it drops back down within about 10^{-8} s. In phosphorescent substances, atoms can be excited by photon absorption to energy levels called metastable, which are states that last much longer—even a few seconds or longer. In a collection of such atoms, many of the atoms will descend to the lower state fairly soon, but many will remain in the excited state for over an hour. Hence light will be emitted even after long periods. When you put your watch dial close to a bright lamp, it excites many atoms to metastable states, and you can see the glow a long time after.

FIGURE 28-15 When UV light illuminates these rocks, they fluoresce in the visible region of the spectrum.

28-11 Lasers

A laser is a device that can produce a very narrow intense beam of monochromatic coherent light. (By *coherent*, we mean that across any cross section of the beam, all parts have the same phase.) The emitted beam is a nearly perfect plane wave. An ordinary light source, on the other hand, emits light in all directions (so the intensity decreases rapidly with distance), and the emitted light is incoherent (the different parts of the beam are not in phase with each other). The excited atoms that emit the light in an ordinary lightbulb act independently, so each photon emitted can be considered as a short wave train, typically 30 cm long and lasting 10^{-8} s. These wave trains bear no phase relation to one another. Just the opposite is true of lasers.

The action of a laser is based on quantum theory. We have seen that a photon can be absorbed by an atom if (and only if) its energy hf corresponds to the energy difference between an occupied energy level of the atom and an available excited state, Fig. 28-16a. If the atom is already in the excited state, it may jump spontaneously (i.e., no stimulus) to the lower state with the emission of a photon. However, if a photon with this same energy strikes the excited atom, it can stimulate the atom to make the transition sooner to the lower state, Fig. 28–16b. This phenomenon is called **stimulated emission**: not only do we still have the original photon, but also a second one of the same frequency as a result of the atom's transition. These two photons are exactly in phase, and they are moving in the same direction. This is how coherent light is produced in a laser. Hence the name laser, which is an acronym for light amplification by stimulated emission of radiation.

Normally, most atoms are in the lower state, so the majority of incident photons will be absorbed. To obtain the coherent light from stimulated emission, two conditions must be satisfied. First, the atoms must be excited to the higher state so that an **inverted population** is produced, one in which more atoms are in the upper state than in the lower one (Fig. 28–17). Then *emission* of photons will dominate over absorption. And second, the higher state must be a metastable state—a state in which the electrons remain longer than usual^{\dagger} so that the transition to the lower state occurs by stimulated emission rather than spontaneously.

[†]An excited atom may land in such a state and can jump to a lower state only by a so-called forbidden transition (discussed in Section 28-6), which is why its lifetime is longer than normal.

FIGURE 28-16 (a) Absorption of a photon. (b) Stimulated emission. E_u and E_l refer to "upper" and "lower" energy states.

Stimulated emission

FIGURE 28-17 Two energy levels for a collection of atoms. Each dot represents the energy state of one atom. (a) A normal situation; (b) an inverted population.

FIGURE 28-18 Laser diagram, showing excited atoms stimulated to emit light.

Figure 28–18 is a schematic diagram of a laser: the "lasing" material is placed in a long narrow tube at the ends of which are two mirrors, one of which is partially transparent (transmitting perhaps 1 or 2%). Some of the excited atoms drop down fairly soon after being excited. One of these is the blue atom shown on the far left in Fig. 28–18. If the emitted photon strikes another atom in the excited state, it stimulates this atom to emit a photon of the same frequency, moving in the same direction, and in phase with it. These two photons then move on to strike other atoms causing more stimulated emission. As the process continues, the number of photons multiplies. When the photons strike the end mirrors, most are reflected back, and as they move in the opposite direction, they continue to stimulate more atoms to emit photons. As the photons move back and forth between the mirrors, a small percentage passes through the partially transparent mirror at one end. These photons make up the narrow[†] coherent external laser beam.

In a well-designed laser, the spreading of the beam is limited only by diffraction, so the angular spread is $\approx \lambda/D$ (see Eq. 24–3 or 25–7) where D is the diameter of the end mirror. The diffraction spreading can be incredibly small. The light energy, instead of spreading out in space as it does for an ordinary light source, is directed in a pencil-thin beam.

* Creating an Inverted Population

Ruby laser

The excitation of the atoms in a laser can be done in several ways to produce the necessary inverted population. In a ruby laser, the lasing material is a ruby rod consisting of $A_1 O_3$ with a small percentage of aluminum (Al) atoms replaced by chromium (Cr) atoms. The Cr atoms are the ones involved in lasing. In a process called **optical pumping**, the atoms are excited by strong flashes of light of wavelength 550 nm, which corresponds to a photon energy of 2.2 eV . As shown in Fig. 28–19, the atoms are excited from state E_0 to state E_2 . The atoms quickly decay either back to E_0 or to the intermediate state E_1 , which is metastable with a lifetime of about 3×10^{-3} s (compared to 10^{-8} s for ordinary levels). With strong pumping action, more atoms can be found in the E_1 state than are in the E_0 state. Thus we have the inverted population needed for lasing. As soon as a few atoms in the E_1 state jump down to E_0 , they emit photons that produce stimulated emission of the other atoms, and the lasing action begins. A ruby laser thus emits a beam whose photons have energy 1.8 eV and a wavelength of 694.3 nm (or "ruby-red" light).

[†]Inside the tube, some spontaneously emitted photons will be emitted at an angle to the axis, and these will merely go out the side of the tube and not affect the narrowness of the main beam.

FIGURE 28-19 Energy levels of chromium in a ruby crystal. Photons of energy 2.2 eV "pump" atoms from E_0 to E_2 , which then decay to metastable state E_1 . Lasing action occurs by stimulated emission of photons in transition from E_1 to E_0 .

He-Ne laser

In a helium-neon (He-Ne) laser, the lasing material is a gas, a mixture of about 85% He and 15% Ne. The atoms are excited by applying a high voltage to the tube so that an electric discharge takes place within the gas. In the process, some of the He atoms are raised to the metastable state E_1 shown in Fig. 28–20, which corresponds to a jump of 20.61 eV, almost exactly equal to an excited state in neon, 20.66 eV. The He atoms do not quickly return to the ground state by spontaneous emission, but instead often give their excess energy to a Ne atom when they collide—see Fig. 28–20. In such a collision, the He drops to the ground state and the Ne atom is excited to the state E'_{3} (the prime refers to neon states). The slight difference in energy (0.05 eV) is supplied by the kinetic energy of the moving atoms. In this manner, the E'_3 state in Ne—which is metastable—becomes more populated than the E'_2 level. This inverted population between E'_3 and E'_2 is what is needed for lasing.

FIGURE 28-20 Energy levels for He and Ne. He is excited in the electric discharge to the E_1 state. This energy is transferred to the E'_3 level of the Ne by collision. E'_3 is metastable and decays to E'_2 by stimulated emission.

Other types of laser include: chemical lasers, in which the energy input comes from the chemical reaction of highly reactive gases; dye lasers, whose frequency is tunable; $CO₂$ gas lasers, capable of high power output in the infrared; rare-earth solid-state lasers such as the high-power Nd:YAG laser; and the semiconductor diode laser, also called pn junction laser, in which the transitions occur between the bottom of the conduction band and the upper part of the valence band (Section 29-6). CD and DVD players (see below) use semiconductor lasers.

The excitation of the atoms in a laser can be done continuously or in pulses. In a **pulsed laser**, the atoms are excited by periodic inputs of energy. In a **continuous laser**, the energy input is continuous: as atoms are stimulated to jump down to the lower level, they are soon excited back up to the upper level so the output is a continuous laser beam. No laser is a source of energy. Energy must be put in, and the laser converts a part of it into an intense narrow beam output.

* Applications

The unique feature of light from a laser, that it is a coherent narrow beam, has found many applications. Lasers are a useful surgical tool. The narrow intense beam can be used to destroy tissue in a localized area, or to break up gallstones and kidney stones. Because of the heat produced, a laser beam can be used to "weld" broken tissue, such as a detached retina. The laser beam can be carried by an optical fiber (Section 23–6) to the surgical point, sometimes as an additional fiber-optic path on an endoscope, Fig. 28-21 (see also Section 23-6). An example is the removal of plaque clogging human arteries. Tiny organelles within a living cell have been destroyed using lasers by researchers studying how the absence of that organelle affects the behavior of the cell. Laser beams are used to destroy cancerous and precancerous cells; and the heat seals off capillaries and lymph vessels, thus "cauterizing" the wound to prevent spread of the disease.

The intense heat produced in a small area by a laser beam is used for welding and machining metals and for drilling tiny holes in hard materials. Because a laser beam is coherent, monochromatic, narrow, and essentially parallel, lenses can be used to focus the light into even smaller areas. The precise straightness of a laser beam is also useful to surveyors for lining up equipment accurately, especially in inaccessible places.

 dve

Other lasers: chemical

FIGURE 28-21 Laser being used in eye surgery.

FIGURE 28–22 (a) Reading a CD (or DVD). The fine beam of a laser, focused even more finely with lenses, is directed at the undersurface of a rotating compact disk. The beam is reflected back from the areas between pits but reflects much less from pits. The reflected light is detected as shown, reflected by a half-reflecting mirror MS. The strong and weak reflections correspond to the 0s and 1s of the binary code representing the audio or video signal. (b) A laser follows the CD track which starts near the center and spirals outward.

 $\left(\uparrow\right)$ PHYSICS APPLIED DVD and CD players, bar codes

In everyday life, lasers are used as bar-code readers (at store checkout stands) and in compact disc (CD) and digital video disc (DVD) players. The laser beam reflects off the stripes and spaces of a bar code, and off the tiny pits of a CD or DVD as shown in Fig. 28-22a. The recorded information on a CD or DVD is a series of pits and spaces representing 0s and 1s (or "off" and "on") of a digitized code that is decoded electronically before being sent to the audio or video system. The laser of a CD player starts reading at the inside of the disc which rotates at about 500 rpm at the start. As the disc rotates, the laser follows the spiral track (Fig. 28–22b), and as it moves outward the disc must slow down because each successive circumference $(C = 2\pi r)$ is slightly longer as r increases; at the outer edge, the disc is rotating about 200 rpm. A 1-hour CD has a track roughly 5 km long; the track width is about 1600 nm (= $1.6 \mu m$) and the distance between pits is about 800 nm. DVDs contain much more information. They are based on more recent technology and can use a thinner track $(0.7 \mu m)$ and shorter pit length (400 nm, these numbers being for a standard DVD). New versions use a "blue" laser with a shorter wavelength (405 nm) and narrower beam, allowing a narrower track (0.3 μ m) that can store much more data for high definition. DVDs can also have two layers, one below the other. When the laser focuses on the second layer, the light passes through the semitransparent surface layer. The second layer may start reading at the outer edge instead of inside. DVDs can also have a single or double layer on *both* surfaces of the disc.

28-12 Holography

Holography

One of the most interesting applications of laser light is the production of three-dimensional images called holograms (see Fig. 28-23.) In an ordinary photograph, the film simply records the intensity of light reaching it at each point. When the photograph or transparency is viewed, light reflecting from it or passing through it gives us a two-dimensional picture. In holography, the images are formed by interference, without lenses. When a laser hologram is made on film, a broadened laser beam is split into two parts by a half-silvered mirror, Fig. 28–23a. One part goes directly to the film; the rest passes to the object to be photographed, from which it is reflected to the film. Light from every point on the object reaches each point on the film, and the interference of the two beams allows the film to record both the intensity and relative phase of the light at each point. It is crucial that the light be coherent—that is, in phase at all points—which is why a laser is used. After the film is developed, it is placed

FIGURE 28-23 (a) Making a hologram. Light reflected from various points on the object interferes (at the film) with light from the direct beam. (b) A boy is looking at a hologram of two women talking on telephones.

again in a laser beam and a three-dimensional image of the object is created. You can walk around such an image and see it from different sides as if it were the original object (Fig. 28–23b). Yet, if you try to touch it with your hand, there will be nothing material there.

Volume or white-light holograms do not require a laser to see the image, but can be viewed with ordinary white light (preferably a nearly point source, such as the Sun or a clear bulb with a small bright filament). Such holograms must be made, however, with a laser. They are made not on thin film, but on a *thick* emulsion. The interference pattern in the film emulsion can be thought of as an array of bands or ribbons where constructive interference occurred. This array, and the reconstruction of the image, can be compared to Bragg scattering of X-rays from the atoms in a crystal (see Section 25–11). White light can reconstruct the image because the Bragg condition $(m\lambda = 2d \sin \theta)$ selects out the appropriate single wavelength. If the hologram is originally produced by lasers emitting the three additive primary colors (red, green, and blue), the three-dimensional image can be seen in full color when viewed with white light.

White-light holograms

Summary

In 1925, Schrödinger and Heisenberg separately worked out a new theory, quantum mechanics, which is now considered to be the basic theory at the atomic level. It is a statistical theory rather than a deterministic one.

An important aspect of quantum mechanics is the Heisenberg uncertainty principle. It results from the wave-particle duality and the unavoidable interaction between an observed object and the observer.

One form of the uncertainty principle states that the position x and momentum p_x of an object cannot both be measured precisely at the same time. The products of the uncertainties, $(\Delta x)(\Delta p_x)$, can be no less than \hbar (= $h/2\pi$):

$$
(\Delta p_x)(\Delta x) \gtrsim \hbar. \tag{28-1}
$$

Another form of the uncertainty principle states that the energy can be uncertain by an amount ΔE for a time Δt , where

$$
\Delta E)(\Delta t) \gtrsim \hbar. \tag{28-2}
$$

According to quantum mechanics, the state of an electron in an atom is specified by four **quantum numbers**: n, l, m_l , and m_s :

- (1) n , the **principal quantum number**, can take on any integer value $(1, 2, 3, \dots)$ and corresponds to the quantum number of the old Bohr theory;
- (2) l , the **orbital quantum number**, can take on values from 0 up to $n-1$;
- (3) m_l , the **magnetic quantum number**, can take on integer values from $-l$ to $+l$;
- (4) m_s , the spin quantum number, can be $+\frac{1}{2}$ or $-\frac{1}{2}$.

The energy levels in the hydrogen atom depend on n , whereas in other atoms they depend on n and l .

When an external magnetic field is applied, the spectral lines are split (the Zeeman effect), indicating that the energy depends also on m_l in this case.

Even in the absence of a magnetic field, precise measurements of spectral lines show a tiny splitting of the lines called fine structure, whose explanation is that the energy depends very slightly on m_l and m_s .

[*Transitions between states that obey the selection rule $\Delta l = \pm 1$ are far more probable than other so-called "forbidden" transitions.]

The arrangement of electrons in multi-electron atoms is governed by the Pauli exclusion principle, which states that no two electrons can occupy the same quantum state—that is, they cannot have the same set of quantum numbers n, l, m_l , and m_s .

As a result, electrons in multi-electron atoms are grouped into shells (according to the value of n) and subshells (according to l).

Electron configurations are specified using the numerical values of n , and using letters for $l: s, p, d, f$, etc., for $l = 0, 1, 2, 3$, and so on, plus a superscript for the number of electrons in that subshell. Thus, the ground state of hydrogen is 1s¹, whereas that for oxygen is $1s^22s^22p^4$.

The periodic table arranges the elements in horizontal rows according to increasing atomic number (number of electrons in the neutral atom). The shell structure gives rise to a periodicity in the properties of the elements, so that each vertical column can contain elements with similar chemical properties.

X-rays, which are a form of electromagnetic radiation of very short wavelength, are produced when high-speed electrons strike a target. The spectrum of X-rays so produced consists of two parts, a continuous spectrum produced when the electrons are decelerated by atoms of the target, and peaks representing photons emitted by atoms of the target after being excited by collision with the high-speed electrons. Measurement of these peaks allows determination of inner energy levels of atoms and determination of Z.

[*Fluorescence occurs when absorbed UV photons are followed by emission of visible light, due to the special arrangement of energy levels of the material. Phosphorescent materials have metastable states (long-lived) that emit light seconds or minutes after absorption of light.]

[*Lasers produce a narrow beam of monochromatic coherent light (light waves in phase). Holograms are images with a 3-dimensional quality, formed by interference of laser light.]

Questions

- **1.** Compare a matter wave Ψ to (*a*) a wave on a string, (b) an EM wave. Discuss similarities and differences.
- 2. Explain why Bohr's theory of the atom is not compatible with quantum mechanics, particularly the uncertainty principle.
- 3. Explain why it is that the more massive an object is, the easier it becomes to predict its future position.
- 4. In view of the uncertainty principle, why does a baseball seem to have a well-defined position and speed whereas an electron does not?
- 5. Would it ever be possible to balance a very sharp needle precisely on its point? Explain.
- 6. A cold thermometer is placed in a hot bowl of soup. Will the temperature reading of the thermometer be the same as the temperature of the hot soup before the measurement was made? Explain.
- 7. Does the uncertainty principle set a limit to how well you can make any single measurement of position?
- 8. If you knew the position of an object precisely, with no uncertainty, how well would you know its momentum?
- 9. When you check the pressure in a tire, doesn't some air inevitably escape? Is it possible to avoid this escape of air altogether? What is the relation to the uncertainty principle?
- 10. It has been said that the ground-state energy in the hydrogen atom can be precisely known but the excited states have some uncertainty in their values (an "energy width"). Is this consistent with the uncertainty principle in its energy form? Explain.
- 11. Which model of the hydrogen atom, the Bohr model or the quantum-mechanical model, predicts that the electron spends more time near the nucleus?
- 12. The size of atoms varies by only a factor of three or so, from largest to smallest, yet the number of electrons varies from one to over 100. Explain.
- 13. Excited hydrogen and excited helium atoms both radiate light as they jump down to the $n = 1$, $l = 0$, $m_l = 0$ state. Yet the two elements have very different emission spectra. Why?
- 14. How would the periodic table look if there were no electron spin but otherwise quantum mechanics were valid? Consider the first 20 elements or so.
- 15. Which of the following electron configurations are not allowed: (a) $1s^22s^22p^43s^24p^2$; (b) $1s^22s^22p^83s^1$; (c) $1s^2 2s^2 2p^6 3s^2 3p^5 4s^2 4d^5 4f^1$? If not allowed, explain why.
- 16. Give the complete electron configuration for a uranium atom (careful scrutiny across the periodic table on the inside back cover will provide useful hints).
- 17. In what column of the periodic table would you expect to find the atom with each of the following configurations: (a) $1s^22s^22p^63s^2$; (b) $1s^22s^22p^63s^23p^6$; (c) $1s^22s^22p^63s^23p^64s^1$; (d) $1s^22s^22p^5$?
- 18. Why do chlorine and iodine exhibit similar properties?
- 19. Explain why potassium and sodium exhibit similar properties.
- **20.** The ionization energy for neon $(Z = 10)$ is 21.6 eV, and that for sodium $(Z = 11)$ is 5.1 eV. Explain the large difference.
- *21. Why does the cutoff wavelength in Fig. 28-11 imply a photon nature for light?
- *22. Why do we not expect perfect agreement between measured values of X-ray line wavelengths and those calculated using Bohr theory, as in Example 28-6?
- * 23. How would you figure out which lines in an X-ray spectrum correspond to K_{α} , K_{β} , L etc., transitions?
- 24. Why do we expect electron transitions deep within an atom to produce shorter wavelengths than transitions by outer electrons?
- * 25. Compare spontaneous emission to stimulated emission.
- * 26. How does laser light differ from ordinary light? How is it the same?

Problems

28-2 Wave Function, Double-Slit

- 1. (II) The neutrons in a parallel beam, each having kinetic energy $\frac{1}{40}$ eV, are directed through two slits 0.50 mm apart. How far apart will the interference peaks be on a screen 1.0 m away? [Hint: first find the wavelength of the neutron.
- 2. (II) Bullets of mass 3.0 g are fired in parallel paths with speeds of 220 m/s through a hole 3.0 mm in diameter. How far from the hole must you be to detect a 1.0-cmdiameter spread in the beam of bullets?

28-3 Uncertainty Principle

- 3. (I) A proton is traveling with a speed of $(6.560 \pm 0.012) \times 10^5$ m/s. With what maximum accuracy can its position be ascertained? [*Hint*: $\Delta p = m \Delta v$.]
- 4. (I) If an electron's position can be measured to an accuracy of 2.0×10^{-8} m, how accurately can its speed be known?
- 5. (I) An electron remains in an excited state of an atom for typically 10^{-8} s. What is the minimum uncertainty in the energy of the state (in eV)?
- 6. (I) The Z^0 boson, discovered in 1985, is the mediator of the weak nuclear force, and it typically decays very quickly. Its average rest energy is 91.19 GeV, but its short lifetime shows up as an intrinsic width of 2.5 GeV (rest energy uncertainty). What is the lifetime of this particle?
- 7. (II) What is the uncertainty in the mass of a muon $(m = 105.7 \text{ MeV}/c^2)$, specified in eV/c², given its lifetime of 2.20 μ s? [*Hint*: $\Delta E \approx \hbar / \Delta t$.]
- 8. (II) A free neutron $(m = 1.67 \times 10^{-27} \text{ kg})$ has a mean life of 900 s. What is the uncertainty in its mass (in kg)?
- 9. (II) An electron and a 140-g baseball are each traveling 150 m/s measured to an accuracy of 0.055%. Calculate and compare the uncertainty in position of each.
- 10. (III) Estimate the lowest possible energy of a neutron contained in a typical nucleus of radius 1.0×10^{-15} m. [Hint: a particle can have an energy at least as large as its uncertainty.]
- 11. (III) Use the uncertainty principle to show that if an electron were present in the nucleus $(r \approx 10^{-15}m)$, its kinetic energy (use relativity) would be hundreds of MeV. (Since such electron energies are not observed, we conclude that electrons are not present in the nucleus.) [$Hint$: a particle can have an energy at least as large as its uncertainty.]
- 12. (III) How accurately can the position of a 3.00 -keV electron be measured assuming its energy is known to 1.00%?
- * 27. Explain how a 0.0005-W laser beam, photographed at a distance, can seem much stronger than a 1000-W street lamp at the same distance.
- * 28. Does the intensity of light from a laser fall off as the inverse square of the distance? Explain.

28-6 to 28-8 Quantum Numbers, Exclusion Principle

- 13. (I) For $n = 6$, what values can *l* have?
- **14.** (I) For $n = 5$, $l = 3$, what are the possible values of m_l and m_s ?
- 15. (I) How many electrons can be in the $n = 6$, $l = 3$ subshell?
- **16.** (I) How many different states are possible for an electron whose principal quantum number is $n = 4$? Write down the quantum numbers for each state.
- 17. (I) List the quantum numbers for each electron in the ground state of (a) carbon $(Z = 6)$, (b) magnesium $(Z = 12)$.
- 18. (I) List the quantum numbers for each electron in the ground state of nitrogen $(Z = 7)$.
- **19.** (I) Suppose a certain hydrogen atom has $l = 4$. What are the possible values for *n*, m_l , and m_s ?
- 20. (I) Calculate the magnitude of the angular momentum of an electron in the $n = 4$, $l = 3$ state of hydrogen.
- 21. (II) If a hydrogen atom has $m_l = -3$, what are the possible values of *n*, *l*, and m_s ?
- 22. (II) Show that there can be 18 electrons in a " g " subshell.
- 23. (II) What is the full electron configuration in the ground state for elements with Z equal to (a) 27, (b) 36, (c) 38? [*Hint*: see the periodic table inside the back cover.]
- 24. (II) What is the full electron configuration for (a) selenium (Se), (b) gold (Au), (c) radium (Ra)? [Hint: see the periodic table inside the back cover.]
- 25. (II) A hydrogen atom is in the 6s state. Determine (a) the principal quantum number, (b) the energy of the state, (c) the orbital angular momentum and its quantum number l , and (d) the possible values for the magnetic quantum number.
- 26. (II) Estimate the binding energy of the third electron in lithium using the Bohr theory. [Hint: this electron has $n = 2$ and "sees" a net charge of approximately +1e.] The measured value is 5.36 eV.
- $27.$ (II) Show that the total angular momentum is zero for a filled subshell.
- * 28. (II) For each of the following atomic transitions, state whether the transition is allowed or forbidden, and if forbidden, what rule is being violated: (a) $4p \rightarrow 3p$; (b) $2p \rightarrow 1s$; (c) $3d \rightarrow 2d$; (d) $4d \rightarrow 3s$; (e) $4s \rightarrow 2p$.

* 29. (II) An excited H atom is in a 6d state. (a) Name all the states (n, l) to which the atom is "allowed" to jump with the emission of a photon. (b) How many different wavelengths are there (ignoring fine structure)?

* 28-9 X-Rays

- * 30. (I) What are the shortest-wavelength X-rays emitted by electrons striking the face of a 33.5-kV TV picture tube? What are the longest wavelengths?
- *31. (I) If the shortest-wavelength bremsstrahlung X-rays emitted from an X-ray tube have $\lambda = 0.030$ nm, what is the voltage across the tube?
- * 32. (I) Show that the cutoff wavelength λ_0 is given by

$$
\lambda_0 = \frac{1240 \text{ nm}}{V}
$$

where V is the X-ray tube voltage in volts.

- * 33. (II) Use the result of Example 28–6 to estimate the X-ray wavelength emitted when a Co $(Z = 27)$ atom jumps from $n = 2$ to $n = 1$.
- * 34. (II) Estimate the wavelength for an $n = 2$ to $n = 1$ transition in iron $(Z = 26)$.
- *35. (II) Use the Bohr theory to estimate the wavelength for an $n = 3$ to $n = 1$ transition in molybdenum (Z = 42). The measured value is 0.063 nm. Why do we not expect perfect agreement?

General Problems

- 41. Use the uncertainty principle to estimate the position uncertainty for the electron in the ground state of the hydrogen atom. [*Hint*: determine the momentum using the Bohr model of Section 27-12 and assume the momentum can be anywhere between this value and zero.] How does this result compare to the Bohr radius?
- 42. An electron in the $n = 2$ state of hydrogen remains there on average about 10^{-8} s before jumping to the $n = 1$ state. (a) Estimate the uncertainty in the energy of the $n = 2$ state. (b) What fraction of the transition energy is this? (c) What is the wavelength, and width (in nm), of this line in the spectrum of hydrogen?
- 43. What are the largest and smallest possible values for the angular momentum L of an electron in the $n = 5$ shell?
- **44.** Estimate (a) the quantum number *l* for the orbital angular momentum of the Earth about the Sun, and (b) the number of possible orientations for the plane of Earth's orbit.
- 45. A 12-g bullet leaves a rifle at a speed of 180 m/s . (a) What is the wavelength of this bullet? (b) If the position of the bullet is known to an accuracy of 0.60 cm (radius of the barrel), what is the minimum uncertainty in its momentum?
- 46. Using the Bohr formula for the radius of an electron orbit, estimate the average distance from the nucleus for an electron in the innermost $(n = 1)$ orbit of a uranium atom $(Z = 92)$. Approximately how much energy would be required to remove this innermost electron?

*36. (II) A mixture of iron and an unknown material is bombarded with electrons. The wavelength of the K_n lines are 194 pm for iron and 229 pm for the unknown. What is the unknown material?

* 28-11 Lasers

- *37. (II) A laser used to weld detached retinas puts out 28-ms-long pulses of 640-nm light which average 0.68-W output during a pulse. How much energy can be deposited per pulse and how many photons does each pulse contain? [*Hint*: see Example 27-5.]
- *38. (II) A low-power laser used in a physics lab might have a power of 0.50 mW and a beam diameter of 3.0 mm. Calculate (a) the average light intensity of the laser beam, and (b) compare it to the intensity of a lightbulb producing 40-W light viewed from 2.0 m.
- *39. (II) Estimate the angular spread of a laser beam due to diffraction if the beam emerges through a 3.0-mm-diameter mirror. Assume that $\lambda = 694$ nm. What would be the diameter of this beam if it struck (a) a satellite 300 km above the Earth, or (b) the Moon? [*Hint*: see Section 25-7.]
- * 40. (II) What is the wavelength of the He-Ne laser?

- 47. An X-ray tube operates at 95 kV with a current of 25 mA and nearly all the electron energy goes into heat. If the specific heat of the 0.085-kg plate is 0.11 kcal/kg· C° . what will be the temperature rise per minute if no cooling water is used?
- 48. The ionization (binding) energy of the outermost electron in boron is 8.26 eV . (a) Use the Bohr model to estimate the "effective charge," Zeff, seen by this electron. (b) Estimate the average orbital radius.
- 49. Use the Bohr theory (especially Eq. $27-16$) to show that the Moseley plot (Fig. $28-12$) can be written

$$
\sqrt{\frac{1}{\lambda}} = a(Z - b),
$$

where $b \approx 1$, and evaluate a.

- 50. (a) Show that the number of different states for a given value of *l* is equal to $2(2l + 1)$. (*b*) What is this number for $l = 0, 1, 2, 3, 4, 5,$ and 6?
- 51. Show that the number of different electron states possible for a given value of *n* is $2n^2$. (See Problem 50.)
- 52. A beam of electrons with kinetic energy 45 keV is shot through two narrow slits in a barrier. The slits are a distance 2.0×10^{-6} m apart. If a screen is placed 35.0 cm behind the barrier, calculate the spacing between the "bright" fringes of the interference pattern produced on the screen.
- 53. The angular momentum in the hydrogen atom is given both by the Bohr model and by quantum mechanics. Compare the results for $n = 2$.
- 54. An 1100-kg car is traveling with a speed of (22 ± 0.22) m/s. With what maximum accuracy can its position be determined?
- 55. An atomic spectrum contains a line with a wavelength centered at 488 nm. Careful measurements show the line is really spread out between 487 and 489 nm. Estimate the lifetime of the excited state that produced this line.
- 56. Protons are accelerated from rest across 550 V. They are then directed at two slits 0.70 mm apart. How far apart will the interference peaks be on a screen 28 m away?
- 57. An electron and a proton, each initially at rest, are accelerated across the same voltage. Assuming that the uncertainty in their position is given by their de Broglie wavelength, find the ratio of the uncertainty in their momentum.
- **58.** If the principal quantum number n were limited to the range from 1 to 6, how many elements would we find in nature?
- 59. If your de Broglie wavelength were 0.50 m, how fast would you be moving if your mass is 75.0 kg? Would you notice diffraction effects as you walk through a doorway? Approximately how long would it take you to walk through the doorway?
- 60. Suppose that the spectrum of an unknown element shows a series of lines with one out of every four matching a line from the Lyman series of hydrogen. Assuming that the unknown element is an ion with Z protons and one electron, determine Z and the element in question.
- * 61. Photons of wavelength 0.154 nm are emitted from the surface of a certain metal when it is bombarded with high energy radiation. If this photon wavelength corresponds to the K_{α} line, what is the element?
- * 62. Show that the diffractive spread of a laser beam, $\approx \lambda/D$ as described in Section 28-11, is precisely what you might expect from the uncertainty principle. [Hint: since the beam's width is constrained by the dimension of the aperture D , the component of the light's momentum perpendicular to the laser axis is uncertain.]

Answers to Exercises

A: 2.1×10^{-24} kg·m/s, 2.3×10^6 m/s. **B:** 2, 1, 0, -1, -2.

C: -0.38 eV, $\sqrt{20}$ \hbar . **D:** $1s^22s^22p^63s^23p^63d^{10}4s^24p^1$. A Pentium 4 chip is one of the leading processors used in computers today. The 2004 model contains 125 million transistors, plus diodes and other semiconductor electronic elements, all on a chip only about 1 cm on a side. Before discussing semiconductors and their applications, we study how quantum theory describes bonding of atoms to form molecules, and how it explains molecular behavior. We then examine how atoms and molecules form solids, with emphasis on metals and semiconductors, and their use in electronics.

CHAPTER

Molecules and Solids

ince its development in the 1920s, quantum mechanics has had a profound influence on our lives, both intellectually and technologically. Even the way we view the world has changed, as we saw in Chapter 28. Now we discuss how quantum mechanics has given us an understanding of the structure of molecules and matter in bulk, as well as a number of important applications including semiconductor devices and applications to biology.

29-1 Bonding in Molecules

One of the great successes of quantum mechanics was to give scientists, at last, an understanding of the nature of chemical bonds. Since it is based in physics, and because this understanding is so important in many fields, we discuss it here.

By a molecule, we mean a group of two or more atoms that are strongly held together so as to function as a single unit. When atoms make such an attachment, we say that a chemical **bond** has been formed. There are two main types of strong chemical bond: covalent and ionic. Many bonds are actually intermediate between these two types.

Covalent Bonds

To understand how **covalent bonds** are formed, we take the simplest case, the bond that holds two hydrogen atoms together to form the hydrogen molecule, H_2 . The mechanism is basically the same for other covalent bonds. As two H atoms approach each other, the electron clouds begin to overlap, and the electrons from each atom can "orbit" both nuclei. (This is sometimes called "sharing" electrons.) If both electrons are in the ground state $(n = 1)$ of their respective atoms, there are two possibilities: their spins (Chapter 28) can be parallel (both up or both down), in which case the total spin is $S = \frac{1}{2} + \frac{1}{2} = 1$; or their spins can be opposite $(m_s = +\frac{1}{2}$ for one, $m_s = -\frac{1}{2}$ for the other), so that the total spin $S = 0$. We shall now see that a bond is formed only for the $S = 0$ state, when the spins are opposite.

First we consider the $S = 1$ state, for which the spins are the same. The two electrons cannot both be in the lowest energy state and be attached to the same atom, for then they would have identical quantum numbers in violation of the exclusion principle. The exclusion principle tells us that since no two electrons can occupy the same quantum state, if two electrons have the same quantum numbers, they must be different in some other way—namely, by being in different places in space (for example, attached to different atoms). When the two atoms approach each other, the electrons will stay away from each other as shown by the probability distribution of Fig. $29-1$. The positively charged nuclei then repel each other, and no bond is formed.

For the $S = 0$ state, on the other hand, the spins are opposite and the two electrons are consequently in different quantum states (m_s is different, $+\frac{1}{2}$ for one, $-\frac{1}{2}$ for the other). Hence they can come close together. In this case, the probability distribution looks like Fig. 29-2: the electrons can spend much of their time between the two nuclei. The two positively charged nuclei are attracted to the negatively charged electron cloud between them, and this is the attraction that holds the two atoms together to form a molecule. This is a covalent bond.

The probability distributions of Figs. $29-1$ and $29-2$ can perhaps be better understood on the basis of waves. What the exclusion principle requires is that when the spins are the same, there is destructive interference of the electron wave functions in the region between the two atoms. But when the spins are opposite, constructive interference occurs in the region between the two atoms, resulting in a large amount of negative charge there. Thus a covalent bond can be said to be the result of constructive interference of the electron wave functions in the space between the two atoms, and of the electrostatic attraction of the two positive nuclei for the negative charge concentration between them.

Why a bond is formed can also be understood from the energy point of view. When the two H atoms approach close to one another, if the spins of their electrons are opposite, the electrons can occupy the same space, as discussed above. This means that each electron can now move about in the space of two atoms instead of in the volume of only one. Because each electron now occupies more space, it is less well localized. Because each electron has a larger "orbit," its wavelength λ can be longer, so its momentum $p = h/\lambda$ (Eq. 27–8) can be less. With less momentum, each electron has less energy when the two atoms combine than when they are separate. That is, the molecule has less energy than the two separate atoms, and so is more stable. An energy input is required to break the H_2 molecule into two separate H atoms, so the H_2 molecule is a stable entity. This is what we mean by a *bond*. The energy required to break a bond is called the **bond energy**, the **binding energy**, or the **dissociation energy**. For the hydrogen molecule, H_2 , the bond energy is 4.5 eV.

Covalent **h**ond

FIGURE 29-1 Electron probability distribution (electron cloud) for two H atoms when their spins are the same $(S = \frac{1}{2} + \frac{1}{2} = 1)$.

FIGURE 29-2 Electron probability distribution (cloud) around two H atoms when their spins are opposite $(S = 0)$. In this case, a bond is formed because the positive nuclei are attracted to the concentration of negative charge between them. This is a hydrogen molecule, H_2 .

Energy explanation of bond

Bond energy

Ionic Bonds

FIGURE 29-3 Probability distribution for the last electron of Na in NaCl.

FIGURE 29-4 In a neutral sodium atom, the 10 inner electrons shield the nucleus, so the single outer electron is attracted by a net charge of $+1e$.

An **ionic bond** is, in a sense, a special case of the covalent bond. Instead of the electrons being shared equally, they are shared unequally. For example, in sodium chloride (NaCl), the outer electron of the sodium spends nearly all its time around the chlorine (Fig. 29–3). The chlorine atom acquires a net negative charge as a result of the extra electron, whereas the sodium atom is left with a net positive charge. The electrostatic attraction between these two charged atoms holds them together. The resulting bond is called an *ionic bond* because it is created by the attraction between the two ions ($Na⁺$ and $Cl⁻$). But to understand the ionic bond, we must understand why the extra electron from the sodium spends so much of its time around the chlorine. After all, the chlorine is neutral; why should it attract another electron?

The answer lies in the probability distributions of the two neutral atoms. Sodium contains 11 electrons, 10 of which are in spherically symmetric closed shells (Fig. 29-4). The last electron spends most of its time beyond these closed shells. Because the closed shells have a total charge of $-10e$ and the nucleus has charge $+11e$, the outermost electron in sodium "feels" a net attraction due to $+1e$. It is not held very strongly. On the other hand, 12 of chlorine's 17 electrons form closed shells, or subshells (corresponding to $1s²2s²2p⁶3s²$). These 12 form a spherically symmetric shield around the nucleus. The other five electrons are in $3p$ states whose probability distributions are not spherically symmetric and have a form similar to those for the $2p$ states in hydrogen shown in Fig. 28-9b and c. Four of these $3p$ electrons can have "doughnut-shaped" distributions symmetric about the z axis, as shown in Fig. 29-5. The fifth can have a "barbell-shaped" distribution (as for $m_l = 0$ in Fig. 28–9b), which in Fig. 29–5 is shown only in dashed outline because it is half empty. That is, the exclusion principle allows one more electron to be in this state (it will have spin opposite to that of the electron already there). If an extra electron-say from a Na atom-happens to be in the vicinity, it can be in this state, say at point x in Fig. 29–5. It could experience an attraction due to as much as $+5e$ because the $+17e$ of the nucleus is partly shielded at this point by the 12 inner electrons. Thus, the outer electron of a sodium atom will be more strongly attracted by the $+5e$ of the chlorine atom than by the $+1e$ of its own atom. This, combined with the strong attraction between the two ions when the extra electron stays with the Cl⁻, produces the charge distribution of Fig. 29-3, and hence the ionic bond.

Partial Ionic Character of Covalent Bonds

A pure covalent bond in which the electrons are shared equally occurs mainly in symmetrical molecules such as H_2 , O_2 , and Cl_2 . When the atoms involved are different from each other, it is usual to find that the shared electrons are more likely to be in the vicinity of one atom than the other. The extreme case is an ionic bond; in intermediate cases the covalent bond is said to have a partial *ionic character*. The molecules themselves are **polar**—that is, one part (or parts) of the molecule has a net positive charge and other parts a net negative charge. An example is the water molecule, $H₂O$ (Fig. 29–6). The shared electrons are more likely to be found around the oxygen atom than around the two hydrogens.

The reason is similar to that discussed above in connection with ionic bonds. Oxygen has eight electrons $(1s^22s^22p^4)$, of which four form a spherically symmetric core and the other four could have, for example, a doughnut-shaped distribution. The barbell-shaped distribution on the z axis (like that shown dashed in Fig. 29–5) could be empty, so electrons from hydrogen atoms can be attracted by a net charge of $+4e$. They are also attracted by the H nuclei, so they partly orbit the H atoms as well as the O atom. The net effect is that there is a net positive charge on each H atom (less than $+1e$), because the electrons spend only part of their time there. And, there is a net negative charge on the O atom.

29-2 Potential-Energy Diagrams for Molecules

It is useful to analyze the interaction between two objects-say, between two atoms or molecules—with the use of a potential-energy diagram, a plot of the potential energy versus the separation distance.

For the simple case of two point charges, q_1 and q_2 , the PE is given by (we combine Eqs. $17-2$ and $17-5$)

$$
PE = \frac{1}{4\pi\epsilon_0} \frac{q_1 q_2}{r},
$$

where r is the distance between the charges, and the constant $(1/4\pi\epsilon_0)$ is equal to 9.0×10^9 N·m²/C². If the two charges have the same sign, the PE is positive for all values of r , and a graph of PE versus r in this case is shown in Fig. 29–7a. The force is repulsive (the charges have the *same* sign) and the curve rises as r decreases; this makes sense since work is done to bring the charges together, thereby increasing their potential energy. If, on the other hand, the two charges are of the *opposite* sign, the PE is negative because the product q_1q_2 is negative. The force is attractive in this case, and the graph of PE versus r looks like Fig. 29–7b. The PE becomes more *negative* as *r* decreases.

Polar molecules

Now let us look at the potential-energy diagram for the formation of a covalent bond, such as for the hydrogen molecule, $H₂$. The potential energy of one H atom in the presence of the other is plotted in Fig. $29-8$. Starting at large r, the PE decreases as the atoms approach, because the electrons concentrate between the two nuclei (Fig. 29–2), so attraction occurs. However, at very short distances, the electrons would be "squeezed out"—there is no room for them between the two nuclei. Without the electrons between them, each nucleus would feel a repulsive force due to the other, so the curve rises as r decreases further. There is an optimum separation of the atoms, r_0 in Fig. 29–8, at which the energy is lowest. This is the point of greatest stability for the hydrogen molecule, and r_0 is the average separation of atoms in the H_2 molecule. The depth of this "well" is the *binding energy*,^{\dagger} as shown. This is how much energy must be put into the system to separate the two atoms to infinity, where the $PE = 0$. For the H₂ molecule, the binding energy is about 4.5 eV and $r_0 = 0.074$ nm.

Binding energy

FIGURE 29-8 Potential-energy diagram for H_2 molecule; r is the separation of the two H atoms. The binding energy (the energy difference between $PE = 0$ and the lowest energy state near the bottom of the well) is 4.5 eV, and $r_0 = 0.074$ nm.

For many bonds, the potential-energy curve has the shape shown in Fig. 29–9. There is still an optimum distance r_0 at which the molecule is stable. But when the atoms approach from a large distance, the force is initially repulsive rather than attractive. The atoms thus do not interact spontaneously. Instead, some additional energy must be injected into the system to get it over the "hump" (or barrier) in the potential-energy diagram. This required energy is called the activation energy.

Activation energy

The curve of Fig. 29–9 is much more common than that of Fig. 29–8. The activation energy often reflects a need to break other bonds, before the one under discussion can be made. For example, to make water from O_2 and H_2 , the H_2 and O_2 molecules must first be broken into H and O atoms by an input of energy; this is what the activation energy represents. Then the H and O atoms

[†]The binding energy corresponds not quite to the bottom of the PE curve, but to the lowest energy state, slightly above it, as shown in Fig. 29-8.

can combine to form $H₂O$ with the release of a great deal more energy than was put in initially. The initial activation energy can be provided by applying an electric spark to a mixture of H_2 and O_2 , breaking a few of these molecules into H and O atoms. The resulting explosive release of energy when these atoms combine to form H_2O quickly provides the activation energy needed for further reactions, so additional H_2 and O_2 molecules are broken up and recombined to form H₂O.

The potential-energy diagrams for ionic bonds can have similar shapes. In NaCl, for example, the Na⁺ and Cl⁻ ions attract each other at distances a bit larger than some r_0 , but at shorter distances the overlapping of inner electron shells gives rise to repulsion. The two atoms thus are most stable at some intermediate separation, r_0 , and there often is an activation energy.

Sometimes the potential energy of a bond looks like that of Fig. 29–10. In this case, the energy of the bonded molecule, at a separation r_0 , is greater than when there is no bond $(r = \infty)$. That is, an energy *input* is required to make the bond (hence the binding energy is negative), and there is energy release when the bond is broken. Such a bond is stable only because there is the barrier of the activation energy. This type of bond is important in living cells, for it is in such bonds that energy can be stored efficiently in certain molecules, particularly ATP (adenosine triphosphate). The bond that connects the last phosphate group (designated (P) in Fig. 29–10) to the rest of the molecule (ADP, meaning adenosine diphosphate, since it contains only two phosphates) has PE of the shape shown in Fig. 29-10. Energy is stored in this bond. When the bond is broken $(ATP \rightarrow ADP + (P))$, energy is released and this energy can be used to make other chemical reactions "go."

FIGURE 29-10 Potential-energy diagram for the formation of ATP from ADP and phosphate ((P).

In living cells, many chemical reactions have activation energies that are often on the order of several eV. Such energy barriers are not easy to overcome in the cell. This is where enzymes come in. They act as *catalysts*, which means they act to lower the activation energy so that reactions can occur that otherwise would not. Enzymes act by distorting the bonding electron clouds, so that the initial bonds are easily broken.

Enzymes act to lower activation energy

29-3 Weak (van der Waals) Bonds

Once a bond between two atoms or ions is made, energy must normally be supplied to break the bond and separate the atoms. As mentioned in Section $29-1$, this energy is called the *bond energy* or *binding energy*. The binding energy for covalent and ionic bonds is typically 2 to 5 eV. These bonds, which hold atoms together to *form* molecules, are often called **strong bonds** to distinguish them from so-called "weak bonds." The term weak bond, as we use it here, refers to an attachment *between* molecules due to simple electrostatic attraction—such as *between* polar molecules (and not *within* a polar molecule, which is a strong bond). The strength of the attachment is much less than for the strong bonds. Binding energies are typically in the range 0.04 to 0.3 eV —hence their name "weak bonds."

FIGURE 29-11 The C^+ — O^- and H^+ —N⁻ dipoles attract each other. (These dipoles may be part of, for example, cytosine and guanine molecules. See Fig. 29-12.) The $+$ and $-$ charges typically have magnitudes of a fraction of e .

PHYSICS APPLIED DNA

Weak bonds are generally the result of attraction between dipoles. (Two equal point charges Q , of opposite sign, separated by a distance l , are called an electric dipole, as we saw in Chapter 17.) For example, Fig. 29-11 shows two molecules, which have permanent dipole moments, attracting one another. Besides such dipole-dipole bonds, there can also be dipole-induced dipole bonds, in which a polar molecule with a permanent dipole moment can induce a dipole moment in an otherwise electrically balanced (nonpolar) molecule, just as a single charge can induce a separation of charge in a nearby object (see Fig. 16–7). There can even be an attraction between two nonpolar molecules, because their electrons are moving about: at any instant there may be a transient separation of charge, creating a weak attraction. All these weak bonds are referred to as van der Waals bonds, and the forces involved van der Waals forces. The potential energy has the general shape shown in Fig. 29-8, with the attractive van der Waals PE varying as $1/r^6$.

When one of the atoms in a dipole-dipole bond is hydrogen, as in Fig. $29-11$, it is called a **hydrogen bond**. A hydrogen bond is generally the strongest of the weak bonds, because the hydrogen atom is the smallest atom and can be approached more closely. Hydrogen bonds also have a partial "covalent" character: that is, electrons between the two dipoles may be shared to a small extent, making a stronger, more lasting bond.

Weak bonds are important in liquids and solids when strong bonds are absent (see Section $29-5$). They are also very important for understanding the activities of cells, such as the double helix shape of DNA (Fig. $29-12$), and DNA replication (see Section 16-11). The average kinetic energy of molecules in a living cell at normal temperatures $(T \approx 300 \text{ K})$ is around $\frac{3}{2}kT \approx 0.04 \text{ eV}$, about the magnitude of weak bonds. This means that a weak bond can readily be broken just by a molecular collision. Hence weak bonds are not very permanent—they are,

FIGURE 29-12 (a) Section of a DNA double helix. The red dots represent hydrogen bonds between the two strands. (b) "Close-up" view: cytosine (C) and guanine (G) molecules on separate strands of a DNA double helix are held together by the hydrogen bonds (red dots) involving an $H⁺$ on one molecule attracted to an N⁻ or C⁺-O⁻ of a molecule on the adjacent chain. See also Section 16-11 and Figs. 16-44 and 16-45.

instead, brief attachments. This helps them play particular roles in the cell. On the other hand, strong bonds—those that hold molecules together—are almost never broken simply by molecular collision. Thus they are relatively permanent. They can be broken by chemical action (the making of even stronger bonds). and this usually happens in the cell with the aid of an enzyme, which is a protein molecule.

EXAMPLE 29-1 Nucleotide energy. Calculate the potential energy between the $C=O$ dipole of thymine and the $H-N$ dipole of adenine, assuming that the two dipoles are lined up as shown in Fig. 29-11. Dipole moment measurements (see Table 17-2) give

and

$$
q_{\rm H} = -q_{\rm N} = 0.19e = 3.0 \times 10^{-20} \text{ C},
$$

 $q_{\rm C} = -q_{\rm O} = 0.41e = 6.6 \times 10^{-20} \text{ C}.$

APPROACH We want to find the potential energy of the two charges in one dipole due to the two charges in the other, since this will be equal to the work needed to pull them infinitely far apart. The potential energy PE of a charge q_1 in the presence of a charge q_2 is

$$
PE = k \frac{q_1 q_2}{r_{12}}
$$

where $k = 9.0 \times 10^9 \,\text{N} \cdot \text{m}^2/\text{C}^2$ (see Eqs. 17–2 and 17–5).

SOLUTION The potential energy (we use the symbol U) will consist of four terms:

$$
U = U_{\rm CH} + U_{\rm CN} + U_{\rm OH} + U_{\rm ON},
$$

where U_{CH} means the potential energy of C in the presence of H, and similarly for the other terms. We do not have terms corresponding to C and O , or N and H , because the two dipoles are assumed to be stable entities. Then

$$
U = k \frac{q_{\rm C} q_{\rm H}}{r_{\rm CH}} + k \frac{q_{\rm C} q_{\rm N}}{r_{\rm CN}} + k \frac{q_{\rm O} q_{\rm H}}{r_{\rm OH}} + k \frac{q_{\rm O} q_{\rm N}}{r_{\rm ON}}.
$$

Using the distances shown in Fig. $29-11$, we get:

$$
U = (9.0 \times 10^{9} \,\text{N} \cdot \text{m}^{2}/\text{C}^{2}) \bigg(\frac{(6.6)(3.0)}{0.31} + \frac{(6.6)(-3.0)}{0.41} + \frac{(-6.6)(3.0)}{0.19} + \frac{(-6.6)(-3.0)}{0.29} \bigg) \frac{(10^{-20} \,\text{C})^{2}}{(10^{-9} \,\text{m})}
$$

= -1.83 × 10⁻²⁰ J
= -
$$
\frac{(1.83 \times 10^{-20} \,\text{J})}{(1.60 \times 10^{-19} \,\text{J/eV})} = -0.11 \,\text{eV}.
$$

The PE is negative, meaning 0.11 eV of work (or energy input) is required to separate the molecules. That is, the binding energy of this "weak" or hydrogen bond is 0.11 eV. This is only an estimate, of course, since other charges in the vicinity would have an influence too.

Protein Synthesis

Weak bonds, especially hydrogen bonds, are crucial to the process of protein synthesis. Proteins serve as structural parts of the cell and as enzymes to catalyze chemical reactions needed for the growth and survival of the organism. A protein molecule consists of one or more chains of small molecules known as amino acids.

FIGURE 29-13 Protein synthesis.

APPLIED Protein synthesis

 λ) PHYSICS

The standard model for how amino acids are connected together in the correct order to form a protein molecule is shown schematically in Fig. 29-13. It begins at the DNA double helix, for each gene on a chromosome contains the information for producing one protein. The ordering of the four bases, A, C, G, and T, provides the "code," the "genetic code," for the order of amino acids in the protein. First, the DNA double helix unwinds and a new molecule called *messenger*-RNA (m-RNA) is synthesized using one strand of the DNA as a "template." m-RNA is a chain molecule containing four different bases, like those of DNA except that thymine (T) is replaced by the similar uracil molecule (U). In Fig. $29-13$, a C has just been added to the growing m-RNA chain in much the same way that DNA replicates (Fig. 16–45); and an A, attracted and held close to the T on the DNA chain by the electrostatic force, will soon be attached to the C by an enzyme. The order of the bases, and thus the genetic information, is preserved in the m-RNA. The m-RNA is buffeted about in the cell (remember kinetic theory) until it gets close to a tiny organelle known as a ribosome, to which it can become attached by electrostatic attraction, Fig. 29-13. Also held by the electrostatic force to the ribosome are one or two transfer-RNA (t-RNA) molecules. These t-RNA molecules "translate" the genetic code of nucleotide bases into amino acids in the following way. There is a different t-RNA molecule for each combination of three bases. At one end of the t-RNA molecule is the "anticodon," a set of three nucleotide bases. If all three bases of the anticodon match (in the sense of G to C and A to U) the three bases of the "codon" on the m-RNA at its attachment to the ribosome, the anticodon is attracted electrostatically to the m-RNA codon and is held there briefly. On the other end of a t-RNA molecule is the appropriate amino acid. The ribosome has two particular attachment sites which hold two t-RNA molecules while enzymes link their two amino acids together to lengthen the amino acid chain (yellow in Fig. 29–13). As each amino acid is connected by an enzyme (4 are already connected in Fig. 29–13, a fifth is about to be connected), the old t-RNA molecule is removed—perhaps by a random collision with some molecule in the cellular fluid. A new one soon becomes attracted as the ribosome moves along the m-RNA.

This process of protein synthesis is often presented as if it occurred in clockwork fashion—as if each molecule knew its role and went to its assigned place. But this is not the case. The forces of attraction between the electric charges of the molecules are rather weak and become significant only when the molecules can come close together and several weak bonds can be made. Indeed, if the shapes are not just right, there is almost no electrostatic attraction, which is why there are few mistakes. The fact that weak bonds are weak is very important. If they were strong, collisions with other molecules would not allow a t-RNA molecule to be released from the ribosome, or the m-RNA to be released from the DNA. If they were not temporary encounters, metabolism would grind to a halt.

As each amino acid is added to the next, the protein molecule grows in length until it is complete. Even as it is being made, this chain is being buffeted about in the cellular sea—we might think of a wiggling worm. But a protein molecule has electrically charged polar groups along its length. And as it takes on various shapes, the electric forces of attraction between different parts of the molecule will eventually lead to a particular configuration that is quite stable. Each type of protein has its own special shape, depending on the location of charged atoms. In the last analysis, the final shape depends on the order of the amino acids.

-4 Molecular Spectra 29

When atoms combine to form molecules, the probability distributions of the outer electrons overlap and this interaction alters the energy levels. Nonetheless, molecules can undergo transitions between electron energy levels just as atoms do. For example, the H_2 molecule can absorb a photon of just the right frequency to excite one of its ground-state electrons to an excited state. The excited electron can then return to the ground state, emitting a photon. The energy of photons emitted by molecules is of the same order of magnitude as for atoms, typically 1 to 10 eV.

Additional energy levels become possible for molecules (but not for atoms) because the molecule as a whole can rotate, and the atoms of the molecule can vibrate relative to each other. The energy levels for both rotational and vibrational levels are quantized, and are generally spaced much more closely $(10^{-3}$ to 10^{-1} eV) than the electronic levels. Each atomic energy level thus becomes a set of closely spaced levels corresponding to the vibrational and rotational motions, Fig. 29-14. Transitions from one level to another appear as many very closely spaced lines. In fact, the lines are not always distinguishable, and these spectra are called band spectra. Each type of molecule has its own characteristic spectrum, which can be used for identification and for determination of structure. We now look in more detail at rotational and vibrational states in molecules.

> FIGURE 29-14 (a) The individual energy levels of an isolated atom become (b) bands of closely spaced levels in molecules, as well as in solids and liquids.

Protein shape

Selection rule (rotational levels)

FIGURE 29-16 Rotational energy levels and allowed transitions (emission and absorption) for a diatomic molecule. Upward-pointing arrows represent absorption of a photon, and downward arrows represent emission of a photon.

* Rotational Energy Levels in Molecules

We consider only diatomic molecules, although the analysis can be extended to polyatomic molecules. When a diatomic molecule rotates about its center of mass as shown in Fig. $29-15$, its kinetic energy of rotation (see Section 8-7) is

$$
E_{\rm rot} = \frac{1}{2}I\omega^2 = \frac{(I\omega)^2}{2I}
$$

where $I\omega$ is the angular momentum (Section 8–8). Quantum mechanics predicts quantization of angular momentum just as in atoms (see Eq. 28–3):

$$
I\omega = \sqrt{L(L+1)}\hbar
$$
, $L = 0, 1, 2, \dots$

where L is an integer called the **rotational angular momentum quantum** number. Thus the rotational energy is quantized:

$$
E_{\rm rot} = \frac{(I\omega)^2}{2I} = L(L+1)\frac{\hbar^2}{2I}, \qquad L = 0, 1, 2, \cdots.
$$
 (29-1)

Transitions between rotational energy levels are subject to the *selection rule* (as in Section $28-6$):

$$
\Delta L = \pm 1
$$

The energy of a photon emitted or absorbed for a transition between rotational states with angular momentum quantum number L and $L - 1$ will be

We see that the transition energy increases directly with L . Figure 29–16 shows some of the allowed rotational energy levels and transitions. Measured absorption lines fall in the microwave or far-infrared regions of the spectrum, and their frequencies are generally 2, 3, 4, \cdots times higher than the lowest one, as predicted by Eq. 29-2.

EXAMPLE 29-2 Rotational transition. A rotational transition $L = 1$ to $L = 0$ for the molecule CO has a measured absorption wavelength λ_1 = 2.60 mm (microwave region). Use this to calculate (*a*) the moment of inertia of the CO molecule, and (b) the CO bond length, r .

APPROACH The absorption wavelength is used to find the energy of the absorbed photon, and we can then calculate the moment of inertia, I, from Eq. 29–2. The moment of inertia is related to the CO separation (bond length r). **SOLUTION** (a) The photon energy, $E = hf = hc/\lambda$, equals the rotational energy level difference, ΔE_{rot} . From Eq. 29–2, we can write

$$
\frac{\hbar^2}{I}L = \Delta E_{\text{rot}} = hf = \frac{hc}{\lambda_1}
$$

With $L = 1$ (the upper state) in this case, we solve for I:

$$
I = \frac{\hbar^2 L}{hc} \lambda_1 = \frac{h\lambda_1}{4\pi^2 c} = \frac{(6.63 \times 10^{-34} \,\text{J} \cdot \text{s})(2.60 \times 10^{-3} \,\text{m})}{4\pi^2 (3.00 \times 10^8 \,\text{m/s})}
$$

= 1.46 × 10⁻⁴⁶ kg·m².

(b) The molecule rotates about its center of mass (CM) as shown in Fig. $29-15$. Let m_1 be the mass of the C atom, $m_1 = 12u$, and let m_2 be the mass of the O, $m_2 = 16$ u. The distance of the CM from the C atom, which is r_1 in Fig. $29-15$, is given by the CM formula, Eq. 7-9:

$$
r_1 = \frac{0 + m_2 r}{m_1 + m_2} = \frac{16}{12 + 16} r = 0.57r.
$$

The O atom is a distance $r_2 = r - r_1 = 0.43r$ from the CM. The moment of

inertia of the CO molecule about its CM is then (see Example 8–10)

$$
I = m_1 r_1^2 + m_2 r_2^2
$$

= [(12 u)(0.57r)² + (16 u)(0.43r)²][1.66 × 10⁻²⁷ kg/u]
= (1.14 × 10⁻²⁶ kg)r².

We solve for r and use the result of part (a) for I :

$$
r = \sqrt{\frac{1.46 \times 10^{-46} \,\text{kg} \cdot \text{m}^2}{1.14 \times 10^{-26} \,\text{kg}}} = 1.13 \times 10^{-10} \,\text{m} = 0.113 \,\text{nm}.
$$

EXERCISE A What are the wavelengths of the next three rotational transitions for CO?

* Vibrational Energy Levels in Molecules

The potential energy of the two atoms in a typical diatomic molecule has the shape shown in Fig. 29–8 or 29–9, and Fig. 29–17 again shows the PE for the H_2 molecule (solid curve). This PE curve, at least in the vicinity of the equilibrium separation r_0 , closely resembles the potential energy of a harmonic oscillator, $PE = \frac{1}{2}kx^2$, which is shown superimposed in dashed lines. Thus, for small displacements from r_0 , each atom experiences a restoring force approximately proportional to the displacement, and the molecule vibrates as a simple harmonic oscillator (SHO)—see Chapter 11. According to quantum mechanics, the possible energy levels are quantized according to

$$
E_{\text{vib}} = (\nu + \frac{1}{2})hf, \qquad \nu = 0, 1, 2, \cdots,
$$
 (29-3)

where f is the classical frequency (see Chapter $11-f$ depends on the mass of the atoms and on the bond strength or "stiffness") and ν is an integer called the **vibrational quantum number.** The lowest energy state $(\nu = 0)$ is not zero (as for rotation), but has $E = \frac{1}{2}hf$. This is called the **zero-point energy**. Higher states have energy $\frac{3}{2}hf$, $\frac{5}{2}hf$, and so on, as shown in Fig. 29–18. Transitions are subject to the selection rule:

$$
\Delta \nu = \pm 1,
$$

so allowed transitions occur only between adjacent states, and all give off photons of energy

$$
\Delta E_{\rm vib} = hf.
$$

This is very close to experimental values for small ν , but for higher energies, the PE curve (Fig. 29–17) begins to deviate from a perfect SHO curve, and this then affects the wavelengths and frequencies of the transitions. Typical transition energies are on the order of 10^{-1} eV, about 10 times larger than for rotational transitions, with wavelengths in the infrared region of the spectrum ($\approx 10^{-5}$ m).

EXAMPLE 29-3 Vibrational energy levels in hydrogen. Hydrogen molecule vibrations emit infrared radiation of wavelength around 2300 nm. (a) What is the separation in energy between adjacent vibrational levels? (b) What is the lowest vibrational energy state?

APPROACH The energy separation between adjacent vibrational levels is (Eq. 29–4) $\Delta E_{\text{vib}} = hf = hc/\lambda$. The lowest energy (Eq. 29–3) has $\nu = 0$. **SOLUTION**

(a)
$$
\Delta E_{\text{vib}} = hf = \frac{hc}{\lambda} = \frac{(6.63 \times 10^{-34} \text{ J} \cdot \text{s})(3.00 \times 10^8 \text{ m/s})}{(2300 \times 10^{-9} \text{ m})(1.60 \times 10^{-19} \text{ J/eV})} = 0.54 \text{ eV}
$$

where the denominator includes the conversion factor from joules to eV. (b) The lowest vibrational energy has $\nu = 0$ in Eq. 29–3:

$$
E_{\text{vib}} = (\nu + \frac{1}{2})hf = \frac{1}{2}hf = 0.27 \text{ eV}.
$$

EXERCISE B What is the energy of the first vibrational state above the ground state in the hydrogen molecule?

FIGURE 29-17 Potential energy for the H₂ molecule and for a simple harmonic oscillator (PE = $\frac{1}{2}kx^2$, with $|x| = |r - r_0|$).

Selection rule (vibrational energy)

 $(29-4)$

FIGURE 29-18 Allowed vibrational energies for a diatomic molecule, where f is the fundamental frequency of vibration (see Chapter 11). The energy levels are equally spaced. Transitions are allowed only between adjacent levels ($\Delta \nu = \pm 1$).

FIGURE 29-19 Arrangement of atoms in (a) a simple cubic crystal, (b) face-centered cubic crystal (note the atom at the center of each face), and (c) body-centered cubic crystal. Each diagram shows the relationship of the bonds. Each of these "cells" is repeated in three dimensions to the edges of the macroscopic crystal.

FIGURE 29-20 Diagram of an NaCl crystal, showing the "packing" of atoms.

29-5 Bonding in Solids

Quantum mechanics has been a great tool for understanding the structure of solids. This active field of research today is called solid-state physics, or condensed-matter physics so as to include liquids as well. The rest of this Chapter is devoted to this subject, and we begin with a brief look at the structure of solids and the bonds that hold them together.

Although some solid materials are *amorphous* in structure (such as glass), in that the atoms and molecules show no long-range order, we are interested here in the large class of *crystalline* substances whose atoms, ions, or molecules are generally accepted to form an orderly array in a geometric arrangement known as a lattice. Figure 29–19 shows three of the possible arrangements of atoms in a crystal: simple cubic, face-centered cubic, and body-centered cubic. The NaCl crystal lattice is face-centered cubic, with one Na⁺ ion or one Cl⁻ ion at each lattice point (see Fig. 29-20).

The molecules of a solid are held together in a number of ways. The most common are by *covalent* bonding (as between the carbon atoms of the diamond crystal) and by *ionic* bonding (as in a NaCl crystal). Often the bonds are partially covalent and partially ionic. Our discussion of these bonds earlier in this Chapter for molecules applies equally well here to solids.

Let us look for a moment at the NaCl crystal of Fig. 29-20. Each Na⁺ ion feels an attractive Coulomb potential due to each of the six "nearest" neighbor" Cl⁻ ions surrounding it. Note that one Na⁺ does not "belong" exclusively to one Cl⁻, so we must not think of ionic solids as consisting of individual molecules. Each Na⁺ also feels a repulsive Coulomb potential due to other $Na⁺$ ions, although this is weaker since the $Na⁺$ ions are farther away.

A different type of bond, not discussed in Section 29–1, occurs in metals. Metal atoms have relatively loosely held outer electrons. Metallic bond theories propose that in a metallic solid, these outer electrons roam rather freely among all the metal atoms which, without their outer electrons, act like positive ions. The electrostatic attraction between the metal ions and this negative electron "gas" is believed to be, at least in part, responsible for holding the solid together. The binding energy of metal bonds is typically 1 to 3 eV , somewhat weaker than ionic or covalent bonds (5 to 10eV in solids). The "free electrons" are responsible for the high electrical and thermal conductivity of metals. This theory also nicely accounts for the shininess of smooth metal surfaces: the free electrons can vibrate at any frequency, so when light of a range of frequencies falls on a metal, the electrons can vibrate in response and reemit light of those same frequencies. Hence, the reflected light will consist largely of the same frequencies as the incident light. Compare this to nonmetallic materials that have a distinct color—the atomic electrons exist only in certain energy states, and when white light falls on them, the atoms absorb at certain frequencies, and reflect other frequencies which make up the color we see.

Here is a brief comparison of important strong bonds:

- ionic: an electron is stolen from one atom by another
- covalent: electrons are shared by atoms within a single molecule
- · metallic: electrons are shared by all atoms in the metal

The atoms or molecules of some materials, such as the noble gases, can form only weak bonds with each other. As we saw in Section 29–3, weak bonds have very low binding energies and would not be expected to hold atoms together as a liquid or solid at room temperature. The noble gases condense only at very low temperatures, where the atomic (thermal) kinetic energy is small and the weak attraction can then hold the atoms together.

29-6 Band Theory of Solids

We saw in Section 29–1 that when two hydrogen atoms approach each other, the wave functions overlap, and the two 1s states (one for each atom) divide into two states of different energy. (As we saw, only one of these states, $S = 0$, has low enough energy to give a bound H_2 , molecule.) Figure 29–21a shows this situation for 1s and 2s states for two atoms: as the two atoms get closer (toward the left on the graph), the 1s and 2s states split into two levels. If six atoms come together, as in Fig. 29-21b, each of the states splits into six levels. If a large number of atoms come together to form a solid, then each of the original atomic levels becomes a **band** as shown in Fig. 29–21c. The energy levels are so close together in each band that they seem essentially continuous. This is why the spectrum of heated solids (Section $27-2$) appears continuous.

FIGURE 29-21 The splitting of 1s and 2s atomic energy levels as (a) two atoms approach each other (the atomic separation decreases toward the left on the graph); (b) the same for six atoms, and (c) for many atoms when they come together to form a solid.

The crucial aspect of a good conductor is that the highest energy band containing electrons is only partially filled. Consider sodium, for example, whose energy bands are shown in Fig. 29–22. The 1s, 2s, and 2p bands are full (just as in a Na atom) and don't concern us. The 3s band, however, is only half full. To see why, recall that the exclusion principle stipulates that in an atom, only two electrons can be in the 3s state, one with spin up and one with spin down. These two states have slightly different energy. For a solid consisting of N atoms, the 3s band will contain 2N possible energy states. A sodium atom has a single 3s electron, so in a sample of sodium metal containing N atoms, there are N electrons in the 3s band, and N unoccupied states. When a potential difference is applied across the metal, electrons can respond by accelerating and increasing their energy, since there are plenty of unoccupied states of slightly higher energy available. Hence, a current flows readily and sodium is a good conductor. The characteristic of all good conductors is that the highest energy band is only partially filled, or two bands overlap so that unoccupied states are available. An example of the latter is magnesium, which has two 3s electrons, so its 3s band is filled. But the unfilled $3p$ band overlaps the $3s$ band in energy, so there are lots of available states for the electrons to move into. Thus magnesium, too, is a good conductor.

In a material that is a good **insulator**, on the other hand, the highest band containing electrons, called the **valence band**, is completely filled. The next highest energy band, called the **conduction band**, is separated from the valence band by a "forbidden" **energy gap** (or **band gap**), E_g , of typically 5 to 10 eV. So at room temperature (300 K) , where thermal energies (that is, average kinetic energy—see Chapter 13) are on the order of $\frac{3}{2}kT \approx 0.04$ eV, almost no electrons can acquire the 5 eV needed to reach the conduction band. When a potential difference is applied across the material, no available states are accessible to the electrons, and no current flows. Hence, the material is a good insulator.

Conductors

FIGURE 29-23 Energy bands for (a) a conductor, (b) an insulator, which has a large energy gap E_g , and (c) a semiconductor, which has a small energy gap E_{α} . Shading represents occupied states. Pale shading in (c) represents electrons that can pass from the top of the valence band to the bottom of the conduction band due to thermal agitation at room temperature (exaggerated).

Semiconductors (pure)

Figure 29–23 compares the relevant energy bands (a) for conductors, (b) for insulators, and also (c) for the important class of materials known as semiconductors. The bands for a pure (or intrinsic) semiconductor, such as silicon or germanium, are like those for an insulator, except that the unfilled conduction band is separated from the filled valence band by a much smaller energy gap, E_{ϱ} , typically on the order of 1 eV. At room temperature, a few electrons can acquire enough thermal energy to reach the conduction band, and so a very small current may flow when a voltage is applied. At higher temperatures, more electrons have enough energy to jump the gap. Often this effect can more than offset the effects of more frequent collisions due to increased disorder at higher temperature, so the resistivity of semiconductors can *decrease* with increasing temperature (see Table 18-1). But this is not the whole story of semiconductor conduction. When a potential difference is applied to a semiconductor, the few electrons in the conduction band move toward the positive electrode. Electrons in the valence band try to do the same thing, and a few can because there are a small number of unoccupied states which were left empty by the electrons reaching the conduction band. Such unfilled electron states are called **holes**. Each electron in the valence band that fills a hole in this way as it moves toward the positive electrode leaves behind its own hole, so the holes migrate toward the negative electrode. As the electrons tend to accumulate at one side of the material, the holes tend to accumulate on the opposite side. We will look at this phenomenon in more detail in the next Section.

EXAMPLE 29-4 Calculating the energy gap. It is found that the conductivity of a certain semiconductor increases when light of wavelength 345 nm or shorter strikes it, suggesting that electrons are being promoted from the valence band to the conduction band. What is the energy gap, E_e , for this semiconductor?

APPROACH The longest wavelength (lowest energy) photon to cause an increase in conductivity has $\lambda = 345$ nm, and its energy (= hf) equals the energy gap.

SOLUTION The gap energy equals the energy of a $\lambda = 345$ -nm photon:

$$
E_{\rm g} = hf = \frac{hc}{\lambda} = \frac{(6.63 \times 10^{-34} \,\mathrm{J \cdot s})(3.00 \times 10^8 \,\mathrm{m/s})}{(345 \times 10^{-9} \,\mathrm{m})(1.60 \times 10^{-19} \,\mathrm{J/eV})} = 3.6 \,\mathrm{eV}.
$$

CONCEPTUAL EXAMPLE 29-5 Which is transparent? The energy gap for silicon is 1.14 eV at room temperature, whereas that of zinc sulfide (ZnS) is 3.6 eV. Which one of these is opaque to visible light, and which is transparent?

RESPONSE Visible light photons span energies from roughly 1.8 eV to 3.2 eV $(E = hf = hc/\lambda$ where $\lambda = 400$ nm to 700 nm and $1 \text{ eV} = 1.6 \times 10^{-19}$ J.) Light is absorbed by the electrons in a material. Silicon's energy gap is small enough to absorb these photons, thus bumping electrons well up into the conduction band, so silicon is opaque. On the other hand, zinc sulfide's energy gap is too large to absorb visible photons, so the light can pass through the material; it can be transparent.

Holes (in a semiconductor)

29-7 Semiconductors and Doping

Nearly all electronic devices today use semiconductors. The most common are silicon (Si) and germanium (Ge). An atom of silicon or germanium has four outer electrons that act to hold the atoms in the regular lattice structure of the crystal, shown schematically in Fig. 29-24a. Germanium and silicon acquire properties useful for electronics only when a tiny amount of impurity is introduced into the crystal structure (perhaps 1 part in 10^6 or 10^7). This is called **doping** the semiconductor. Two kinds of doped semiconductor can be made, depending on the type of impurity used. If the impurity is an element whose atoms have five outer electrons, such as arsenic, we have the situation shown in Fig. 29–24b, with the arsenic atoms holding positions in the crystal lattice where normally silicon atoms would be. Only four of arsenic's electrons fit into the bonding structure. The fifth does not fit in and can move relatively freely, somewhat like the electrons in a conductor. Because of this small number of extra electrons, a doped semiconductor becomes slightly conducting. The density of conduction electrons in an intrinsic (undoped) semiconductor at room temperature is very low, usually less than 1 per $10⁹$ atoms. With an impurity concentration of 1 in 10^6 or 10^7 when doped, the conductivity will be much higher and it can be controlled with great precision. An arsenic-doped silicon crystal is called an *n*-type semiconductor because *negative* charges (electrons) carry the electric current.

(a) Four (outer) electrons surround each silicon atom. (b) Silicon crystal doped with a small percentage of arsenic atoms: the extra electron doesn't fit into the crystal lattice and so is free to move about. This is an n -type semiconductor.

In a p -type semiconductor, a small percentage of semiconductor atoms are replaced by atoms with three outer electrons—such as gallium. As shown in Fig. 29–25a, there is a "hole" in the lattice structure near a gallium atom since it has only three outer electrons. Electrons from nearby silicon atoms can jump into this hole and fill it. But this leaves a hole where that electron had previously been, Fig. 29–25b. The vast majority of atoms are silicon, so holes are almost always next to a silicon atom. Since silicon atoms require four outer electrons to be neutral, this means that there is a net positive charge at the hole. Whenever an electron moves to fill a hole, the positive hole is then at the previous position of that electron. Another electron can then fill this hole, and the hole thus moves to a new location; and so on. This type of semiconductor is called p -type because it is the positive holes that seem to carry the electric current. Note, however, that both p -type and n -type semiconductors have no net charge on them.

 p -type

CAUTION

p-type semiconductors act as $though + charges move - but$ electrons actually do the moving

Holes are positive

FIGURE 29-25 A *p*-type semiconductor, galliumdoped silicon. (a) Gallium has only three outer electrons, so there is an empty spot, or *hole* in the structure. (b) Electrons from silicon atoms can jump into the hole and fill it. As a result, the hole moves to a new location (to the right in this figure), to where the electron used to be.

*SECTION 29-7 Semiconductors and Doping 827

Doped semiconductors

 n -type

FIGURE 29-24 Two-dimensional representation of a silicon crystal.

According to the band theory (Section 29–6), in a doped semiconductor the impurity provides additional energy states between the bands as shown in Fig. $29-26$. In an *n*-type semiconductor, the impurity energy level lies just below the conduction band, Fig. 29–26a. Electrons in this energy level need only about 0.05 eV in Si (even less in Ge) to reach the conduction band; this is on the order of the thermal energy, $\frac{3}{2}kT$ (= 0.04 eV at 300 K), so transitions occur readily at room temperature. This energy level can thus supply electrons to the conduction band, so it is called a **donor** level. In p -type semiconductors, the impurity energy level is just above the valence band (Fig. 29–26b). It is called an **acceptor** level because electrons from the valence band can easily jump into it. Positive holes are left behind in the valence band, and as other electrons move into these holes, the holes move about as discussed earlier.

29-8 Semiconductor Diodes

Semiconductor diodes and transistors are essential components of modern electronic devices. The miniaturization achieved today allows many thousands of diodes, transistors, resistors, and so on, to be placed on a single *chip* less than a millimeter on a side. We now discuss, briefly and qualitatively, the operation of diodes and transistors.

pn junction diode

FIGURE 29-27 Schematic diagram showing how a semiconductor diode operates. Current flows when the voltage is connected in forward bias, as in (a), but not when connected in reverse bias, as in (b).

When an *n*-type semiconductor is joined to a *p*-type, a *pn* junction diode is formed. Separately, the two semiconductors are electrically neutral. When joined, a few electrons near the junction diffuse from the n -type into the p -type semiconductor, where they fill a few of the holes. The n -type is left with a positive charge, and the p -type acquires a net negative charge. Thus a potential difference is established, with the *n* side positive relative to the *p* side, and this prevents further diffusion of electrons.

If a battery is connected to a diode with the positive terminal to the p side and the negative terminal to the *n* side as in Fig. $29-27a$, the externally applied voltage opposes the internal potential difference and the diode is said to be **forward biased.** If the voltage is great enough (about 0.3 V for Ge, 0.6 V for Si at room temperature), a current will flow. The positive holes in the p -type semiconductor are repelled by the positive terminal of the battery, and the electrons in the n -type are repelled by the negative terminal of the battery. The holes and electrons meet at the junction, and the electrons cross over and fill the holes. A current is flowing. Meanwhile, the positive terminal of the battery is continually pulling electrons off the p end, forming new holes, and electrons are being supplied by the negative terminal at the n end. Consequently, a large current flows through the diode.

When the diode is **reverse biased**, as in Fig. 29–27b, the holes in the p end are attracted to the battery's negative terminal and the electrons in the n end are attracted to the positive terminal. The current carriers do not meet near the junction and, ideally, no current flows.

A graph of current versus voltage for a typical diode is shown in Fig. 29–28. As can be seen, a real diode does allow a small amount of reverse current to flow. \dagger For most practical purposes, this is negligible.

[†]At room temperature it is a few μ A in Ge, and a few pA in Si. The reverse current increases rapidly with temperature, however, and may render a diode ineffective above 200°C.

FIGURE 29-28 Current through a diode as a function of applied voltage.

EXAMPLE 29-6 A diode. The diode whose current-voltage characteristics are shown in Fig. 29–28 is connected in series with a 4.0-V battery and a resistor. If a current of 15 mA is to pass through the diode, what resistance must the resistor have?

APPROACH We use Fig. 29-28, where we see that the voltage drop across the diode is about 0.7 V when the current is 15 mA. Then we use simple circuit analysis and Ohm's law (Chapters 18 and 19).

SOLUTION The voltage drop across the resistor is $4.0 \text{ V} - 0.7 \text{ V} = 3.3 \text{ V}$, so $R = V/I = (3.3 \text{ V})/(1.5 \times 10^{-2} \text{ A}) = 220 \Omega.$

The symbol for a diode is

$$
\textcolor{red}{\bigcirc \hspace{-0.25cm}{\circ}}
$$

[diode]

where the arrow represents the direction conventional $(+)$ current flows readily.

Since a pn junction diode allows current to flow only in one direction (as long as the voltage is not too high), it can serve as a rectifier—to change ac into dc. A simple rectifier circuit is shown in Fig. 29–29a. The ac source applies a voltage across the diode alternately positive and negative. Only during half of each cycle will a current pass through the diode; only then is there a current through the resistor R. Hence, a graph of the voltage V_{ab} across R as a function of time looks like the output voltage shown in Fig. $29-29b$. This **half-wave rectification** is not exactly dc, but it is unidirectional. More useful is a full-wave rectifier circuit, which uses two diodes (or sometimes four) as shown in Fig. 29–30a. At any given instant, either one diode or the other will conduct current to the right. Therefore, the output across the load resistor R will be as shown in Fig. 29–30b. Actually this is the voltage if the capacitor C were not in the circuit. The capacitor tends to store charge and, if the time constant RC is sufficiently long, helps to smooth out the current as shown in Fig. 29-30c. (The variation in output shown in Fig. 29-30c is called ripple voltage.)

Rectifier circuits are important because most line voltage in buildings is ac, and most electronic devices require a dc voltage for their operation. Hence, diodes are found in nearly all electronic devices including radio and TV sets, calculators, and computers.

FIGURE $29-29$ (a) A simple (half-wave) rectifier circuit using a semiconductor diode. (b) AC source input voltage, and output voltage across R , as functions of time.

FIGURE 29-30 (a) Full-wave-rectifier circuit (including a transformer so the magnitude of the voltage can be changed). (b) Output voltage in the absence of capacitor C . (c) Output voltage with the capacitor in the circuit.

PHYSICS APPLIED LED

Another useful device is a light-emitting diode (LED), invented in the 1960s. When a *pn* junction is forward biased, a current begins to flow. Electrons cross from the *n* region into the *p* region and combine with holes, and a photon can be emitted with an energy approximately equal to the band gap, E_g (see Figs. 29–23c and 29–26). Often the energy, and hence the wavelength, is in the red region of the visible spectrum, producing the familiar LED displays on VCRs, CD players, car instrument panels, digital clocks, and so on. Infrared (i.e., nonvisible) LEDs are used in remote controls for TV, DVDs, and stereos. New types of LEDs emit other colors, and LED "bulbs" are beginning to replace other types of lighting in applications such as flashlights, traffic signals, car brake lights, and outdoor signs, billboards, and theater displays. LED bulbs, sometimes called solid-state lighting, are costly, but they offer advantages: they are long-lived, efficient, and rugged. LED traffic lights, for example, last 5 to 10 times longer than traditional incandescent bulbs, and use only 20% of the energy for the same light output. As car brake lights, they light up a fraction of a second sooner, allowing a driver an extra 5 or 6 meters (15–20 ft) more stopping distance at highway speeds.

Solar cells and photodiodes

Solar cells and **photodiodes** (Section 27-3) are *pn* junctions used in the reverse way. Photons are absorbed, creating electron-hole pairs if the photon energy is greater than the band gap energy, E_e . The created electrons and holes produce a current that, when connected to an external circuit, becomes a source of emf and power. Particle detectors (Section 30-13) operate similarly.

A diode is called a nonlinear device because the current is not proportional to the voltage. That is, a graph of current versus voltage (Fig. $29-28$) is not a straight line, as it is for a resistor (which ideally is linear). Transistors are also nonlinear devices.

29-9 Transistors and Integrated Circuits

Transistors

A simple junction transistor consists of a crystal of one type of doped semiconductor sandwiched between two crystals of the opposite type. Both npn and pnp transistors are made, and they are shown schematically in Fig. 29–31a. The three semiconductors are given the names collector, base, and emitter. The symbols for npn and pnp transistors are shown in Fig. 29-31b. The arrow is always placed on the emitter and indicates the direction of (conventional) current flow in normal operation.

The operation of a transistor can be analyzed qualitatively—very briefly as follows. Consider an *npn* transistor connected as shown in Fig. 29–32. A voltage V_{CE} is maintained between the collector and emitter by the battery \mathscr{E}_C . The voltage applied to the base is called the base bias voltage, V_{BE} . If V_{BE} is positive, conduction electrons in the emitter are attracted into the base. Since the base region is very thin (perhaps $1 \mu m$), most of these electrons flow right across into the collector, which is maintained at a positive voltage. A large current, I_c , flows between collector and emitter and a much smaller current, I_B ,

FIGURE 29-31 (a) Schematic diagram of npn and pnp transistors. (b) Symbols for npn and pnp transistors.

FIGURE 29-32 An *npn* transistor used as an amplifier.

830 CHAPTER 29 **Molecules and Solids** through the base. A small variation in the base voltage due to an input signal causes a large change in the collector current and therefore a large change in the voltage drop across the output resistor R_C . Hence a transistor can *amplify* a small signal into a larger one.

Transistors are the basic elements in modern electronic **amplifiers** of all sorts. In digital circuits, where "off" and "on" (or zero and one) are basic, transistors can act like a "gate" or switch. That is, they let current pass ("on") or they block it ("off").

A pnp transistor operates like an npn, except that holes move instead of electrons. The collector voltage is negative, and so is the base voltage in normal operation.

Transistors were a great advance in miniaturization of electronic circuits. Although individual transistors are very small compared to the once used vacuum tubes, they are huge compared to **integrated circuits** or **chips** (see photo at start of this Chapter). Tiny amounts of impurities can be placed at particular locations within a single silicon crystal. These can be arranged to form diodes, transistors, and resistors (undoped semiconductors). Capacitors and inductors can also be formed, although they are often connected separately. A tiny chip, a few mm on a side, may contain millions of transistors and other circuit elements. Integrated circuits are the heart of computers, television, calculators, cameras, and the electronic instruments that control aircraft, space vehicles, and automobiles. The "miniaturization" produced by integrated circuits not only allows extremely complicated circuits to be placed in a small space, but also has allowed a great increase in the speed of operation of, say, computers, because the distances the electronic signals travel are so tiny.

Summary

Quantum mechanics explains the bonding together of atoms to form molecules. In a covalent bond, the electron clouds of two or more atoms overlap because of constructive interference between the electron waves. The positive nuclei are attracted to this concentration of negative charge between them, forming the bond.

An ionic bond is an extreme case of a covalent bond in which one or more electrons from one atom spend much more time around the other atom than around their own. The atoms then act as oppositely charged ions that attract each other, forming the bond.

These strong bonds hold molecules together, and also hold atoms and molecules together in solids. Also important are weak bonds (or van der Waals bonds), which are generally dipole attractions between molecules.

When atoms combine to form molecules, the energy levels of the outer electrons are altered because they now interact with each other. Additional energy levels also become possible because the atoms can vibrate with respect to each other, and the molecule as a whole can rotate. The energy levels for both vibrational and rotational motion are quantized, and are very close together (typically, 10^{-1} eV to 10^{-3} eV apart). Each atomic energy level thus becomes a set of closely spaced levels corresponding to the vibrational and rotational motions. Transitions from one level to another appear as many very closely spaced lines. The resulting spectra are called band spectra.

The quantized rotational energy levels are given by

$$
E_{\text{rot}} = L(L+1)\frac{\hbar^2}{2I}, \qquad L = 0, 1, 2, \cdots, \qquad (29-1)
$$

where I is the moment of inertia of the molecule.

Amplifiers

Digital circuits and gates

The energy levels for vibrational motion are given by

 $E_{\text{vib}} = (\nu + \frac{1}{2})hf, \qquad \nu = 0, 1, 2, \cdots,$ (29-3)

where f is the classical natural frequency of vibration for the molecule. Transitions between energy levels are subject to the selection rules $\Delta L = \pm 1$ and $\Delta \nu = \pm 1$.

Some solids are bound together by covalent and ionic bonds, just as molecules are. In metals, the electrostatic force between free electrons and positive ions helps form the metallic bond.

In a crystalline solid, the possible energy states for electrons are arranged in bands. Within each band the levels are very close together, but between the bands there may be forbidden energy gaps. Good conductors are characterized by the highest occupied band (the conduction band) being only partially full, so there are many accessible states available to electrons to move about and accelerate when a voltage is applied. In a good insulator, the highest occupied energy band (the **valence band**) is completely full, and there is a large energy gap (5 to 10 eV) to the next highest band, the *conduction band*. At room temperature, molecular kinetic energy (thermal energy) available due to collisions is only about 0.04 eV, so almost no electrons can jump from the valence to the conduction band. In a semiconductor, the gap between valence and conduction bands is much smaller, on the order of 1 eV, so a few electrons can make the transition from the essentially full valence band to the nearly empty conduction band.

In a **doped** semiconductor, a small percentage of impurity atoms with five or three valence electrons replace a few of the normal silicon atoms with their four valence electrons. A fiveelectron impurity produces an n -type semiconductor with negative electrons as carriers of current. A three-electron impurity

produces a *p*-type semiconductor in which positive holes carry the current. The energy level of impurity atoms lies slightly below the conduction band in an n -type semiconductor, and acts as a **donor** from which electrons readily pass into the conduction band. The energy level of impurity atoms in a p -type semiconductor lies slightly above the valence band and acts as an acceptor level, since electrons from the valence band easily reach it, leaving holes behind to act as charge carriers.

A semiconductor **diode** consists of a pn junction and allows current to flow in one direction only; it can be used as a rectifier to change ac to dc. Common transistors consist of three semiconductor sections, either as *pnp* or *npn*. Transistors can amplify electrical signals and find many other uses. An integrated circuit consists of a tiny semiconductor crystal or chip on which many transistors, diodes, resistors, and other circuit elements have been constructed using careful placement of impurities.

Questions

- *1. What type of bond would you expect for (a) the N₂ molecule, (b) the HCl molecule, (c) Fe atoms in a solid?
- *2. Describe how the molecule CaCl₂ could be formed.
- *3. Does the H_2 molecule have a permanent dipole moment? Does O_2 ? Does H_2O ? Explain.
- *4. Although the molecule H_3 is not stable, the ion H_3^+ is. Explain, using the Pauli exclusion principle.
- *5. The energy of a molecule can be divided into four categories. What are they?
- *6. Would you expect the molecule H_2 ⁺ to be stable? If so, where would the single electron spend most of its time?
- *7. Explain why the carbon atom ($Z = 6$) usually forms four bonds with hydrogen-like atoms.
- *8. If conduction electrons are free to roam about in a metal, why don't they leave the metal entirely?
- *9. Explain why the resistivity of metals increases with temperature whereas the resistivity of semiconductors may decrease with increasing temperature.
- * 10. Figure 29-33 shows a "bridge-type" full-wave rectifier. Explain how the current is rectified and how current flows during each half cycle.

Problems

* 29-1 to 29-3 Molecular Bonds

- ^{*} 1. (I) Estimate the binding energy of a KCl molecule by calculating the electrostatic potential energy when the K^+ and Cl^- ions are at their stable separation of 0.28 nm. Assume each has a charge of magnitude 1.0e.
- $*$ 2. (II) The measured binding energy of KCl is 4.43 eV. From the result of Problem 1, estimate the contribution to the binding energy of the repelling electron clouds at the equilibrium distance $r_0 = 0.28$ nm.
- $*$ 3. (II) Estimate the binding energy of the H_2 molecule, assuming the two H nuclei are 0.074 nm apart and the two electrons spend 33% of their time midway between them.
- *4. (II) Binding energies are often measured experimentally in kcal per mole, and then the binding energy in eV per molecule is calculated from that result. What is the conversion factor in going from kcal per mole to eV per molecule? What is the binding energy of KCl $(= 4.43 \text{ eV})$ in kcal per mole?
- $*$ 11. Compare the resistance of a pn junction diode connected in forward bias to its resistance when connected in reverse bias.
- * 12. Explain how a transistor could be used as a switch.
- $*$ 13. What is the main difference between *n*-type and *p*-type semiconductors?
- * 14. Describe how a *pnp* transistor can operate as an amplifier.
- * 15. In a transistor, the base-emitter junction and the base-collector junction are essentially diodes. Are these junctions reverse-biased or forward-biased in the application shown in Fig. 29-32?
- * 16. A transistor can amplify an electronic signal, meaning it can increase the power of an input signal. Where does it get the energy to increase the power?
- * 17. A silicon semiconductor is doped with phosphorus. Will these atoms be donors or acceptors? What type of semiconductor will this be?
- * 18. Do diodes and transistors obey Ohm's law? Explain.
- * 19. Can a diode be used to amplify a signal? Explain.

- $*$ 5. (III) (a) Apply reasoning similar to that in the text for the $S = 0$ and $S = 1$ states in the formation of the H₂ molecule to show why the molecule He_2 is not formed. (b) Explain why the He_2 ⁺ molecular ion *could* form. (Experiment shows it has a binding energy of 3.1 eV at $r_0 = 0.11$ nm.)
- * 29-4 Molecular Spectra
- *6. (I) Show that the quantity \hbar^2/I has units of energy.
- *7. (II) The so-called "characteristic rotational energy," $\hbar^2/2I$, for N₂ is 2.48 \times 10⁻⁴ eV. Calculate the N₂ bond length.
- * 8. (II) (a) Calculate the characteristic rotational energy, $\hbar^2/2I$, for the O_2 molecule whose bond length is 0.121 nm. (b) What are the energy and wavelength of photons emitted in a $L = 2$ to $L = 1$ transition?
- * 9. (II) The equilibrium separation of H atoms in the H_2 molecule is 0.074 nm (Fig. 29–8). Calculate the energies and wavelengths of photons for the rotational transitions (a) $L = 1$ to $L = 0$, (b) $L = 2$ to $L = 1$, and (c) $L = 3$ to $L = 2$.
- *10. (II) Calculate the bond length for the NaCl molecule given that three successive wavelengths for rotational transitions are 23.1 mm, 11.6 mm, and 7.71 mm.
- $*11.$ (III) (*a*) Use the curve of Fig. 29–17 to estimate the stiffness constant k for the H_2 molecule. (Recall that $PE = \frac{1}{2}kx^2$.) (b) Then estimate the fundamental wavelength for vibrational transitions using the classical formula (Chapter 11), but use only $\frac{1}{2}$ the mass of an H atom (because both H atoms move).

* 29-5 Bonding in Solids

- *12. (II) The spacing between "nearest neighbor" Na and Cl ions in a NaCl crystal is 0.24 nm. What is the spacing between two nearest neighbor Na ions?
- $*13.$ (II) Common salt, NaCl, has a density of 2.165 g/cm³. The molecular weight of NaCl is 58.44. Estimate the distance between nearest neighbor Na and Cl ions. [Hint: each ion can be considered to have one "cube" or "cell" of side s (our unknown) extending out from it.]
- *14. (II) Repeat Problem 13 for KCl whose density is $1.99 g/cm³$.

* 29-6 Band Theory of Solids

- *15. (I) Explain on the basis of energy bands why the sodium chloride crystal is a good insulator. [Hint: consider the shells of $Na⁺$ and $Cl⁻$ ions.]
- *16. (I) A semiconductor, bombarded with light of slowly increased frequency, begins to conduct when the wavelength of light is 640 nm. Estimate the size of the energy gap E_{α} .
- * 17. (II) Calculate the longest-wavelength photon that can cause an electron in silicon ($E_g = 1.1$ eV) to jump from the valence band to the conduction band.
- *18. (II) The energy gap between valence and conduction bands in germanium is 0.72 eV. What range of wavelengths can a photon have to excite an electron from the top of the valence band into the conduction band?
- *19. (II) The energy gap E_g in germanium is 0.72 eV. When used as a photon detector, roughly how many electrons can be made to jump from the valence to the conduction band by the passage of a 760-keV photon that loses all its energy in this fashion?
- $*$ 20. (III) We saw that there are 2N possible electron states in the $3s$ band of Na, where N is the total number of atoms. How many possible electron states are there in the (a) 2s band, (b) $2p$ band, and (c) $3p$ band? (d) State a general formula for the total number of possible states in any given electron band.

General Problems

 $*31$. Estimate the binding energy of the H₂ molecule by calculating the difference in kinetic energy of the electrons between when they are in separate atoms and when they are in the molecule, using the uncertainty principle. Take Δx for the electrons in the separated atoms to be the radius of the first Bohr orbit, 0.053 nm, and for the molecule take Δx to be the separation of the nuclei, 0.074 nm. [*Hint*: let $p \approx \Delta p_x$.]

* 29-7 Semiconductors and Doping

* 21. (III) Suppose that a silicon semiconductor is doped with phosphorus so that one silicon atom in $10⁶$ is replaced by a phosphorus atom. Assuming that the "extra" electron in every phosphorus atom is donated to the conduction band, by what factor is the density of conduction electrons increased? The density of silicon is 2330 kg/m^3 , and the density of conduction electrons in pure silicon is about 10^{16} m⁻³ at room temperature.

* 29-8 Diodes

- * 22. (I) At what wavelength will an LED radiate if made from a material with an energy gap $E_g = 1.4 \text{ eV}$?
- * 23. (I) If an LED emits light of wavelength $\lambda = 650$ nm, what is the energy gap (in eV) between valence and conduction bands?
- * 24. (II) A silicon diode, whose current-voltage characteristics are given in Fig. 29-28, is connected in series with a battery and a 960- Ω resistor. What battery voltage is needed to produce a 12-mA current?
- * 25. (II) Suppose that the diode of Fig. 29-28 is connected in series to a 100- Ω resistor and a 2.0-V battery. What current flows in the circuit? [Hint: draw a line on Fig. 29-28 representing the current in the resistor as a function of the voltage across the diode. The intersection of this line with the characteristic curve will give the answer.]
- * 26. (II) Sketch the resistance as a function of current, for $V > 0$, for the diode shown in Fig. 29–28.
- * 27. (II) An ac voltage of 120 V rms is to be rectified. Estimate very roughly the average current in the output resistor $$ $(25 \text{ k}\Omega)$ for (a) a half-wave rectifier (Fig. 29–29), and (b) a full-wave rectifier (Fig. 29–30) without capacitor.
- * 28. (III) A silicon diode passes significant current only if the forward-bias voltage exceeds about 0.6 V. Make a rough estimate of the average current in the output resistor R of (a) a half-wave rectifier (Fig. $29-29$), and (b) a full-wave rectifier (Fig. 29-30) without a capacitor. Assume that $R = 150 \Omega$ in each case and that the ac voltage is 12.0 V rms in each case.
- * 29. (III) A 120-V rms 60-Hz voltage is to be rectified with a full-wave rectifier (Fig. 29-30), where $R = 21 \text{ k}\Omega$, and $C = 25 \mu F$. (a) Make a rough estimate of the average current. (b) What happens if $C = 0.10 \,\mu\text{F}$? [*Hint*: see Section 19–6.]

29-9 Transistors

- * 30. (II) From Fig. 29–32, write an equation for the relationship between the base current (I_B) , the collector current (I_C) , and the emitter current (I_E) , not labeled in the figure).
- **32.** The average translational kinetic energy of an atom or molecule is about $\overline{KE} = \frac{3}{2}kT$ (Eq. 13-8), where $k = 1.38 \times 10^{-23}$ J/K is Boltzmann's constant. At what temperature T will \overline{KE} be on the order of the bond energy (and hence the bond likely to be broken by thermal motion) for (a) a covalent bond of binding energy 4.5 eV (say H_2), and (b) a "weak" hydrogen bond of binding energy 0.15 eV?
- * 33. In the ionic salt KF, the separation distance between ions is about 0.27 nm. (a) Estimate the electrostatic potential energy between the ions assuming them to be point charges (magnitude $1e$). (b) It is known that F releases 4.07 eV of energy when it "grabs" an electron, and 4.34 eV is required to ionize K. Find the binding energy of KF relative to free K and F atoms, neglecting the energy of repulsion.
- * 34. Consider a monoatomic solid with a weakly bound cubic lattice, with each atom connected to six neighbors, each bond having a binding energy of 3.9×10^{-3} eV. When this solid melts, its latent heat of fusion goes directly into breaking the bonds between the atoms. Estimate the latent heat of fusion for this solid, in J/kg. [Hint: show that in a simple cubic lattice (Fig. 29-34), there are *three* times as many bonds as there are atoms, when the number of atoms is large.]

FIGURE 29-34 Problem 34.

- $*35$. For O₂ with a bond length of 0.121 nm, what is the moment of inertia about the center of mass?
- *36. A diatomic molecule is found to have an activation energy of 1.4 eV. When the molecule is disassociated, 1.6 eV of energy is released. Draw a potential energy curve for this molecule.
- * 37. When EM radiation is incident on diamond, it is found that light with wavelengths shorter than 226 nm will cause the diamond to conduct. What is the energy gap between the valence band and the conduction band for diamond?
- *38. A TV remote control emits IR light. If the detector on the TV set is not to react to visible light, could it make use of silicon as a "window" with its energy gap $E_g = 1.14 \text{ eV}$? What is the shortest-wavelength light that can strike silicon without causing electrons to jump from the valence band to the conduction band?
- *39. For an arsenic donor atom in a doped silicon semiconductor, assume that the "extra" electron moves in a Bohr orbit about the arsenic ion. For this electron in the ground state, take into account the dielectric constant $K = 12$ of the Si lattice (which represents the weakening of the Coulomb force due to all the other atoms or ions in the lattice), and estimate (a) the binding energy, and (b) the orbit radius for this extra electron. [Hint: substitute $\epsilon = K \epsilon_0$ in Coulomb's law; see Section 17-8.]
- * 40. Most of the Sun's radiation has wavelengths shorter than 1000 nm. For a solar cell to absorb all this, what energy gap ought the material have?
- * 41. For a certain semiconductor, the longest wavelength radiation that can be absorbed is 1.92 mm. What is the energy gap in this semiconductor?
- * 42. Green and blue LEDs became available many years after red LEDs were first developed. Approximately what energy gaps would you expect to find in green (525 nm) and in blue (465 nm) LEDs?
- *43. A zener diode voltage regulator is shown in Fig. 29-35. Suppose that $R = 1.80 \text{ k}\Omega$ and that the diode breaks down at a reverse voltage of 130 V. (The current increases rapidly at this point, as shown on the far left of Fig. 29-28 at a voltage of -12 V on that diagram.) The diode is rated at a maximum current of 120 mA. (a) If $R_{load} = 15.0 \text{ k}\Omega$, over what range of supply voltages will the circuit maintain the output voltage at 130 V ? (b) If the supply voltage is 200 V, over what range of load resistance will the voltage be regulated?

Answers to Exercises

A: 1.30 mm, 0.87 mm, 0.65 mm.

B: 0.81 eV.

This archeologist has unearthed the remains of a sea-turtle within an ancient man-made stone circle. Carbon dating of the remains can tell her when humans inhabited the site.

In this Chapter we begin our discussion of nuclear physics including the properties of nuclei, the various forms of radioactivity, and how radioactive decay can be used in a variety of fields to determine the age of old objects, from bones and trees to rocks and other mineral substances, and obtain information on the history of the Earth.

Nuclear Physics and Radioactivity

n the early part of the twentieth century, Rutherford's experiments led to the idea that at the center of an atom there is a tiny but massive nucleus. At The same time that the quantum theory was being developed and scientists were attempting to understand the structure of the atom and its electrons, investigations into the nucleus itself had also begun. In this Chapter and the next, we take a brief look at nuclear physics.

Structure and Properties of the Nucleus 30–1

An important question for physicists was whether the nucleus had a structure, and what that structure might be. It turns out that the nucleus is a complicated entity and is not fully understood even today. However, by the early 1930s, a model of the nucleus had been developed that is still useful. According to this model, a nucleus is considered to be an aggregate of two types of particles: protons and neutrons. (These "particles" also have wave properties, but for ease of visualization and language, we often refer to them simply as "particles.") A **proton** is the nucleus of the simplest atom, hydrogen. It has a positive charge $(= +e = +1.60 \times 10^{-19} \text{ C}$, the same magnitude as for the electron) and a mass

Proton

$$
m_p = 1.67262 \times 10^{-27}
$$
 kg.

The neutron, whose existence was ascertained in 1932 by the English physicist James Chadwick (1891–1974), is electrically neutral $(a = 0)$, as its name implies. Its mass is very slightly larger than that of the proton:

Neutron

Nucleons

 $m_n = 1.67493 \times 10^{-27}$ kg.

These two constituents of a nucleus, neutrons and protons, are referred to collectively as nucleons.

 Z and A

Although the hydrogen nucleus consists of a single proton alone, the nuclei of all other elements consist of both neutrons and protons. The different nuclei are often referred to as nuclides. The number of protons in a nucleus (or nuclide) is called the atomic number and is designated by the symbol Z. The total number of nucleons, neutrons plus protons, is designated by the symbol A and is called the **atomic mass number**, or sometimes simply **mass number**. This name is used since the mass of a nucleus is very closely A times the mass of one nucleon. A nuclide with 7 protons and 8 neutrons thus has $Z = 7$ and $A = 15$. The **neutron number** N is $N = A - Z$.

To specify a given nuclide, we need give only A and Z . A special symbol is commonly used which takes the form

 $^{A}_{Z}X$.

where X is the chemical symbol for the element (see Appendix B, and the periodic table inside the back cover), \vec{A} is the atomic mass number, and \vec{Z} is the atomic number. For example, $^{15}_{7}N$ means a nitrogen nucleus containing 7 protons and 8 neutrons for a total of 15 nucleons. In a neutral atom, the number of electrons orbiting the nucleus is equal to the atomic number Z (since the charge on an electron has the same magnitude but opposite sign to that of a proton). The main properties of an atom, and how it interacts with other atoms, are largely determined by the number of electrons. Hence Z determines what kind of atom it is: carbon, oxygen, gold, or whatever. It is redundant to specify both the symbol of a nucleus and its atomic number Z as described above. If the nucleus is nitrogen, for example, we know immediately that $Z = 7$. The subscript Z is thus sometimes dropped and $^{15}_{7}N$ is then written simply ¹⁵N; in words we say "nitrogen fifteen."

Isotopes

For a particular type of atom (say, carbon), nuclei are found to contain different numbers of neutrons, although they all have the same number of protons. For example, carbon nuclei always have 6 protons, but they may have 5, 6, 7, 8, 9, or 10 neutrons. Nuclei that contain the same number of protons but different numbers of neutrons are called **isotopes**. Thus, ${}^{11}_{6}C$, ${}^{12}_{6}C$, ${}^{13}_{6}C$, ${}^{14}_{6}C$, ${}^{15}_{6}C$, and $^{16}_{6}$ C are all isotopes of carbon. The isotopes of a given element are not all equally common. For example, 98.9% of naturally occurring carbon (on Earth) is the isotope $^{12}_{6}C$, and about 1.1% is $^{13}_{6}C$. These percentages are referred to as the **natural abundances**.[†] Many isotopes that do not occur naturally can be produced in the laboratory by means of nuclear reactions (more on this later). Indeed, all elements beyond uranium $(Z > 92)$ do not occur naturally on Earth and are only produced artificially, as are many nuclides with $Z \le 92$.

The approximate size of nuclei was determined originally by Rutherford from the scattering of charged particles by thin metal foils. We cannot speak about a definite size for nuclei because of the wave-particle duality: their spatial extent must remain somewhat fuzzy. Nonetheless a rough "size" can be measured by scattering high-speed electrons off nuclei. It is found that nuclei have a roughly spherical

[†]The mass value for each element as given in the periodic table (inside back cover) is an average weighted according to the natural abundances of its isotopes.

shape with a radius that increases with A according to the approximate formula

$$
r \approx (1.2 \times 10^{-15} \,\mathrm{m})(A^{\frac{1}{3}}).
$$

 $(30-1)$ Nuclear radii

Since the volume of a sphere is $V = \frac{4}{3}\pi r^3$, we see that the volume of a nucleus is approximately proportional to the number of nucleons, $V \propto A$. This is what we would expect if nucleons were like impenetrable billiard balls: if you double the number of balls, you double the total volume. Hence, all nuclei have nearly the same density, and it is enormous (see Example 30-2).

The metric abbreviation for 10^{-15} m is the fermi (after Enrico Fermi) or the femtometer, fm (Table 1–4 or inside the front cover). Thus 1.2×10^{-15} m = 1.2 fm or 1.2 fermis.

EXAMPLE 30-1 ESTIMATE Nuclear sizes. Estimate the diameter of the following nuclei: (a) ${}_{1}^{1}H$, (b) ${}_{20}^{40}Ca$, (c) ${}_{82}^{208}Pb$, (d) ${}_{92}^{235}U$.

APPROACH The radius r of a nucleus is related to its number of nucleons A by Eq. 30–1. The diameter $d = 2r$.

SOLUTION (a) For hydrogen, $A = 1$, Eq. 30–1 gives

$$
d =
$$
 diameter = $2r \approx 2(1.2 \times 10^{-15} \text{ m})(A^{\frac{1}{3}}) = 2.4 \times 10^{-15} \text{ m}$

since $A^{\frac{1}{3}} = 1^{\frac{1}{3}} = 1$.

(b) For calcium $d = 2r \approx (2.4 \times 10^{-15} \text{ m})(40)^{\frac{1}{3}} = 8.2 \times 10^{-15} \text{ m}$.

(c) For lead $d \approx (2.4 \times 10^{-15} \text{ m})(208)^{\frac{1}{3}} = 14 \times 10^{-15} \text{ m}$.

(d) For uranium $d \approx (2.4 \times 10^{-15} \text{ m})(235)^{\frac{1}{3}} = 15 \times 10^{-15} \text{ m}$.

The range of nuclear diameters is only from 2.4 fm to 15 fm.

NOTE Because nuclear radii vary as A^{\dagger} , the largest nuclei have a radius only about 6 times that of the smallest.

EXAMPLE 30-2 ESTIMATE Nuclear and atomic densities. Compare the density of nuclear matter to the density of normal solids.

APPROACH The density of normal liquids and solids is on the order of $10³$ to $10⁴$ kg/m³ (see Table 10–1), and because the atoms are close packed, atoms have about this density too. We therefore compare the density (mass per volume) of a nucleus to that of its atom as a whole.

SOLUTION The mass of a proton is greater than the mass of an electron by a factor 1.7×10^{-27} kg

$$
\frac{1.7 \times 10^{-31} \text{ kg}}{9.1 \times 10^{-31} \text{ kg}} \approx 2 \times 10^3.
$$

Thus, over 99.9% of the mass of an atom is in the nucleus, and for our estimate we can say the mass of the atom equals the mass of the nucleus, $m_{\text{nucl}}/m_{\text{atom}} = 1$. Atoms have a radius of about 10^{-10} m (Chapter 27) and nuclei on the order of 10^{-15} m (Eq. 30–1). Thus the ratio of nuclear density to atomic density is about

$$
\frac{\rho_{\text{nucl}}}{\rho_{\text{atom}}} = \frac{(m_{\text{nucl}}/V_{\text{nucl}})}{(m_{\text{atom}}/V_{\text{atom}})} = \left(\frac{m_{\text{nucl}}}{m_{\text{atom}}}\right) \frac{\frac{4}{3}\pi r_{\text{atom}}^3}{\frac{4}{3}\pi r_{\text{nucl}}^3} \approx (1) \frac{(10^{-10})^3}{(10^{-15})^3} = 10^{15}.
$$

The nucleus is 10^{15} times more dense than ordinary matter.

The masses of nuclei can be determined from the radius of curvature of fastmoving nuclei (as ions) in a known magnetic field using a mass spectrometer, as discussed in Section 20-11. Indeed the existence of different isotopes of the same element (different number of neutrons) was discovered using this device. Nuclear masses can be specified in **unified atomic mass units** (u). On this scale, a neutral ${}^{12}_{6}C$ atom is given the precise value 12.000000 u. A neutron then has a measured mass of 1.008665 u, a proton 1.007276 u, and a neutral hydrogen atom ${}^{1}_{1}H$ (proton plus electron) 1.007825 u. The masses of many nuclides are given in Appendix B. It should be noted that the masses in this Table, as is customary, are for the *neutral atom* (including electrons), and not for a bare nucleus.

CAUTION Masses are for neutral atom (nucleus plus electrons)

Masses are often specified using the electron-volt energy unit. This can be done because mass and energy are related, and the precise relationship is given by Einstein's equation $E = mc^2$ (Chapter 26). Since the mass of a proton is 1.67262×10^{-27} kg, or 1.007276 u, then

$$
1.0000 \, \mathbf{u} = \left(\frac{1.0000 \, \mathbf{u}}{1.007276 \, \mathbf{u}}\right) (1.67262 \times 10^{-27} \, \text{kg}) = 1.66054 \times 10^{-27} \, \text{kg};
$$

this is equivalent to an energy (see Table inside front cover) in MeV (= 10^6 eV) of

$$
E = mc^2 = \frac{(1.66054 \times 10^{-27} \text{ kg})(2.9979 \times 10^8 \text{ m/s})^2}{(1.6022 \times 10^{-19} \text{ J/eV})} = 931.5 \text{ MeV}.
$$

Thus

TABLE 20 1

Atomic mass unit and MeV

$$
1\,\mathrm{u} = 1.6605 \times 10^{-27}\,\mathrm{kg} = 931.5\,\mathrm{MeV}/c^2.
$$

The rest masses of some of the basic particles are given in Table 30–1.

Just as an electron has intrinsic spin and angular momentum quantum numbers, so too do nuclei and their constituents, the proton and neutron. Both the proton and the neutron are spin $\frac{1}{2}$ particles. A nucleus, made up of protons and neutrons, has a nuclear spin quantum number, I , that can be either integer or half integer, depending on whether it is made up of an even or an odd number of nucleons.

-2 Binding Energy and Nuclear Forces

Binding Energies

The total mass of a stable nucleus is always less than the sum of the masses of its separate protons and neutrons, as the following Example shows.

EXAMPLE 30-3 $\frac{4}{2}$ He mass compared to its constituents. Compare the mass of a ${}_{2}^{4}$ He atom to the total mass of its constituent particles.

APPROACH The ${}_{2}^{4}$ He nucleus contains 2 protons and 2 neutrons. Tables normally give the masses of neutral atoms—that is, nucleus plus its Z electrons-since this is how masses are measured. We must therefore be sure to balance out the electrons when we compare masses. Thus we use the mass of ${}_{1}^{1}$ H rather than that of a proton alone. We look up the mass of the ${}_{2}^{4}$ He atom in Appendix B (it includes the mass of 2 electrons), as well as the mass for the 2 neutrons and 2 hydrogen atoms $(= 2 \text{ protons } + 2 \text{ electrons}).$

SOLUTION The mass of a neutral ⁴He atom, from Appendix B, is 4.002603 u. The mass of two neutrons and two H atoms (2 protons including the 2 electrons) is

$$
2m_n = 2(1.008665 \text{ u}) = 2.017330 \text{ u}
$$

$$
2m({}^{1}_{1}\text{H}) = 2(1.007825 \text{ u}) = 2.015650 \text{ u}
$$

$$
\text{sum} = 4.032980 \text{ u}.
$$

PROBLEM SOLVING

Keep track of electron masses
Thus the mass of ${}_{2}^{4}$ He is measured to be 4.032980 u - 4.002603 u = 0.030377 u less than the masses of its constituents. Where has this lost mass gone?

It has, in fact, gone into energy of another kind (such as radiation, or kinetic energy, for example). The mass (or energy) difference in the case of ⁴He, given in energy units, is $(0.030377 \text{ u})(931.5 \text{ MeV/u}) = 28.30 \text{ MeV}$. This difference is referred to as the **total binding energy** of the nucleus. The total binding energy represents the amount of energy that must be put into a nucleus in order to break it apart into its constituents. If the mass of, say, a ${}_{2}^{4}He$ nucleus were exactly equal to the mass of two neutrons plus two protons, the nucleus could fall apart without any input of energy. To be stable, the mass of a nucleus *must* be less than that of its constituent nucleons, so that energy input is needed to break it apart. Note that the binding energy is not something a nucleus has—it is energy it "lacks" relative to the total mass of its separate constituents.

[We saw in Chapter 27 that the binding energy of the one electron in the hydrogen atom is 13.6 eV; so the mass of a ${}^{1}_{1}H$ atom is less than that of a single proton plus a single electron by 13.6 eV/ c^2 . Compared to the total mass of the atom (939 MeV/ c^2), this is incredibly small, 1 part in 10⁸. Also, the binding energies of nuclei are on the order of MeV, so the eV binding energies of electrons can be ignored.]

EXERCISE A Determine how much less the mass of the $\frac{7}{3}$ Li nucleus is compared to that of its constituents.

The binding energy per nucleon is defined as the total binding energy of a nucleus divided by A , the total number of nucleons. We calculated above that the binding energy of ⁴₂He is 28.3 MeV, so its binding energy per nucleon is $28.3 \text{ MeV}/4 = 7.1 \text{ MeV}$. Figure 30-1 shows the binding energy per nucleon as a function of A for stable nuclei. The curve rises as A increases and reaches a plateau at about 8.7 MeV per nucleon above $A \approx 40$. Beyond $A \approx 80$, the curve decreases slowly, indicating that larger nuclei are held together a little less tightly than those in the middle of the periodic table. We will see later that these characteristics allow the release of nuclear energy in the processes of fission and fusion.

Binding energy

Binding energy per nucleon

EXAMPLE 30-4 Binding energy for iron. Calculate the total binding energy and the binding energy per nucleon for ${}^{56}_{26}Fe$, the most common stable isotope of iron.

APPROACH We subtract the mass of a ${}^{56}_{26}Fe$ atom from the total mass of 26 hydrogen atoms and 30 neutrons, all found in Appendix B. Then we convert mass units to energy units; finally we divide by $A = 56$, the total number of nucleons. **SOLUTION** ${}^{56}_{26}Fe$ has 26 protons and 30 neutrons whose separate masses are

 $26m({}^{1}_{1}\text{H}) = (26)(1.007825 \text{ u}) = 26.20345 \text{ u}$ (includes 26 electrons) $30m_n = (30)(1.008665 \text{ u}) = 30.25995 \text{ u}$ sum = 56.46340 u. Subtract mass of $^{56}_{26}Fe$: = -55.93494 u (Appendix B) $\Delta m = 0.52846 \text{ u}.$

The total binding energy is thus

 (0.52846 u) $(931.5 \text{ MeV/u}) = 492.26 \text{ MeV}$

and the binding energy per nucleon is

 $\frac{492.26 \text{ MeV}}{56 \text{ nucleons}} = 8.79 \text{ MeV}.$

NOTE The binding energy per nucleon graph (Fig. $30-1$) peaks just about here, for iron, so the iron nucleus (and its neighbors) is the most stable of nuclei.

EXERCISE B Determine the binding energy per nucleon for ${}^{16}_{8}O$.

EXAMPLE 30-5 Binding energy of last neutron. What is the binding energy of the last neutron in $^{13}_{6}$ C?

APPROACH We subtract the mass of $^{13}_{6}C$ from the masses of the atom with one less neutron, ${}^{12}_{6}C$, and a free neutron.

SOLUTION Obtaining the masses from Appendix B, we have

Mass $^{12}_{6}C = 12.000000 \text{ u}$ Mass $\frac{1}{0}n = 1.008665$ u Total = 13.008665 u. Subtract mass of $^{13}_{6}$ C: -13.003355 u $\Delta m = 0.005310 \,\text{u}$

which in energy is $(931.5 \,\text{MeV}/\text{u})(0.005310 \,\text{u}) = 4.95 \,\text{MeV}$. That is, it would require 4.95 MeV input of energy to remove one neutron from $^{13}_{6}C$.

Nuclear Forces

We can analyze nuclei not only from the point of view of energy, but also from the point of view of the forces that hold them together. We would not expect a collection of protons and neutrons to come together spontaneously, since protons are all positively charged and thus exert repulsive electric forces on each other. Indeed, the question arises as to how a nucleus stays together at all in view of the fact that the electric force between protons would tend to break it apart. Since stable nuclei *do* stay together, it is clear that another force must be acting. Because this new force is stronger than the electric force (which, in turn, is much stronger than gravity at the nuclear level), it is called the **strong nuclear force**. The strong nuclear force is an attractive force that acts between all nucleons—protons and neutrons alike. Thus protons attract each other via the strong nuclear force at the same time they repel each other via the electric force. Neutrons, since they are electrically neutral, only attract other neutrons or protons via the strong nuclear force.

The strong nuclear force turns out to be far more complicated than the gravitational and electromagnetic forces. One important aspect of the strong nuclear force is that it is a short-range force: it acts only over a very short distance. It is very strong between two nucleons if they are less than about 10^{-15} m apart, but it is essentially zero if they are separated by a distance greater than this. Compare this to electric and gravitational forces, which decrease as $1/r^2$ but continue acting over any distances and are therefore called **long-range** forces.

The strong nuclear force has some strange quirks. For example, if a nuclide contains too many or too few neutrons relative to the number of protons, the binding of the nucleons is reduced; nuclides that are too unbalanced in this regard are unstable. As shown in Fig. 30-2, stable nuclei tend to have the same number of protons as neutrons $(N = Z)$ up to about $A = 30$ or 40. Beyond this, stable nuclei contain more neutrons than protons. This makes sense since, as Z increases, the electrical repulsion increases, so a greater number of neutronswhich exert only the attractive nuclear force—are required to maintain stability. For very large Z, no number of neutrons can overcome the greatly increased electric repulsion. Indeed, there are no completely stable nuclides above $Z = 82$.

What we mean by a *stable nucleus* is one that stays together indefinitely. What then is an *unstable nucleus*? It is one that comes apart; and this results in radioactive decay. Before we discuss the important subject of radioactivity (next Section), we note that there is a second type of nuclear force that is much weaker than the strong nuclear force. It is called the **weak nuclear force**, and we are aware of its existence only because it shows itself in certain types of radioactive decay. These two nuclear forces, the strong and the weak, together with the gravitational and electromagnetic forces, comprise the four known types of force in nature.

Long- and short-range forces

FIGURE 30-2 Number of neutrons versus number of protons for stable nuclides, which are represented by dots. The straight line represents $N = Z$.

Weak force

30-3 Radioactivity

Nuclear physics had its beginnings in 1896. In that year, Henri Becquerel $(1852-1908)$ made an important discovery; in his studies of phosphorescence, he found that a certain mineral (which happened to contain uranium) would darken a photographic plate even when the plate was wrapped to exclude light. It was clear that the mineral emitted some new kind of radiation that, unlike X-rays, occurred without any external stimulus. This new phenomenon eventually came to be called radioactivity.

Soon after Becquerel's discovery, Marie Curie (1867–1934) and her husband, Pierre Curie (1859–1906), isolated two previously unknown elements that were very highly radioactive (Fig. 30-3). These were named polonium and radium.

Discovery of radioactivity

FIGURE 30-3 Marie and Pierre Curie in their laboratory (about 1906) where radium was discovered.

sample (radium)

FIGURE 30-4 Alpha and beta rays are bent in opposite directions by a magnetic field, whereas gamma rays are not bent at all.

FIGURE 30-5 Radioactive decay of radium to radon with emission of an alpha particle.

 α decay

Daughter nucleus Parent nucleus **Transmutation** Other radioactive elements were soon discovered as well. The radioactivity was found in every case to be unaffected by the strongest physical and chemical treatments, including strong heating or cooling and the action of strong chemical reagents. It was clear that the source of radioactivity must be deep within the atom, that it must emanate from the nucleus. And it became apparent that radioactivity is the result of the *disintegration* or *decay* of an unstable nucleus. Certain isotopes are not stable, and they decay with the emission of some type of radiation or "rays."

Many unstable isotopes occur in nature, and such radioactivity is called "natural radioactivity." Other unstable isotopes can be produced in the laboratory by nuclear reactions (Section $31-1$); these are said to be produced "artificially" and to have "artificial radioactivity."

Rutherford and others began studying the nature of the rays emitted in radioactivity about 1898. They found that the rays could be classified into three distinct types according to their penetrating power. One type of radiation could barely penetrate a piece of paper. The second type could pass through as much as 3 mm of aluminum. The third was extremely penetrating: it could pass through several centimeters of lead and still be detected on the other side. They named these three types of radiation alpha (α) , beta (β), and gamma (γ), respectively, after the first three letters of the Greek alphabet.

Each type of ray was found to have a different charge and hence is bent differently in a magnetic field, Fig. 30–4; α rays are positively charged, β rays are negatively charged, and γ rays are neutral. It was soon found that all three types of radiation consisted of familiar kinds of particles. Gamma rays are very high-energy photons whose energy is even higher than that of X-rays. Beta rays are electrons, identical to those that orbit the nucleus, but they are created within the nucleus itself. Alpha rays (or α particles) are simply the nuclei of helium atoms, ${}_{2}^{4}He$; that is, an α ray consists of two protons and two neutrons bound together.

We now discuss each of these three types of radioactivity, or decay, in more detail.

30-4 Alpha Decay

When a nucleus emits an α particle (${}_{2}^{4}$ He), it is clear that the remaining nucleus will be different from the original: it has lost two protons and two neutrons. Radium 226 ($^{226}_{88}$ Ra), for example, is an α emitter. It decays to a nucleus with $Z = 88 - 2 = 86$ and $A = 226 - 4 = 222$. The nucleus with $Z = 86$ is radon (Rn)—see Appendix B or the periodic table. Thus the radium decays to radon with the emission of an α particle. This is written

$$
^{226}_{88}Ra \rightarrow ^{222}_{86}Rn + ^{4}_{2}He.
$$

See Fig. 30-5.

It is clear that when α decay occurs, a new element is formed. The **daughter** nucleus ($^{222}_{86}$ Rn in this case) is different from the **parent** nucleus ($^{226}_{88}$ Ra in this case). This changing of one element into another is called **transmutation**.

Alpha decay can be written

$$
{}_{Z}^{A}\mathbf{N} \rightarrow {}_{Z-2}^{A-4}\mathbf{N}' + {}_{2}^{4}\mathbf{He}
$$
 [α decay]

where N is the parent, N' the daughter, and Z and A are the atomic number and atomic mass number, respectively, of the parent.

Alpha decay occurs because the strong nuclear force is unable to hold very large nuclei together. Because the nuclear force is a short-range force, it acts only between neighboring nucleons. But the electric force acts all the way across a large nucleus. For very large nuclei, the large Z means the repulsive electric force becomes so large (Coulomb's law) that the strong nuclear force is unable to hold the nucleus together.

Why the strong nuclear force cannot hold a nucleus together

We can express the instability in terms of energy (or mass): the mass of the parent nucleus is greater than the mass of the daughter nucleus plus the mass of the α particle. The mass difference appears as kinetic energy, which is carried away by the α particle and the recoiling daughter nucleus. The total energy released is called the disintegration energy, Q , or the Q -value of the decay. From conservation of energy,

$$
M_{\rm P}c^2 = M_{\rm D}c^2 + m_{\alpha}c^2 + Q,
$$

where $Q = \kappa E$ and M_P , M_D , and m_α are the masses of the parent, daughter, and α particle, respectively. Thus

$$
Q = M_{\rm P}c^2 - (M_{\rm D} + m_a)c^2.
$$
 (30-2) Q-value

If the parent had less mass than the daughter plus the α particle (so $Q < 0$), the decay could not occur spontaneously, for the conservation of energy law would be violated.

EXAMPLE 30-6 Uranium decay energy release. Calculate the disintegration energy when $^{232}_{92}U$ (mass = 232.037146 u) decays to $^{228}_{90}Th$ (228.028731 u) with the emission of an α particle. (As always, masses are for neutral atoms.)

APPROACH We use conservation of energy as expressed in Eq. 30–2. $^{232}_{92}$ U is the parent, $^{228}_{90}$ Th is the daughter.

SOLUTION Since the mass of the ⁴He is 4.002603 u (Appendix B), the total mass in the final state is

 $228.028731 u + 4.002603 u = 232.031334 u.$

The mass lost when the $^{232}_{92}U$ decays is

 $232.037146 \text{ u} - 232.031334 \text{ u} = 0.005812 \text{ u}.$

Since $1 u = 931.5 MeV$, the energy Q released is

$$
Q = (0.005812 \,\text{u})(931.5 \,\text{MeV/u}) \\
\approx 5.4 \,\text{MeV},
$$

and this energy appears as kinetic energy of the α particle and the daughter nucleus.

NOTE Using conservation of momentum, it can be shown that the α particle emitted by a $^{232}_{92}U$ nucleus at rest has a kinetic energy of about 5.3 MeV. Thus, the daughter nucleus—which recoils in the opposite direction from the emitted α particle—has about 0.1 MeV of kinetic energy. See the next Example and/or Problem 65.

Additional Example

EXAMPLE 30-7 KE of the α in ²³²/₉₂U decay. For the ²³²/₉₂U decay of Example 30-6, how much of the 5.4-MeV disintegration energy will be carried off by the α particle?

APPROACH In any reaction, momentum must be conserved as well as energy.

SOLUTION Before disintegation, the nucleus can be assumed to be at rest, so the total momentum was zero. After disintegration, the total vector momentum must still be zero so the magnitude of the α particle's momentum must equal the magnitude of the daughter's momentum (Fig. 30–6):

$$
m_{\alpha}v_{\alpha}=m_{\rm D}v_{\rm D}.
$$

Thus $v_a = m_D v_D / m_a$ and the α 's kinetic energy is

$$
\kappa E_{\alpha} = \frac{1}{2} m_{\alpha} v_{\alpha}^{2} = \frac{1}{2} m_{\alpha} \left(\frac{m_{\rm D} v_{\rm D}}{m_{\alpha}} \right)^{2} = \frac{1}{2} m_{\rm D} v_{\rm D}^{2} \left(\frac{m_{\rm D}}{m_{\alpha}} \right) = \left(\frac{m_{\rm D}}{m_{\alpha}} \right) \kappa E_{\rm D}
$$

$$
= \left(\frac{228.028731 \text{ u}}{4.002603 \text{ u}} \right) \kappa E_{\rm D} = 57 \kappa E_{\rm D}.
$$

The total disintegration energy is $Q = \kappa E_a + \kappa E_D = 57 \kappa E_D + \kappa E_D = 58 \kappa E_D$. Hence

$$
KE_{\alpha} = \frac{57}{58}Q = 5.3 \text{ MeV}.
$$

The lighter α particle carries off (57/58) or 98% of the total KE.

Why α particles?

Why, you may wonder, do nuclei emit this combination of four nucleons called an α particle? Why not just four separate nucleons, or even one? The answer is that the α particle is very strongly bound, so that its mass is significantly less than that of four separate nucleons. As we saw in Example 30–3, two protons and two neutrons separately have a total mass of about 4.032980 u (electrons included). The total mass of $^{228}_{90}$ Th plus four separate nucleons is 232.061711 u, which is greater than the mass of the parent (232.037146) . Such a decay could not occur because it would violate the conservation of energy. Similarly, it is almost always true that the emission of a single nucleon is energetically not possible.

Smoke Detectors—An Application

One widespread application of nuclear physics is present in nearly every home in the form of an ordinary **smoke detector**. The most common type of detector contains about 0.2 mg of the radioactive americium isotope, $^{241}_{95}$ Am, in the form of $AmO₂$. The radiation continually ionizes the nitrogen and oxygen molecules in the air space between two oppositely charged plates. The resulting conductivity allows a small steady current. If smoke enters, the radiation is absorbed by the smoke particles rather than by the air molecules, thus reducing the current. The current drop is detected by the device's electronics and sets off the alarm. The radiation dose that escapes from an intact americium smoke detector is much less than the natural radioactive background, and so can be considered relatively harmless. There is no question that smoke detectors save lives and reduce property damage.

FIGURE 30-6 Momentum conservation in Example 30-7.

 \overline{A} PHYSICS APPLIED

Smoke detector

B^- Decav

Transmutation of elements also occurs when a nucleus decays by β decay—that is, with the emission of an electron or β^- particle. The nucleus $^{14}_{6}$ C, for example, emits an electron when it decays:

$$
^{4}_{6}C \rightarrow ^{14}_{7}N + e^{-} +
$$
 a neutrino,

where e^- is the symbol for the electron. (The symbol ${}_{-1}^{0}e$ is sometimes used for the electron whose charge corresponds to $Z = -1$ and, since it is not a nucleon and has very small mass, then $A = 0$.) The particle known as the neutrino, whose charge $q = 0$ and whose rest mass is very small or zero, was not initially detected and was only later hypothesized to exist, as we shall discuss later in this Section. No nucleons are lost when an electron is emitted, and the total number of nucleons, A , is the same in the daughter nucleus as in the parent. But because an electron has been emitted from the nucleus itself, the charge on the daughter nucleus is $+1e$ greater than that on the parent. The parent nucleus in the decay written above had $Z = +6$, so from charge conservation the nucleus remaining behind must have a charge of $+7e$. So the daughter nucleus has $Z = 7$, which is nitrogen.

It must be carefully noted that the electron emitted in β decay is *not* an orbital electron. Instead, the electron is created *within the nucleus itself*. What happens is that one of the neutrons changes to a proton and in the process (to conserve charge) emits an electron. Indeed, free neutrons actually do decay in this fashion:

 $n \rightarrow p + e^- + a$ neutrino.

Because of their origin in the nucleus, the electrons emitted in β decay are often referred to as " β particles," rather than as electrons, to remind us of their origin. They are, nonetheless, indistinguishable from orbital electrons.

EXAMPLE 30-8 Energy release in $^{14}_{6}$ C decay. How much energy is released when ¹⁴₆C decays to ¹⁴₇N by β emission?

APPROACH We find the mass difference before and after decay, Δm . The energy released is $E = (\Delta m)c^2$. The masses given in Appendix B are those of the neutral atom, and we have to keep track of the electrons involved. Assume the parent nucleus has six orbiting electrons so it is neutral; its mass is 14.003242 u. The daughter in this decay, $^{14}_{7}N$, is not neutral since it has the same six orbital electrons circling it but the nucleus has a charge of $+7e$. However, the mass of this daughter with its six electrons, plus the mass of the emitted electron (which makes a total of seven electrons), is just the mass of a neutral nitrogen atom.

SOLUTION The total mass in the final state is

(mass of $^{14}_{7}N$ nucleus + 6 electrons) + (mass of 1 electron),

and this is equal to

mass of neutral $^{14}_{7}N$ (includes 7 electrons),

which, from Appendix B is a mass of 14.003074 u. So the mass difference is 14.003242 $u - 14.003074 u = 0.000168 u$, which is equivalent to an energy change $\Delta m c^2 = (0.000168 \text{ u})(931.5 \text{ MeV/u}) = 0.156 \text{ MeV}$ or 156 keV. **NOTE** The neutrino doesn't contribute to either the mass or charge balance since it has $q = 0$ and $m \approx 0$.

CAUTION

 β -decay e^- comes from nucleus (not an orbital electron)

FIGURE 30-7 Enrico Fermi. Fermi contributed significantly to both theoretical and experimental physics, a feat almost unique in modern times.

According to Example 30–8, we would expect the emitted electron to have a kinetic energy of 156 keV. (The daughter nucleus, because its mass is very much larger than that of the electron, recoils with very low velocity and hence gets very little of the kinetic energy.) Indeed, very careful measurements indicate that a few emitted β particles do have kinetic energy close to this calculated value. But the vast majority of emitted electrons have somewhat less energy. In fact, the energy of the emitted electron can be anywhere from zero up to the maximum value as calculated above. This range of electron kinetic energy was found for any β decay. It was as if the law of conservation of energy was being violated, and indeed Bohr actually considered this possibility. Careful experiments indicated that linear momentum and angular momentum also did not seem to be conserved. Physicists were troubled at the prospect of having to give up these laws, which had worked so well in all previous situations. In 1930, Wolfgang Pauli proposed an alternate solution: perhaps a new particle that was very difficult to detect was emitted during β decay in addition to the electron. This hypothesized particle could be carrying off the energy, momentum, and angular momentum required to maintain the conservation laws. This new particle was named the **neutrino**—meaning "little neutral one"—by the great Italian physicist Enrico Fermi (1901–1954; Fig. $30-7$), who in 1934 worked out a detailed theory of β decay. (It was Fermi who, in this theory, postulated the existence of the fourth force in nature which we call the *weak nuclear force*.) The electron neutrino has zero charge, spin of $\frac{1}{2}\hbar$, and was long thought to have zero rest mass, although today it seems possible it does have a very tiny rest mass ($\langle 0.6 \text{ eV}/c^2$). If its rest mass is zero, it is much like a photon in that it is neutral and travels at the speed of light. But the neutrino is far more difficult to detect. In 1956, complex experiments produced further evidence for the existence of the neutrino; but by then, most physicists had already accepted its existence.

The symbol for the neutrino is the Greek letter nu (v) . The correct way of writing the decay of $^{14}_{6}C$ is then

 β^- decay

$$
{}^{14}_{6}C \rightarrow {}^{14}_{7}N + e^{-} + \bar{\nu}.
$$

The bar $(\bar{\ })$ over the neutrino symbol is to indicate that it is an "antineutrino." (Why this is called an antineutrino rather than simply a neutrino need not concern us now; it is discussed in Chapter 32.)

B^+ Decay

Many isotopes decay by electron emission. They are always isotopes that have too many neutrons compared to the number of protons. That is, they are isotopes that lie above the stable isotopes plotted in Fig. 30–2. But what about unstable isotopes that have too few neutrons compared to their number of protons—those that fall below the stable isotopes of Fig. 30–2? These, it turns out, decay by emitting a **positron** instead of an electron. A positron (sometimes called an e^+ or β^+ particle) has the same mass as the electron, but it has a positive charge of $+1e$. Because it is so like an electron, except for its charge, the positron is called the **antiparticle**^{\dagger} to the electron. An example of a β^+ decay is that of $^{19}_{10}Ne$:

Positron (β^+) decay

$$
^{19}_{10}
$$
Ne \rightarrow $^{19}_{9}$ F + e⁺ + ν .

where e^+ (or ${}^{0}_{1}e$) stands for a positron. Note that the ν emitted here is a neutrino, whereas that emitted in β^- decay is called an antineutrino. Thus an antielectron $(=$ positron) is emitted with a neutrino, whereas an antineutrino is emitted with an electron; this gives a certain balance as discussed in Chapter 32.

[†]Discussed in Chapter 32. Briefly, an antiparticle has the same mass as its corresponding particle, but opposite charge.

We can write β^- and β^+ decay, in general, as follows:

$$
{}_{Z}^{A}\mathbf{N} \rightarrow {}_{Z+1}^{A}\mathbf{N}' + \mathbf{e}^{-} + \overline{\nu}
$$

\n
$$
{}_{Z}^{A}\mathbf{N} \rightarrow {}_{Z-1}^{A}\mathbf{N}' + \mathbf{e}^{+} + \nu,
$$

\n
$$
{}_{Z}^{A}\mathbf{N} \rightarrow {}_{Z-1}^{A}\mathbf{N}' + \mathbf{e}^{+} + \nu,
$$

\n
$$
{}_{Z}^{A}\mathbf{N} \rightarrow {}_{Z}^{A}\mathbf{N}' + \mathbf{e}^{+} + \nu,
$$

\n
$$
{}_{Z}^{A}\mathbf{N} \rightarrow {}_{Z}^{A}\mathbf{N}' + \mathbf{e}^{+} + \nu,
$$

\n
$$
{}_{Z}^{A}\mathbf{N} \rightarrow {}_{Z}^{A}\mathbf{N}' + \mathbf{e}^{+} + \nu,
$$

where N is the parent nucleus and N' is the daughter.

Electron Capture

Besides β^- and β^+ emission, there is a third related process. This is electron capture (abbreviated EC in Appendix B) and occurs when a nucleus absorbs one of its orbiting electrons. An example is ${}_{4}^{7}Be$, which as a result becomes ${}_{3}^{7}Li$. The process is written

$$
{}_{4}^{7}\text{Be} + e^{-} \rightarrow {}_{3}^{7}\text{Li} + \nu,
$$

or, in general,

$$
{}_{Z}^{A}N + e^{-} \rightarrow {}_{Z-1}^{A}N' + \nu.
$$
 [electron capture]

Usually it is an electron in the innermost (K) shell that is captured, in which case it is called "K-capture." The electron disappears in the process, and a proton in the nucleus becomes a neutron; a neutrino is emitted as a result. This process is inferred experimentally by detection of emitted X-rays (due to other electrons jumping down to fill the empty state) of just the proper energy.

In β decay, it is the weak nuclear force that plays the crucial role. The neutrino is unique in that it interacts with matter only via the weak force, which is why it is so hard to detect.

Gamma Decay

Gamma rays are photons having very high energy. They have their origin in the decay of a nucleus, much like emission of photons by excited atoms. Like an atom, a nucleus itself can be in an excited state. When it jumps down to a lower energy state, or to the ground state, it emits a photon which we call a γ ray. The possible energy levels of a nucleus are much farther apart than those of an atom: on the order of keV or MeV, as compared to a few eV for electrons in an atom. Hence, the emitted photons have energies that can range from a few keV to several MeV. For a given decay, the γ ray always has the same energy. Since a γ ray carries no charge, there is no change in the element as a result of a γ decay.

How does a nucleus get into an excited state? It may occur because of a violent collision with another particle. More commonly, the nucleus remaining after a previous radioactive decay may be in an excited state. A typical example is shown in the energy-level diagram of Fig. $30-8$. $^{12}_{5}B$ can decay by β decay directly to the ground state of ${}^{12}_{6}C$; or it can go by β decay to an excited state of ${}^{12}_{6}C$, which then decays by emission of a 4.4-MeV γ ray to the ground state.

We can write γ decay as

$$
{}_{Z}^{A}\mathbf{N}^{*} \rightarrow {}_{Z}^{A}\mathbf{N} + \gamma, \qquad \qquad [\gamma
$$

where the asterisk means "excited state" of that nucleus.

* Isomers; Internal Conversion

In some cases, a nucleus may remain in an excited state for some time before it emits a γ ray. The nucleus is then said to be in a **metastable state** and is called an isomer.

An excited nucleus can sometimes return to the ground state by another process known as **internal conversion** with no γ ray emitted. In this process, the excited nucleus interacts with one of the orbital electrons and ejects this electron from the atom with the same kinetic energy (minus the binding energy of the electron) that an emitted γ ray would have had.

Electron capture

K-capture

FIGURE 30-8 Energy-level diagram showing how $^{12}_{5}B$ can decay to the ground state of ${}^{12}_{6}C$ by β decay (total energy released = 13.4 MeV), or can instead β decay to an excited state of ${}^{12}_{6}C$ (indicated by *), which subsequently decays to its ground state by emitting a 4.4-MeV γ ray.

Internal conversion

decay]

What, you may wonder, is the difference between a γ ray and an X-ray? They both are electromagnetic radiation (photons) and, though γ rays usually have higher energy than X-rays, their range of energies overlap to some extent. The difference is not intrinsic. We use the term X-ray if the photon is produced by an electron-atom interaction, and γ ray if the photon is produced in a nuclear process.

TABLE 30-2 The Three **Types of Radioactive Decay**

 α decay: $\frac{A}{2}N \rightarrow \frac{A-4}{2}N' + \frac{4}{2}He$ B decay: $^A_ZN \rightarrow ^A_{Z+1}N' + e^- + \overline{\nu}$ $\hat{\mathcal{D}}N \rightarrow \hat{\mathcal{D}}_{-1}N' + e^+ + \nu$ $\frac{A}{2}N + e^- \rightarrow \frac{A}{2-1}N' + \nu$ [EC][†] γ decay: $\hat{\beta}N^* \rightarrow \hat{\beta}N + \gamma$

[†] Electron capture.

*Indicates the excited state of a nucleus.

30-7 Conservation of Nucleon Number and **Other Conservation Laws**

In all three types of radioactive decay, the classical conservation laws hold. Energy, linear momentum, angular momentum, and electric charge are all conserved. These quantities are the same before the decay as after. But a new conservation law is also revealed, the law of conservation of nucleon number. According to this law, the total number of nucleons (A) remains constant in any process, although one type can change into the other type (protons into neutrons or vice versa). This law holds in all three types of decay. Table 30–2 gives a summary of α , β , and γ decay.

30-8 Half-Life and Rate of Decay

A macroscopic sample of any radioactive isotope consists of a vast number of radioactive nuclei. These nuclei do not all decay at one time. Rather, they decay one by one over a period of time. This is a random process: we can not predict exactly when a given nucleus will decay. But we can determine, on a probabilistic basis, approximately how many nuclei in a sample will decay over a given time period, by assuming that each nucleus has the same probability of decaying in each second that it exists.

The number of decays ΔN that occur in a very short time interval Δt is then proportional to Δt and to the total number N of radioactive nuclei present:

$$
\Delta N = -\lambda N \Delta t \tag{30-3a}
$$

where the minus sign means N is decreasing. We rewrite this to get the rate of decay, and drop the minus sign

$$
\frac{\Delta N}{\Delta t} = \lambda N. \tag{30-3b}
$$

In these equations, λ is a constant of proportionality called the **decay constant**, which is different for different isotopes. The greater λ is, the greater the rate of decay $(\Delta N/\Delta t)$ and the more "radioactive" that isotope is said to be. The number of decays that occur in the short time interval Δt is designated ΔN because each decay that occurs corresponds to a decrease by one in the number N of nuclei present. That is, radioactive decay is a "one-shot" process, Fig. 30–9. Once a particular parent nucleus decays into its daughter, it cannot do it again.

Exponential Decay

Equation 30–3a or b can be solved for N (using calculus) and the result is

$$
N = N_0 e^{-\lambda t}, \tag{30-4} \quad Radioa
$$

ctive decay law

where N_0 is the number of nuclei present at time $t = 0$, and N is the number remaining after a time t . The symbol e is the natural exponential (encountered earlier in Sections 19-6 and 21-11) whose value is $e = 2.718...$ Thus the number of parent nuclei in a sample decreases exponentially in time, as shown in Fig. 30–10a for $^{14}_{6}$ C decay. Equation 30–4 is called the radioactive decay law.

FIGURE 30–10 (a) The number N of parent nuclei in a given sample of $^{14}_{6}$ C decreases exponentially. (b) The number of decays per second also decreases exponentially. The half-life of $^{14}_{6}$ C is 5730 yr, which means that the number of parent nuclei, N, and the rate of decay, $\Delta N/\Delta t$, decreases by half every 5730 yr.

The number of decays per second, $\Delta N/\Delta t$, is called the **activity** (or rate of decay) of the sample. Since $\Delta N/\Delta t$ is proportional to N (see Eq. 30–3b), it, too, decreases exponentially in time at the same rate (Fig. $30-10b$). The activity at time t is given by

$$
\frac{\Delta N}{\Delta t} = \left(\frac{\Delta N}{\Delta t}\right)_0 e^{-\lambda t},\tag{30-5} \tag{30-5}
$$
 Activity

where $(\Delta N/\Delta t)_{0}$ is the activity at $t = 0$.

Half-Life

The rate of decay of any isotope is often specified by giving its "half-life" rather than the decay constant λ . The **half-life** of an isotope is defined as the time it takes for half the original amount of parent isotope in a given sample to decay. For example, the half-life of $^{14}_{6}C$ is about 5730 years. If at some time a piece of petrified wood contains, say, 1.00×10^{22} nuclei of $^{14}_{6}$ C, then 5730 years later it will contain only 0.50×10^{22} of these nuclei. After another 5730 years it will contain 0.25×10^{22} nuclei, and so on. This is shown in Fig. 30–10a. Since the rate of decay $\Delta N/\Delta t$ is proportional to N, it, too, decreases by a factor of 2 every half-life (Fig. 30-10b).

The half-lives of known radioactive isotopes vary from as short as 10^{-22} s to about 10^{28} s (about 10^{21} yr). The half-lives of many isotopes are given in Appendix B. It should be clear that the half-life (which we designate T_1) bears an inverse relationship to the decay constant. The longer the half-life of an isotope, the more slowly it decays, and hence λ is smaller. Conversely, very active isotopes (large λ) have very short half-lives. The precise relationship between half-life and decay constant is

$$
T_{\frac{1}{2}}=\frac{\ln 2}{\lambda}=\frac{0.693}{\lambda}.
$$

We derive this in the next (optional) subsection.

 $(30-6)$ Half-life

* Deriving the Half-Life Formula; Mean Life

We can derive Eq. 30–6 starting from Eq. 30–4 by setting $N = N_0/2$ at $t = T_{\frac{1}{2}}$.

$$
\frac{N_0}{2}=N_0e^{-\lambda T_{\frac{1}{2}}}
$$

SO.

 $e^{\lambda T_{\frac{1}{2}}} = 2.$

We take natural logs of both sides ("ln" and " e " are inverse operations, meaning $\ln(e^x) = x$ and find

 $\ln(e^{\lambda T_{\frac{1}{2}}}) = \ln 2$,

SO

$$
\lambda T_{\frac{1}{2}} = \ln 2 = 0.693
$$

and

$$
T_{\frac{1}{2}}=\frac{\ln 2}{\lambda}=\frac{0.693}{\lambda},
$$

which is Eq. $30-6$.

You may find the *mean life* of an isotope quoted. The mean life τ is defined as $\tau = 1/\lambda$, so that Eq. 30–4 can written $N = N_0 e^{-t/\tau}$ just as for RC and LR circuits (Chapters 19 and 21) where τ is called the time constant. Then (see also Eq. 30–6)

$$
\tau = \frac{1}{\lambda} = \frac{T_{\frac{1}{2}}}{0.693};
$$

the mean life and half-life differ significantly in numerical value, so confusing them can cause serious error (and has).

Calculations Involving Decay Rates 30–9 and Half-Life

Let us now consider Examples of what we can determine about a sample of radioactive material if we know the half-life.

EXAMPLE 30-9 Sample activity. The isotope $^{14}_{6}$ C has a half-life of 5730 yr. If at some time a sample contains 1.00×10^{22} carbon-14 nuclei, what is the activity of the sample?

APPROACH We first use the half-life to find the decay constant (Eq. 30–6), and use that to find the activity, Eq. 30–3b. The number of seconds in a year is $(60)(60)(24)(365\frac{1}{4}) = 3.156 \times 10^7$ s.

SOLUTION The decay constant λ from Eq. 30–6 is

$$
\lambda = \frac{0.693}{T_{\frac{1}{2}}} = \frac{0.693}{(5730 \text{ yr})(3.156 \times 10^7 \text{ s/yr})} = 3.83 \times 10^{-12} \text{ s}^{-1}.
$$

From Eq. 30–3b, the magnitude of the activity or rate of decay is

$$
\frac{\Delta N}{\Delta t} = \lambda N = (3.83 \times 10^{-12} \,\text{s}^{-1})(1.00 \times 10^{22})
$$

$$
= 3.83 \times 10^{10} \,\text{decays/s}.
$$

Notice that the graph of Fig. 30–10b starts at this value, corresponding to the original value of $N = 1.0 \times 10^{22}$ nuclei in Fig. 30–10a.

NOTE The unit "decays/s" is often written simply as s^{-1} since "decays" is not a unit but refers only to the number. This simple unit of activity is called the becquerel: $1 \text{Bq} = 1 \text{ decay/s}$, as discussed in Chapter 31.

EXERCISE C Determine the decay constant for radium $(T\frac{1}{2} = 1600 \text{ yr})$.

CONCEPTUAL EXAMPLE 30-10 Safety: activity versus half-life. One might think that a short half-life material is safer than a long half-life material because it will not last as long. Is this an accurate representation of the situation?

RESPONSE No. A shorter half-life means the activity is higher and thus more "radioactive" and dangerous. On the other hand, a shorter half-life means the material will all decay to a low level sooner. For the same sample size N, a short half-life material is more radioactive but for a shorter time.

EXERCISE D The isotope ${}^{60}_{27}$ Co, used for radiation treatments in hospitals, has a half-life of about 5.3 years. If a hospital buys a $^{60}_{27}$ Co sample, will it all be gone in 10.6 years (two half-lives)?

Additional Example

EXAMPLE 30-11 A sample of radioactive ¹³₇N. A laboratory has 1.49 μ g of pure $^{13}_{7}N$, which has a half-life of 10.0 min (600 s). (a) How many nuclei are present initially? (b) What is the activity initially? (c) What is the activity after 1.00 h? (d) After approximately how long will the activity drop to less than one per second $(1 s^{-1})?$

APPROACH We use the definition of the mole and Avogadro's number (Sections 13–7 and 13–9) to find the number of nuclei. For (b) we get λ from the given half-life and use Eq. 30–3b for the activity. For (c) and (d) we use Eq. 30–5, and/or make a Table of the times.

SOLUTION (a) The atomic mass is 13.0, so 13.0 g will contain 6.02 \times 10²³ nuclei (Avogadro's number). Since we have only 1.49 \times 10⁻⁶ g, the number of nuclei N₀ that we have initially is given by the ratio

$$
\frac{N_0}{6.02 \times 10^{23}} = \frac{1.49 \times 10^{-6} \text{ g}}{13.0 \text{ g}}
$$

so $N_0 = 6.90 \times 10^{16}$ nuclei.

(b) From Eq. 30–6, $\lambda = (0.693)/(600 s) = 1.16 \times 10^{-3} s^{-1}$. Then, at $t = 0$ $(Eq. 30-3b),$

$$
\left(\frac{\Delta N}{\Delta t}\right)_0 = \lambda N_0 = (1.16 \times 10^{-3} \,\mathrm{s}^{-1})(6.90 \times 10^{16}) = 8.00 \times 10^{13} \,\mathrm{decays/s}.
$$

 (c) The half-life is 10.0 min, so the decay rate decreases by half every 10.0 min. We can make the Table of activity (in the margin) after given periods of time. After 1.0 h, the activity is 1.25×10^{12} decays/s.

Easy Alternate Solution (c) 60 minutes is 6 half-lives, so the activity will decrease to $(\frac{1}{2})(\frac{1}{2})(\frac{1}{2})(\frac{1}{2})(\frac{1}{2}) = (\frac{1}{2})^6 = \frac{1}{64}$ of its original value, or $(8.00 \times 10^{13})/(64) = 1.25 \times 10^{12}$ per second.

General Alternate Solution (c) The general way to find the activity, which works even when the time is not a perfect multiple of $T_{\frac{1}{2}}$, is to use Eq. 30–5. We set $t = 60.0$ min = 3600 s:

$$
\frac{\Delta N}{\Delta t} = \left(\frac{\Delta N}{\Delta t}\right)_0 e^{-\lambda t} = (8.00 \times 10^{13} \,\mathrm{s}^{-1}) e^{-(1.16 \times 10^{-3} \,\mathrm{s}^{-1})(3600 \,\mathrm{s})} = 1.23 \times 10^{12} \,\mathrm{s}^{-1}.
$$

NOTE The slight discrepancy in results arises because we kept only three sign figures.

(d) We want to determine the time t when $\Delta N/\Delta t = 1.00 s^{-1}$. From Eq. we have

$$
e^{-\lambda t} = \frac{(\Delta N/\Delta t)}{(\Delta N/\Delta t)_0} = \frac{1.00 \text{ s}^{-1}}{8.00 \times 10^{13} \text{ s}^{-1}} = 1.25 \times 10^{-14}.
$$

We take the natural log (ln) of both sides (remember $\ln e^{-\lambda t} = -\lambda t$) and divide by λ to find

$$
t = -\frac{\ln(1.25 \times 10^{-14})}{\lambda} = 2.76 \times 10^4 \text{ s} = 7.67 \text{ h}.

30-10 Decay Series

It is often the case that one radioactive isotope decays to another isotope that is also radioactive. Sometimes this daughter decays to yet a third isotope which also is radioactive. Such successive decays are said to form a **decay series**. An important example is illustrated in Fig. 30–11. As can be seen, $^{238}_{92}$ U decays by α emission to $^{234}_{90}$ Th, which in turn decays by β decay to $^{234}_{91}$ Pa. The series continues as shown, with several possible branches near the bottom, ending at the stable lead isotope, $^{206}_{82}Pb$. The two last decays can be

$$
^{206}_{81}\text{T1} \rightarrow ^{206}_{82}\text{Pb} + e^- + \bar{\nu}
$$

or

$$
{}^{210}_{84}\text{Po} \rightarrow {}^{206}_{82}\text{Pb} + \alpha.
$$

Other radioactive series also exist.

FIGURE 30-11 Decay series beginning with $^{238}_{92}$ U. Nuclei in the series are specified by a dot representing A and Z values. Half-lives are given in seconds (s), minutes (min), hours (h), days (d), or years (yr). Note that a horizontal arrow represents β decay (A does not change), whereas a diagonal line represents α decay (A changes by 4, Z changes by 2).

of $^{226}_{88}$ Ra is continually replenished, which is why it is still found on Earth today. The same can be said for many other radioactive nuclides.

CONCEPTUAL EXAMPLE 30-12 Decay chain. The decay chain starting with $^{234}_{92}U$ in Fig. 30–11 has four successive nuclides with half-lives of 250,000 yr, 75,000 yr, 1600 yr, and a little under 4 days. Each decay in the chain has an alpha particle of a characteristic energy, and so we can monitor the radioactive decay rate of each nuclide. Given a sample that was pure $^{234}_{92}U$ a million years ago, which alpha decay would you expect to have the highest activity rate in the sample?

RESPONSE The first instinct is to say that the process with the shortest halflife would show the highest activity. Surprisingly, however, the activity rates in this sample are all the same! The reason is that in each case the decay of the parent acts as a bottleneck to the decay of the daughter. Compared to the 1600-yr half-life of $^{226}_{88}$ Ra, for example, its daughter $^{222}_{86}$ Rn decays almost immediately, but it cannot decay until it is made. (This is like an automobile assembly line: if worker A takes 20 minutes to do a task and then worker B takes only 1 minute to do the next task, worker B still does only one car every 20 minutes).

30-11 Radioactive Dating

Radioactive decay has many interesting applications. One is the technique of radioactive dating by which the age of ancient materials can be determined.

The age of any object made from once-living matter, such as wood, can be determined using the natural radioactivity of $^{14}_{6}$ C. All living plants absorb carbon dioxide $(CO₂)$ from the air and use it to synthesize organic molecules. The vast majority of these carbon atoms are $^{12}_{6}C$, but a small fraction, about 1.3×10^{-12} , is the radioactive isotope ¹⁴₄C. The ratio of ¹⁴₄C to ¹²₄C in the atmosphere has remained roughly constant over many thousands of years, in spite of the fact that ${}^{14}_{6}C$ decays with a half-life of about 5730 yr. This is because energetic nuclei in the cosmic radiation, which impinges on the Earth from outer-space, strike nuclei of atoms in the atmosphere and break those nuclei into pieces, releasing free neutrons. Those neutrons can collide with nitrogen nuclei in the atmosphere to produce the following nuclear transformation: $n + {}^{14}_{7}N \rightarrow {}^{14}_{6}C + p$. That is, a neutron strikes and is absorbed by a ${}^{14}_{7}N$ nucleus, and a proton is knocked out in the process. The remaining nucleus is $^{14}_{6}$ C. This continual production of ${}^{14}_{6}C$ in the atmosphere roughly balances the loss of ${}^{14}_{6}C$ by radioactive decay. As long as a plant or tree is alive, it continually uses the carbon from carbon dioxide in the air to build new tissue and to replace old. Animals eat plants, so they too are continually receiving a fresh supply of carbon for their tissues.

Organisms cannot distinguish^{† 14}₆C from ¹²₆C, and since the ratio of ¹⁴₆C to ¹²₆C in the atmosphere remains nearly constant, the ratio of the two isotopes within the living organism remains nearly constant as well. When an organism dies, carbon dioxide is no longer absorbed and utilized. Because the $^{14}_{6}$ C decays radioactively, the ratio of ${}^{14}_{6}C$ to ${}^{12}_{6}C$ in a dead organism decreases over time. Since the half-life of ${}^{14}_{6}C$ is about 5730 yr, the ${}^{14}_{6}C/{}^{12}_{6}C$ ratio decreases by half every 5730 yr. If, for example, the $^{14}_{6}C/^{12}_{6}C$ ratio of an ancient wooden tool is half of what it is in living trees, then the object must have been made from a tree that was felled about 5730 years ago. Actually, corrections must be made for the fact that the $^{14}_{6}C/^{12}_{6}C$ ratio in the atmosphere has not remained precisely constant over time. The determination of what this ratio has been over the centuries has required techniques such as comparing the expected ratio to the actual ratio for objects whose age is known, such as very old trees whose annual rings can be counted reasonably accurately.

[†]Organisms operate almost exclusively via chemical reactions—which involve only the outer orbital electrons of the atom; extra neutrons in the nucleus have essentially no effect.

 ${}^{14}C$ formation in atmosphere

Additional Example

EXAMPLE 30-13 An ancient animal. The mass of carbon in an animal bone fragment found in an archeological site is 200 g. If the bone registers an activity of 16 decays/s, what is its age?

APPROACH First we determine how many ${}^{14}_{6}C$ atoms there were in our 200-g sample when the animal was alive, given the known fraction of $^{14}_{6}C$, 1.3×10^{-12} . Then we use Eq. 30-3b to find the activity back then, and Eq. 30–5 to find out how long ago that was by solving for the time t .

SOLUTION The 200 g of carbon is nearly all ¹²₆C; 12.0 g of ¹²₆C contains 6.02×10^{23} atoms, so 200 g contains

$$
\left(\frac{6.02 \times 10^{23} \text{ atoms}}{12 \text{ g}}\right) (200 \text{ g}) = 1.00 \times 10^{25} \text{ atoms.}
$$

When the animal was alive, the ratio of $^{14}_{6}$ C to $^{12}_{6}$ C in the bone was 1.3 \times 10⁻¹². The number of $^{14}_{6}$ C nuclei at that time was

 $N_0 = (1.00 \times 10^{25} \text{ atoms})(1.3 \times 10^{-12}) = 1.3 \times 10^{13} \text{ atoms}.$

From Eq. 30-3b the magnitude of the activity when the animal was alive $(t = 0)$ was

$$
\left(\frac{\Delta N}{\Delta t}\right)_0 = \lambda N_0,
$$

where $\lambda = 3.83 \times 10^{-12}$ s⁻¹ as we calculated in Example 30–9. So the original activity was

$$
\left(\frac{\Delta N}{\Delta t}\right)_0 = \lambda N_0 = (3.83 \times 10^{-12} \,\mathrm{s}^{-1})(1.3 \times 10^{13}) = 50 \,\mathrm{s}^{-1}.
$$

From Eq. 30-5

$$
\frac{\Delta N}{\Delta t} = \left(\frac{\Delta N}{\Delta t}\right)_0 e^{-\lambda t}
$$

where $\Delta N/\Delta t$ is given as 16 s⁻¹. Then

$$
16\,\mathrm{s}^{-1} = (50\,\mathrm{s}^{-1})e^{-\lambda t}
$$

or

$$
e^{\lambda t} = \frac{50}{16}
$$

We take natural logs of both sides to obtain

$$
t = \frac{1}{\lambda} \ln \left(\frac{50}{16} \right) = \frac{1}{3.83 \times 10^{-12} \text{ s}^{-1}} \ln \left(\frac{50}{16} \right)
$$

$$
= 2.98 \times 10^{11} \text{ s} = 9400 \text{ yr},
$$

which is the time elapsed since the death of the animal.

Geological Time Scale Dating

Carbon dating is useful only for determining the age of objects less than about 60,000 years old. The amount of $^{14}_{6}$ C remaining in objects older than that is usually too small to measure accurately, although new techniques are allowing detection of even smaller amounts of $^{14}_{6}C$, pushing the time frame further back. On the other hand, radioactive isotopes with longer half-lives can be used in certain circumstances to obtain the age of older objects. For example, the decay of $^{238}_{92}$ U, because of its long half-life of 4.5 \times 10⁹ years, is useful in determining the ages of rocks on a geologic time scale. When molten material on Earth long ago solidified into rock as the temperature dropped, different compounds solidified according to the melting points, and thus different compounds separated to some extent. Uranium present in a material became fixed in position and the daughter nuclei that result from the decay of uranium were also fixed in that position. Thus, by measuring the amount of $^{238}_{92}U$ remaining in the material relative to the amount of daughter nuclei, the time when the rock solidified can be determined.

Radioactive dating methods using $^{238}_{92}U$ and other isotopes have shown the age of the oldest Earth rocks to be about 4×10^9 yr. The age of rocks in which the oldest fossilized organisms are embedded indicates that life appeared more than 3.5 billion years ago. The earliest fossilized remains of mammals are found in rocks 200 million years old, and the first humanlike creatures seem to have appeared about 2 million years ago. Radioactive dating has been indispensable for the reconstruction of Earth's history.

30–12 Stability and Tunneling

We have seen that radioactive decay occurs only when the mass of the parent nucleus is greater than the sum of the masses of the daughter nucleus and all particles emitted. For example, $^{238}_{92}U$ can decay to $^{234}_{90}Th$ because the mass of $^{238}_{92}U$ is greater than the mass of the $^{234}_{90}$ Th plus the mass of the α particle. Since systems tend to go in the direction that reduces their internal or potential energy (a ball rolls downhill, a positive charge moves toward a negative charge). you may wonder why an unstable nucleus doesn't fall apart immediately. In other words, why do ²³⁸₉₂U nuclei ($T_1 = 4.5 \times 10^9$ yr) and other isotopes have such long half-lives? Why don't parent nuclei all decay at once?

The answer has to do with quantum theory and the nature of the forces involved. One way to view the situation is with the aid of a potential-energy diagram, as in Fig. 30-12. Let us consider the particular case of the decay $^{238}_{92}\text{U} \rightarrow ^{234}_{90}\text{Th} + ^{4}_{2}\text{He}$. The blue line represents the potential energy, including rest mass, where we imagine the α particle as a separate entity within the $^{238}_{92}U$ nucleus. The region labeled A in Fig. 30-12 represents the PE of the α particle when it is held within the uranium nucleus by the nuclear force $(R_0$ is the nuclear radius). Region C represents the PE when the α particle is free of the nucleus. The downward-curving PE (proportional to $1/r$) represents the electrical (Coulomb's law) repulsion between the positively charged α and the ²³⁴₉₀Th nucleus. To get to region C, the α particle has to get by the "Coulomb" barrier shown. Since the PE just beyond $r = R_0$ (region B) is greater than the energy of the alpha particle (dashed line), the α particle could not escape the nucleus if it were governed by classical physics. It could escape only if there were an input of energy equal to the height of the barrier. Nuclei decay spontaneously, however, without any input of energy. How, then, does the α particle get from region A to region C? It actually passes through the barrier in a process known as tunneling. Classically, this could not happen, because an α particle in region B (within the barrier) would be violating the conservation-of-energy principle.[†] The uncertainty principle, however, tells us that energy conservation can be violated by an amount ΔE for a length of time Δt given by

$$
(\Delta E)(\Delta t) \approx \frac{h}{2\pi}
$$

We saw in Section 28-3 that this is a result of the wave-particle duality. Thus quantum mechanics allows conservation of energy to be violated for brief periods that may be long enough for an α particle to "tunnel" through the barrier. ΔE would represent the energy difference between the average barrier height and the particle's energy, and Δt the time to pass through the barrier. The higher and wider the barrier, the less time the α particle has to escape and the less likely it is to do so. It is therefore the height and width of this barrier that controls the rate of decay and half-life of an isotope.

[†]The total energy E (dashed line in Fig. 30–12) would be less than the PE; because $KE = \frac{1}{2}mv^2 > 0$, then $E = KE + PE$ could not be less than the PE classically.

30-13 Detection of Radiation

Individual particles such as electrons, protons, α particles, neutrons, and γ rays are not detected directly by our senses. Consequently, a variety of instruments have been developed to detect them.

One of the most common is the Geiger counter. As shown in Fig. 30–13, it consists of a cylindrical metal tube filled with a certain type of gas. A long wire runs down the center and is kept at a high positive voltage ($\approx 10^3$ V) with respect to the outer cylinder. The voltage is just slightly less than that required to ionize the gas atoms. When a charged particle enters through the thin "window" at one end of the tube, it ionizes a few atoms of the gas. The freed electrons are attracted toward the positive wire, and as they are accelerated they strike and ionize additional atoms. An "avalanche" of electrons is quickly produced, and when it reaches the wire anode, it produces a voltage pulse. The pulse, after being amplified, can be sent to an electronic counter, which counts how many particles have been detected. Or the pulses can be sent to a loudspeaker and each detection of a particle is heard as a "click." Only a fraction of the radiation emitted by a sample is detected by any detector.

A scintillation counter makes use of a solid, liquid, or gas known as a scintillator or phosphor. The atoms of a scintillator are easily excited when struck by an incoming particle and emit visible light when they return to their ground states. Typical scintillators are crystals of NaI and certain plastics. One face of a solid scintillator is cemented to a photomultiplier tube, and the whole is wrapped with opaque material to keep it light tight or is placed within a light-tight container. The **photomultiplier** (PM) **tube** converts the energy of the scintillator-emitted photon(s) into an electric signal. A PM tube is a vacuum tube containing several electrodes (typically 8 to 14), called *dynodes*, which are maintained at successively higher voltages as shown in Fig. 30-14. At its top surface is a photoelectric surface, called the *photocathode*, whose work function (Section $27-3$) is low enough that an electron is easily released when struck by a photon from the scintillator. Such an electron is accelerated toward the first dynode. When it strikes the first dynode, the electron has acquired sufficient kinetic energy so that it can eject two to five more electrons. These, in turn, are accelerated to the second dynode, and a multiplication process begins. The number of electrons striking the last dynode may be $10⁶$ or more. Thus the passage of a particle through the scintillator results in an electric signal at the

FIGURE 30-14 Scintillation counter with a photomultiplier tube.

output of the PM tube that can be sent to an electronic counter just as for a Geiger tube. Solid scintillators are much more dense than the gas of a Geiger counter, and so are much more efficient detectors—especially for γ ravs, which interact less with matter than do β ravs. Scintillators that can measure the total energy deposited are much used today and are called calorimeters.

In tracer work (Section $31-7$), liquid scintillators are often used. Radioactive samples taken at different times or from different parts of an organism are placed directly in small bottles containing the liquid scintillator. This is particularly convenient for detection of β rays from ${}_{1}^{3}H$ and ${}_{6}^{14}C$, which have very low energies and have difficulty passing through the outer covering of a crystal scintillator or Geiger tube. A PM tube is still used to produce the electric signal.

A semiconductor detector consists of a reverse-biased pn junction diode (Section 29-8). A particle passing through the junction can excite electrons into the conduction band, leaving holes in the valence band. The freed charges produce a short electrical pulse that can be counted just as for Geiger and scintillation counters. Silicon wafer semiconductors have their surface etched into tiny pixels, thus providing detailed particle position information.

Hospital workers and others who work around radiation carry film badges which detect the accumulation of radiation. The film inside is periodically replaced and developed, the darkness being related to total exposure (see Section 31–5).

The devices discussed so far are used for counting the number of particles (or decays of a radioactive isotope). Other devices allow the track of charged particles to be seen. The simplest is the photographic emulsion, which can be small and portable, used now particularly for cosmic-ray studies from balloons. A charged particle passing through a layer of photographic emulsion ionizes the atoms along its path. These points undergo a chemical change, and when the emulsion is developed the particle's path is revealed. (One type of neutrino, τ , was indirectly discovered using an emulsion at Fermilab; see Chapter 32.)

In a cloud chamber, a gas is cooled to a temperature slightly below its usual condensation point ("supercooled"), and gas molecules condense on any ionized molecules present. Ions produced when a charged particle passes through serve as centers on which tiny droplets form (Fig. 30–15). Light scatters more from these droplets than from the gas background, so a photo of the cloud chamber at the right moment shows the track of the particle. An important instrument in the early days of nuclear physics, it is little used today.

The **bubble chamber**, invented in 1952 by D. A. Glaser (1926–), makes use of a superheated liquid kept close to its normal boiling point. The bubbles characteristic of boiling form around ions produced by the passage of a charged particle. A photograph of the interior of the chamber reveals paths of particles that recently passed through. Because the bubble chamber uses a liquid, often liquid hydrogen, it is a much more efficient device than a cloud chamber for observing the tracks of charged particles and their interactions with the nuclei of the liquid. A magnetic field is usually applied across the chamber and the momentum of the moving particles can be determined from the radius of curvature of their paths.

Calorimeter

Semiconductor detector (pn junction)

Emulsions

Cloud chamber

Bubble chamber

FIGURE 30-15 In a cloud or bubble chamber, droplets or bubbles are formed around ions produced by the passage of a charged particle.

FIGURE 30-16 Wire-drift chamber inside the Collider Detector at Fermilab (CDF). The photo at the start of Chapter 32 (page 889) was done with this detector.

Wire drift chamber

A wire drift chamber consists of a set of closely spaced fine wires immersed in a gas (Fig. 30–16). Many wires are grounded, and the others between are kept at very high voltage. A charged particle passing through produces ions in the gas. Freed electrons drift toward the nearest high voltage wires, creating an "avalanche," and producing an electric pulse or signal at that wire. The positions of the particles are determined electronically by the position of the wire and by the time it takes the pulses to reach "readout" electronics at the ends of the wires. The paths of the particles are reconstructed electronically by computers which can "draw" a picture of the tracks, as shown in the photo at the start of Chapter 32.

Summary

Nuclear physics is the study of atomic nuclei. Nuclei contain protons and neutrons, which are collectively known as nucleons. The total number of nucleons, A, is the nucleus's atomic mass number. The number of protons, Z , is the atomic number. The number of neutrons equals $A - Z$. Isotopes are nuclei with the same Z, but with different numbers of neutrons. For an element X, an isotope of given Z and A is represented by

∮Χ.

The nuclear radius is approximately proportional to $A^{\frac{1}{3}}$, indicating that all nuclei have about the same density. Nuclear masses are specified in unified atomic mass units (u), where the mass of ${}^{12}_{6}C$ (including its 6 electrons) is defined as exactly 12.000000 u, or in terms of their energy equivalent (because $E = mc^2$), where

$$
1\,\mathrm{u} = 931.5\,\mathrm{MeV}/c^2 = 1.66 \times 10^{-27}\,\mathrm{kg}
$$

The mass of a stable nucleus is less than the sum of the masses of its constituent nucleons. The difference in mass (times c^2) is the **total binding energy**. It represents the energy needed to break the nucleus into its constituent nucleons. The binding energy per nucleon averages about 8 MeV per nucleon, and is lowest for low mass and high mass nuclei.

Unstable nuclei undergo radioactive decay; they change into other nuclei with the emission of an α , β , or γ particle. An α particle is a ⁴₂He nucleus; a β particle is an electron or positron; and a γ ray is a high-energy photon. In β decay, a neutrino is also emitted. The transformation of the parent into the daughter nucleus is called transmutation of the elements. Radioactive decay occurs spontaneously only when the rest mass of the products is less than the mass of the parent nucleus. The loss in mass appears as kinetic energy of the products.

Nuclei are held together by the strong nuclear force. The weak nuclear force makes itself apparent in β decay. These two forces, plus the gravitational and electromagnetic forces, are the four known types of force.

Electric charge, linear and angular momentum, mass-energy, and nucleon number are conserved in all decays.

Radioactive decay is a statistical process. For a given type of radioactive nucleus, the number of nuclei that decay (ΔN) in a time Δt is proportional to the number N of parent nuclei present:

$$
\Delta N = -\lambda N \, \Delta t; \tag{30-3a}
$$

the minus sign means N decreases in time.

The proportionality constant λ is called the **decay** constant and is characteristic of the given nucleus. The

Questions

- 1. What do different isotopes of a given element have in common? How are they different?
- 2. What are the elements represented by the X in the following: (a) $^{232}_{92}X$; (b) $^{18}_{7}X$; (c) $^{1}_{1}X$; (d) $^{82}_{38}X$; (e) $^{247}_{97}X$?
- 3. How many protons and how many neutrons do each of the isotopes in Question 2 have?
- 4. Identify the element that has 88 nucleons and 50 neutrons.
- 5. Why are the atomic masses of many elements (see the periodic table) not close to whole numbers?
- 6. How do we know there is such a thing as the strong nuclear force?
- 7. What are the similarities and the differences between the strong nuclear force and the electric force?
- 8. What is the experimental evidence in favor of radioactivity being a nuclear process?
- 9. The isotope ${}^{64}_{29}Cu$ is unusual in that it can decay by γ , β^- , and β^+ emission. What is the resulting nuclide for each case?
- 10. A $^{238}_{92}$ U nucleus decays to a nucleus containing how many neutrons?
- 11. Describe, in as many ways as you can, the difference between α , β , and γ rays.
- 12. What element is formed by the radioactive decay of (a) ${}^{24}_{11}Na(\beta^-)$; (b) ${}^{22}_{11}Na(\beta^+)$; (c) ${}^{210}_{84}Po(\alpha)?$ [Hint: see Appendix B.]
- **13.** What element is formed by the decay of (a) $^{32}_{15}P(\beta^-)$; (b) ${}^{35}_{16}S$ (β ⁻); (c) ${}^{211}_{83}Bi$ (α)? [*Hint*: see Appendix B.]
- 14. Fill in the missing particle or nucleus:
	- (a) $^{45}_{20}Ca \rightarrow ? + e^- + \bar{\nu}$
	- (b) $^{58}_{29}Cu \rightarrow ? + \gamma$
	- (c) $^{46}_{24}Cr \rightarrow ^{46}_{23}V + ?$
	- (d) $^{234}_{94}Pu \rightarrow ? + \alpha$
	- (e) $^{239}_{93}Np \rightarrow ^{239}_{94}Pu + ?$

number N of nuclei remaining after a time t decreases exponentially

$$
N = N_0 e^{-\lambda t}, \tag{30-4}
$$

as does the **activity**, $\Delta N/\Delta t$:

$$
\frac{\Delta N}{\Delta t} = \left(\frac{\Delta N}{\Delta t}\right)_0 e^{-\lambda t}.\tag{30-5}
$$

The **half-life**, $T_{\frac{1}{2}}$, is the time required for half the nuclei of a radioactive sample to decay. It is related to the decay constant bv

$$
T_{\frac{1}{2}} = \frac{0.693}{\lambda}.
$$
 (30-6)

Radioactive decay can be used to determine the age of certain objects.

[*Alpha decay occurs via a purely quantum mechanical process called tunneling through a barrier.]

[*Particle detectors include Geiger counters, scintillators with attached photomultiplier tubes, and semiconductor detectors. Detectors that can image particle tracks include photographic emulsions, bubble chambers, and today wire drift chambers.]

- **15.** Immediately after a ²³⁸₂₉U nucleus decays to ²³⁴₄Th + ⁴He, the daughter thorium nucleus still has 92 electrons circling it. Since thorium normally holds only 90 electrons, what do you suppose happens to the two extra ones?
- **16.** When a nucleus undergoes either β^- or β^+ decay, what happens to the energy levels of the atomic electrons? What is likely to happen to these electrons following the decay?
- 17. The alpha particles from a given alpha-emitting nuclide are generally monoenergetic; that is, they all have the same kinetic energy. But the beta particles from a beta-emitting nuclide have a spectrum of energies. Explain the difference between these two cases.
- 18. Do isotopes that undergo electron capture generally lie above or below the line of stability in Fig. 30–2?
- 19. Can hydrogen or deuterium emit an α particle? Explain.
- 20. Why are many artificially produced radioactive isotopes rare in nature?
- 21. An isotope has a half-life of one month. After two months, will a given sample of this isotope have completely decayed? If not, how much remains?
- 22. Why are none of the elements with $Z > 92$ stable?
- 23. A proton strikes a ${}^{6}_{3}$ Li nucleus. As a result, an α particle and another particle are released. What is the other particle?
- 24. Can ${}^{14}_{6}C$ dating be used to measure the age of stone walls and tablets of ancient civilizations? Explain.
- 25. In both internal conversion and β decay, an electron is emitted. How could you determine which decay process occurred?

Problems

30-1 Nuclear Properties

- 1. (I) A pi meson has a mass of 139 MeV/ c^2 . What is this in atomic mass units?
- 2. (I) What is the approximate radius of an alpha particle $(\frac{4}{3}He)$?
- 3. (II) What is the rest mass of a bare α particle in MeV/ c^2 ?
- 4. (II) (a) What is the approximate radius of a $^{64}_{9}Cu$ nucleus? (b) Approximately what is the value of A for a nucleus whose radius is 3.9×10^{-15} m?
- 5. (II) (a) Show that the density of nuclear matter is essentially the same for all nuclei. (b) What would be the radius of the Earth if it had its actual mass but had the density of nuclei? (c) What would be the radius of a $^{238}_{92}$ U nucleus if it had the density of the Earth?
- 6. (II) (*a*) What is the fraction of the hydrogen atom's mass that is in the nucleus? (b) What is the fraction of the hydrogen atom's volume that is occupied by the nucleus?
- 7. (II) Approximately how many nucleons are there in a 1.0-kg object? Does it matter what the object is made of? Why or why not?
- 8. (III) How much energy must an α particle have to just "touch" the surface of a $^{238}_{92}$ U nucleus?

30-2 Binding Energy

- 9. (I) Estimate the total binding energy for $\frac{40}{20}Ca$, using Fig. 30-1.
- $10.$ (I) Use Fig. 30-1 to estimate the total binding energy of (*a*) $^{238}_{92}U$, and (*b*) $^{84}_{36}Kr$.
- 11. (II) Use Appendix B to calculate the binding energy of H (deuterium).
- 12. (II) Calculate the binding energy per nucleon for a $^{14}_{7}N$ nucleus.
- 13. (II) Determine the binding energy of the last neutron in a $^{40}_{19}$ K nucleus.
- 14. (II) Calculate the total binding energy, and the binding energy per nucleon, for (a) ${}^{6}_{3}$ Li, (b) ${}^{208}_{82}$ Pb. Use Appendix B.
- 15. (II) Compare the average binding energy of a nucleon in $^{23}_{11}$ Na to that in $^{24}_{11}$ Na.
- **16.** (III) How much energy is required to remove (a) a proton, (b) a neutron, from ${}^{16}_{8}O$? Explain the difference in your answers.
- 17. (III) (a) Show that the nucleus ${}^{8}_{4}Be$ (mass = 8.005305 u) is unstable and will decay into two α particles. (b) Is ${}^{12}_{6}C$ stable against decay into three α particles? Show why or why not.

30-3 to 30-7 Radioactive Decay

- **18.** (I) How much energy is released when tritium, ${}^{3}_{1}H$, decays by β^- emission?
- 19. (I) What is the maximum kinetic energy of an electron emitted in the β decay of a free neutron?
- **20.** (I) Show that the decay ${}^{11}_{6}C \rightarrow {}^{10}_{5}B + p$ is not possible because energy would not be conserved.
- **21.** (II) ${}^{22}_{11}$ Na is radioactive. (a) Is it a β^- or β^+ emitter? (b) Write down the decay reaction, and estimate the maximum kinetic energy of the emitted β .
- 22. (II) Give the result of a calculation that shows whether or not the following decays are possible:
	- (a) $^{236}_{92}U \rightarrow ^{235}_{92}U + n$;
	- (b) $^{16}_{8}O \rightarrow ^{15}_{8}O + n$;
	- (c) ${}^{23}_{11}Na \rightarrow {}^{22}_{11}Na + n$.
- **23.** (II) A ²³⁸₉₂U nucleus emits an α particle with kinetic energy = 4.20 MeV. (*a*) What is the daughter nucleus, and (b) what is the approximate atomic mass (in u) of the daughter atom? Ignore recoil of the daughter nucleus.
- **24.** (II) When ${}^{23}_{10}$ Ne (mass = 22.9945 u) decays to ${}^{23}_{11}$ Na $(mass = 22.9898 u)$, what is the maximum kinetic energy of the emitted electron? What is its minimum energy? What is the energy of the neutrino in each case? Ignore recoil of the daughter nucleus.
- 25. (II) A nucleus of mass 238 u, initially at rest, emits an α particle with a KE of 5.0 MeV. What is the KE of the recoiling daughter nucleus?
- 26. (II) What is the maximum KE of the emitted β particle during the decay of $\frac{60}{27}Co$?
- 27. (II) The nuclide ${}^{32}_{15}P$ decays by emitting an electron whose maximum kinetic energy can be 1.71 MeV. (*a*) What is the daughter nucleus? (b) Calculate the daughter's atomic $mass (in u)$.
- **28.** (II) The isotope $^{218}_{84}$ Po can decay by either α or β^- emission. What is the energy release in each case? The mass of $^{218}_{84}$ Po is 218.008965 u.
- 29. (II) How much energy is released in electron capture by beryllium: ${}^{7}_{4}Be + {}^{0}_{-1}e \rightarrow {}^{7}_{3}Li + \nu$?
- 30. (II) A photon with a wavelength of 1.00×10^{-13} m is ejected from an atom. Calculate its energy and explain why it is a γ ray from the nucleus or a photon from the atom.
- 31. (II) Determine the maximum kinetic energy of β^+ particles released when ${}^{11}_{6}C$ decays to ${}^{11}_{5}B$. What is the maximum energy the neutrino can have? What is its minimum energy?
- 32. (II) How much recoil energy does a $^{40}_{19}$ K nucleus get when it emits a 1.46-MeV gamma ray?
- 33. (III) What is the energy of the α particle emitted in the decay ${}^{210}_{84}Po \rightarrow {}^{206}_{82}Pb + \alpha$? Take into account the recoil of the daughter nucleus.
- 34. (III) The α particle emitted when ²³⁸₉₂U decays has 4.20 MeV of kinetic energy. Calculate the recoil kinetic energy of the daughter nucleus and the Q-value of the decay.
- 35. (III) Show that when a nucleus decays by β^+ decay, the total energy released is equal to

$$
(M_{\rm P} - M_{\rm D} - 2m_{\rm e})c^2
$$
,

where $M_{\rm P}$ and $M_{\rm D}$ are the masses of the parent and daughter atoms (neutral), and m_e is the mass of an electron or positron.

30-8 to 30-11 Half-Life, Decay Rates, Decay Series, Dating

- 36. (I) A radioactive material produces 1280 decays per minute at one time, and 4.6 h later produces 320 decays per minute. What is its half-life?
- 37. (I) (a) What is the decay constant of $^{238}_{92}U$ whose half-life is 4.5×10^9 yr? (b) The decay constant of a given nucleus is 8.2×10^{-5} s⁻¹. What is its half-life?
- **38.** (I) What is the activity of a sample of ${}^{14}_{6}C$ that contains 3.1×10^{20} nuclei?
- **39.** (I) What fraction of a sample of ${}^{68}_{9}$ Ge, whose half-life is about 9 months, will remain after 3.0 yr?
- 40. (I) What fraction of a sample is left after exactly 6 half-lives?
- 41. (II) How many nuclei of $^{238}_{92}$ U remain in a rock if the activity registers 640 decays per second?
- 42. (II) In a series of decays, the nuclide $^{235}_{92}U$ becomes $^{207}_{82}Pb$. How many α and β^- particles are emitted in this series?
- 43. (II) The iodine isotope $^{131}_{531}$ is used in hospitals for diagnosis of thyroid function. If 682μ g are ingested by a patient, determine the activity (a) immediately, (b) 1.0 h later when the thyroid is being tested, and (c) 6 months later. Use Appendix B.
- **44.** (II) $^{124}_{55}Cs$ has a half-life of 30.8 s. (a) If we have 8.8 μ g initially, how many Cs nuclei are present? (b) How many are present 2.0 min later? (c) What is the activity at this time? (d) After how much time will the activity drop to less than about 1 per second?
- 45. (II) Calculate the mass of a sample of pure ${}^{40}_{19}K$ with an initial decay rate of 2.0×10^5 s⁻¹. The half-life of $^{40}_{19}$ K is 1.28×10^9 yr.
- **46.** (II) Calculate the activity of a pure 9.7- μ g sample of $^{32}_{15}P$ $(T_{\frac{1}{2}} = 1.23 \times 10^6 \text{ s}).$
- 47. (II) The activity of a sample of $^{35}_{16}S$ ($T_{\frac{1}{2}} = 7.55 \times 10^6$ s) is 2.65×10^5 decays per second. What is the mass of the sample?
- **48.** (II) A sample of $^{233}_{92}U$ ($T\frac{1}{5} = 1.59 \times 10^5 \text{ yr}$) contains 7.50×10^{19} nuclei. (a) What is the decay constant? (b) Approximately how many disintegrations will occur per minute?

General Problems

- 58. Which radioactive isotope of lead is being produced in a reaction where the measured activity of a sample drops to 1.050% of its original activity in 4.00 h?
- 59. An old wooden tool is found to contain only 6.0% of ${}^{14}_{6}C$ that a sample of fresh wood would. How old is the tool?
- 60. A neutron star consists of neutrons at approximately nuclear density. Estimate, for a 10-km-diameter neutron star, (a) its mass number, (b) its mass (kg) , and (c) the acceleration of gravity at its surface.
- $\overline{49}$. (II) The activity of a sample drops by a factor of 10 in 8.6 minutes. What is its half-life?
- 50. (II) A 285-g sample of pure carbon contains 1.3 parts in 10^{12} (atoms) of $^{14}_{6}$ C. How many disintegrations occur per second?
- 51. (II) A sample of ${}^{40}_{19}K$ is decaying at a rate of 6.70×10^2 decays/s. What is the mass of the sample?
- 52. (II) The rubidium isotope ${}^{87}_{37}$ Rb, a β emitter with a halflife of 4.75×10^{10} yr, is used to determine the age of rocks and fossils. Rocks containing fossils of ancient animals contain a ratio of ${}^{87}_{38}Sr$ to ${}^{87}_{37}Rb$ of 0.0160. Assuming that there was no $^{87}_{38}$ Sr present when the rocks were formed, estimate the age of these fossils. [Hint: use Eq. $30-3.$]
- 53. (II) Use Fig. 30–11 and calculate the relative decay rates for α decay of $^{218}_{84}$ Po and $^{214}_{84}$ Po.
- 54. (II) ${}^{7}_{4}$ Be decays with a half-life of about 53 d. It is produced in the upper atmosphere, and filters down onto the Earth's surface. If a plant leaf is detected to have 450 decays/s of ${}_{4}^{7}Be$, (a) how long do we have to wait for the decay rate to drop to 15 per second? (b) Estimate the initial mass of ${}_{4}^{7}Be$ on the leaf.
- 55. (II) Two of the naturally occurring radioactive decay sequences start with $^{232}_{90}Th$, and $^{235}_{92}U$. The first five decays of these two sequences are:

$$
\alpha, \beta, \beta, \alpha, \alpha
$$

and

 α , β , α , β , α .

Determine the resulting intermediate daughter nuclei in each case.

- 56. (II) An ancient wooden club is found that contains 290 g of carbon and has an activity of 8.0 decays per second. Determine its age assuming that in living trees the ratio of ¹⁴C/¹²C atoms is about 1.3 \times 10⁻¹².
- 57. (III) At $t = 0$, a pure sample of radioactive nuclei contains N_0 nuclei whose decay constant is λ . Determine a formula for the number of daughter nuclei, N_D , as a function of time; assume the daughter is stable and that $N_{\rm D} = 0$ at $t = 0$.
- 61. The ${}_{1}^{3}H$ isotope of hydrogen, which is called *tritium* (because it contains three nucleons), has a half-life of 12.33 yr. It can be used to measure the age of objects up to about 100 yr. It is produced in the upper atmosphere by cosmic rays and brought to Earth by rain. As an application, determine approximately the age of a bottle of wine whose ${}^{3}_{1}H$ radiation is about ${}^{1}_{10}$ that present in new wine.
- Some elementary particle theories (Section 32-11) suggest 62. that the proton may be unstable, with a half-life $\geq 10^{32}$ yr. How long would you expect to wait for one proton in your body to decay (consider that your body is all water)?
- 63. How long must you wait (in half-lives) for a radioactive sample to drop to 1.00% of its original activity?
- 64. If the potassium isotope ${}^{40}_{19}K$ gives 60 decays/s in a liter of milk, estimate how much ${}^{40}_{19}$ K and regular ${}^{39}_{19}$ K are in a liter of milk. Use Appendix B.
- 65. (a) In α decay of, say, a $^{226}_{88}$ Ra nucleus, show that the nucleus carries away a fraction $1/(1 + \frac{1}{4}A_D)$ of the total energy available, where A_D is the mass number of the daughter nucleus. [Hint: use conservation of momentum as well as conservation of energy.] (b) Approximately what percentage of the energy available is thus carried off by the α particle in the case cited?
- 66. Strontium-90 is produced as a nuclear fission product of uranium in both reactors and atomic bombs. Look at its location in the periodic table to see what other elements it might be similar to chemically, and tell why you think it might be dangerous to ingest. It has too many neutrons, and it decays with a half-life of about 29 yr. How long will we have to wait for the amount of $^{90}_{38}$ Sr on the Earth's surface to reach 1% of its current level, assuming no new material is scattered about? Write down the decay reaction, including the daughter nucleus. The daughter is radioactive: write down its decav.
- 67. The nuclide $^{191}_{76}$ Os decays with β^- energy of 0.14 MeV accompanied by γ rays of energy 0.042 MeV and 0.129 MeV. (a) What is the daughter nucleus? (b) Draw an energy-level diagram showing the ground states of the parent and daughter and excited states of the daughter. To which of the daughter states does β^- decay of $\frac{191}{76}$ Os occur?
- 68. Determine the activities of (a) 1.0 g of $\frac{131}{531}$ (T₃ = 8.02 days) and (b) 1.0 g of $^{238}_{92}U(T_{\frac{1}{2}} = 4.47 \times 10^9 \text{ yr})$.
- 69. Estimate the total binding energy for copper and then estimate the energy, in joules, needed to break a 3.0-g copper penny into its constituent nucleons. [Hint: use Fig. $30-1$.]
- 70. Instead of giving atomic masses for nuclides as in Appendix B, some Tables give the *mass excess*, Δ , defined as $\Delta = M - A$, where A is the atomic number and M is the mass in u. Determine the mass excess, in u and in MeV/c², for: (a) ${}^{4}_{2}$ He; (b) ${}^{12}_{6}$ C; (c) ${}^{107}_{47}$ Ag; (d) ${}^{235}_{29}$ U. (e) From a glance at Appendix B, can you make a generalization about the sign of Δ as a function of Z or A?
- 71. (a) A 92-gram sample of natural carbon contains the usual fraction of ${}^{14}_{6}C$. Estimate how long it will take before there is only one $^{14}_{6}$ C nucleus left. (b) How does the answer in (a) change if the sample is 280 grams? What does this tell you about the limits of carbon dating?
- 72. If the mass of the proton were just a little closer to the mass of the neutron, the following reaction would be possible even at low collision energies:

 $e^- + p \rightarrow n + \nu$.

Why would this situation be catastrophic? By what percentage would the proton's mass have to be increased to make this reaction possible?

- 73. What is the ratio of the kinetic energies for an alpha particle and a beta particle if both make tracks with the same radius of curvature in a magnetic field, oriented perpendicular to the paths of the particles?
- 74. A 1.00-g sample of natural samarium emits α particles at a rate of 120 s⁻¹ due to the presence of $^{147}_{62}$ Sm. The natural abundance of $^{147}_{62}$ Sm is 15%. Calculate the half-life for this decay process.
- **75.** Almost all of naturally occurring uranium is $^{238}_{92}$ U with a half-life of 4.468×10^9 yr. Most of the rest of natural uranium is ²³⁵₉₂U with a half-life of 7.038 \times 10⁸ yr. Today a sample contains $0.72\% \frac{235}{92}U$. (a) What was this percentage 1.0 billion years ago? (b) What percentage of the sample would be $^{235}_{92}$ U in 100 million years?
- 76. A typical banana contains 400 mg of potassium, of which a small fraction is the radioactive isotope $^{40}_{19}$ K (see Appendix B). Estimate the activity of an average banana due to $^{40}_{10}$ K.
- 77. The practical limit for carbon-14 dating is about 60,000 years. If a bone contains 1.0 kg of carbon, and the animal died 60,000 years ago, what is the activity today?
- 78. Decay series, such as that shown in Fig. 30–11, can be classified into four families, depending on whether the mass numbers have the form $4n$, $4n + 1$, $4n + 2$, or $4n + 3$, where *n* is an integer. Justify this statement and show that for a nuclide in any family, all its daughters will be in the same family.

Answers to Exercises

A: 0.0421 u. B: $7.98 \text{ MeV/nucleon.}$ C: 1.37×10^{-11} s⁻¹. **D:** No: $(\frac{1}{2})(\frac{1}{2}) = \frac{1}{4}$ will be left.

Technicians are looking at an MRI image of sections through a patient's body. MRI is one of several powerful types of medical imaging based on physics used by doctors to diagnose illnesses.

This Chapter opens with basic and important physics topics of nuclear reactions, nuclear fission, and nuclear fusion, and how we obtain nuclear energy. Then we examine the health aspects of radiationdosimetry, therapy, and imaging: MRI, PET, and SPET.

51 **CHAPTER**

Nuclear Energy; Effects and Uses of Radiation

e continue our study of nuclear physics in this Chapter. We begin with a discussion of nuclear reactions, after which we examine the important large energy-releasing processes of fission and fusion. The remainder of the Chapter deals with the effects of nuclear radiation when it passes through matter, particularly biological matter, and how radiation is used medically for therapy and diagnosis, including recently developed imaging techniques.

31-1 Nuclear Reactions and the **Transmutation of Elements**

When a nucleus undergoes α or β decay, the daughter nucleus is that of a different element from the parent. The transformation of one element into another, called transmutation, also occurs by means of nuclear reactions. A nuclear reaction is said to occur when a given nucleus is struck by another nucleus, or by a simpler particle such as a γ ray or neutron, so that an interaction takes place. Ernest Rutherford was the first to report seeing a nuclear reaction. In 1919 he observed that some of the α particles passing through nitrogen gas were absorbed and protons emitted. He concluded that nitrogen nuclei had been transformed into oxygen nuclei via the reaction

$$
{}^{4}_{2}\text{He} + {}^{14}_{7}\text{N} \rightarrow {}^{17}_{8}\text{O} + {}^{1}_{1}\text{H},
$$

where ${}_{2}^{4}$ He is an α particle, and ${}_{1}^{1}$ H is a proton.

Since then, a great many nuclear reactions have been observed. Indeed, many of the radioactive isotopes used in the laboratory are made by means of nuclear reactions. Nuclear reactions can be made to occur in the laboratory, but they also occur regularly in nature. In Chapter 30 we saw an example: 14 C is continually being made in the atmosphere via the reaction[†] n + ¹⁴₂N \rightarrow ¹⁴₂C + p.

EXERCISE A Determine the resulting nucleus in the reaction $n + \frac{137}{56}Ba \rightarrow ? + \gamma$.

In any nuclear reaction, both electric charge and nucleon number are conserved. These conservation laws are often useful, as the following Example shows.

CONCEPTUAL EXAMPLE 31-1 Deuterium reaction. A neutron is observed to strike an $^{16}_{8}$ O nucleus, and a deuteron is given off. (A **deuteron**, or **deuterium**, is the isotope of hydrogen containing one proton and one neutron, ${}^{2}_{1}H$; it is sometimes given the symbol d or D.) What is the nucleus that results?

RESPONSE We have the reaction $n + {}^{16}O \rightarrow ? + {}^{2}H$. The total number of nucleons initially is $1 + 16 = 17$, and the total charge is $0 + 8 = 8$. The same totals apply after the reaction. Hence the product nucleus must have $Z = 7$ and $A = 15$. From the periodic table, we find that it is nitrogen that has $Z = 7$, so the nucleus produced is ¹⁵₂N.

Energy and momentum are also conserved in nuclear reactions, and can be used to determine whether a given reaction can occur or not. For example, if the total mass of the products is less than the total mass of the initial particles. this decrease in mass (recall $\Delta E = \Delta m c^2$) is converted to kinetic energy of the outgoing particles. But if the total mass of the products is greater than the total mass of the initial reactants, the reaction requires energy. The reaction will then not occur unless the bombarding particle has sufficient kinetic energy. Consider a nuclear reaction of the general form

$$
a + X \rightarrow Y + b,
$$

where a is a projectile particle (or small nucleus) that strikes nucleus X, producing nucleus Y and particle b (typically, p, n, α , γ). We define the **reaction** energy, or Q -value, in terms of the masses involved, as

 Q -value

Deuterium

$$
Q = (M_a + M_X - M_b - M_Y)c^2.
$$
 (31-1)

These are all rest masses; $M = 0$ for a γ ray. Since energy is conserved, Q is equal to the change in kinetic energy (final minus initial):

Energy conservation

$$
Q = \kappa E_b + \kappa E_Y - \kappa E_a - \kappa E_X.
$$
 (31-2)

In many reactions, $KE_X = 0$ since X is the target nucleus at rest (or nearly so) struck by an incoming particle a. For $Q > 0$, the reaction is said to be exothermic or exoergic; energy is released in the reaction, so the total KE is greater after the reaction than before. If Q is negative $(Q \le 0)$, the reaction is said to be endothermic or endoergic. In this case the final total KE is less than the initial KE, and an energy input is required to make the reaction happen. The energy input comes from the kinetic energy of the initial colliding particles (a and X).

EXAMPLE 31-2 A slow-neutron reaction. The nuclear reaction

$$
n + {}^{10}_{5}B \rightarrow {}^{7}_{3}Li + {}^{4}_{2}He
$$

is observed to occur even when very slow-moving neutrons (mass $M_n = 1.0087 \text{ u}$) strike a boron atom at rest. For a particular reaction in which $KE_n \approx 0$, the outgoing helium M_{He} = 4.0026 u) is observed to have a speed of 9.30 \times 10⁶ m/s. Determine (a) the kinetic energy of the lithium $(M_{Li} = 7.0160 \text{ u})$, and (b) the Q-value of the reaction.

[†]Nuclear reactions are sometimes written in a shortened form: for example, the reaction

 $n + \frac{14}{7}N \rightarrow \frac{14}{6}C + p$

is written

 $1/2N$ (n, p) $1/2C$.

The symbols outside the parentheses on the left and right represent the initial and final nuclei, respectively. The symbols inside the parentheses represent the bombarding particle (first) and the emitted small particle (second).

APPROACH Since the neutron and boron are both essentially at rest, the total momentum before the reaction is zero; momentum is conserved and so must be zero afterward as well. Thus,

$$
M_{\rm Li} v_{\rm Li} = M_{\rm He} v_{\rm He}.
$$

We solve this for v_{Li} and substitute it into the equation for kinetic energy. **SOLUTION** (a) We can use classical KE with little error, rather than relativistic formulas, because $v_{\text{He}} = 9.30 \times 10^6 \text{ m/s}$ is not close to the speed of light c, and v_{Li} will be even less since $M_{\text{Li}} > M_{\text{He}}$. Thus we can write:

$$
\kappa E_{\rm Li} = \frac{1}{2} \, M_{\rm Li} \, v_{\rm Li}^2 = \frac{1}{2} \, M_{\rm Li} \bigg(\frac{M_{\rm He} \, v_{\rm He}}{M_{\rm Li}} \bigg)^2 = \frac{M_{\rm He}^2 \, v_{\rm He}^2}{2 M_{\rm Li}}.
$$

We put in numbers, changing the mass in u to kg and recall that 1.60×10^{-13} J = 1 MeV:

$$
\kappa E_{Li} = \frac{(4.0026 \,\mathrm{u})^2 (1.66 \times 10^{-27} \,\mathrm{kg/u})^2 (9.30 \times 10^6 \,\mathrm{m/s})^2}{2(7.0160 \,\mathrm{u})(1.66 \times 10^{-27} \,\mathrm{kg/u})}
$$

= 1.64 × 10⁻¹³ J = 1.02 MeV.

(b) We are given the data $KE_a = KE_X = 0$ in Eq. 31-2, so $Q = KE_{Li} + KE_{He}$, where

$$
\kappa E_{\text{He}} = \frac{1}{2} M_{\text{He}} v_{\text{He}}^2 = \frac{1}{2} (4.0026 \text{ u}) (1.66 \times 10^{-27} \text{ kg/u}) (9.30 \times 10^6 \text{ m/s})^2
$$

= 2.87 × 10⁻¹³ J = 1.80 MeV.

Hence, $Q = 1.02 \text{ MeV} + 1.80 \text{ MeV} = 2.82 \text{ MeV}$.

EXAMPLE 31-3 Will the reaction "go"? Can the reaction $p + {}^{13}_{6}C \rightarrow {}^{13}_{7}N + n$ occur when ${}^{13}_{6}C$ is bombarded by 2.0-MeV protons?

APPROACH The reaction will "go" if the reaction is exothermic $(Q > 0)$ and even if $Q < 0$ if the input momentum and kinetic energy are sufficient. First we calculate Q from the difference between final and initial masses using Eq. 31-1, and looking up the masses in Appendix B.

SOLUTION The total masses before and after the reaction are:

(We must use the mass of the ${}_{1}^{1}H$ atom rather than that of the bare proton because the masses of ${}^{12}_{6}C$ and ${}^{13}_{7}N$ include the electrons, and we must include an equal number of electron masses on each side of the equation since none are created or destroyed.) The products have an excess mass of

 $(14.014404 - 14.011180)u = 0.003224 u \times 931.5 MeV/u = 3.00 MeV.$

Thus $Q = -3.00 \text{ MeV}$, and the reaction is endothermic. This reaction requires energy, and the 2.0 MeV protons do not have enough to make it go.

NOTE The proton in Example 31–3 would have to have somewhat more than 3.00 MeV of KE to make this reaction go; 3.00 MeV would be enough to conserve energy, but a proton of this energy would produce the $^{13}_{7}N$ and n with no KE and hence no momentum. Since an incident 3.0-MeV proton has momentum, conservation of momentum would be violated. A calculation using conservation of energy and of momentum, as we did in Examples 30–7 and 31–2, shows that the minimum proton energy, called the threshold energy, is 3.23 MeV in this case.

Threshold energy

 $^{239}_{93}$ Np itself decays by β decay to produce plutonium-239.

FIGURE 31-1 Neptunium and plutonium are produced in this series of reactions, after bombardment of $^{238}_{92}$ U by neutrons.

The artificial transmutation of elements took a great leap forward in the 1930s when Enrico Fermi realized that neutrons would be the most effective projectiles for causing nuclear reactions and in particular for producing new elements. Because neutrons have no net electric charge, they are not repelled by positively charged nuclei as are protons or alpha particles. Hence the probability of a neutron reaching the nucleus and causing a reaction is much greater than for charged projectiles,[†] particularly at low energies. Between 1934 and 1936, Fermi and his co-workers in Rome produced many previously unknown isotopes by bombarding different elements with neutrons. Fermi realized that if the heaviest known element, uranium, is bombarded with neutrons, it might be possible to produce new elements with atomic numbers greater than that of uranium. After several years of hard work, it was suspected that two new elements had been produced, neptunium ($Z = 93$) and plutonium ($Z = 94$). The full confirmation that such "transuranic" elements could be produced came several years later at the University of California, Berkeley. The reactions are shown in Fig. $31-1$.

It was soon shown that what Fermi had actually observed when he bombarded uranium was an even stranger process-one that was destined to play an extraordinary role in the world at large. We discuss it in Section $31-2$.

2 Nuclear Fission, Nuclear Reactors

In 1938, the German scientists Otto Hahn and Fritz Strassmann made an amazing discovery. Following up on Fermi's work, they found that uranium bombarded by neutrons sometimes produced smaller nuclei that were roughly half the size of the original uranium nucleus. Lise Meitner and Otto Frisch, two refugees from Nazi Germany working in Scandinavia, quickly realized what had happened: the uranium nucleus, after absorbing a neutron, actually had split into two roughly equal pieces. This was startling, for until then the known nuclear reactions involved knocking out only a tiny fragment (for example, n, p, or α) from a nucleus.

Nuclear Fission and Chain Reactions

This new phenomenon was named **nuclear fission** because of its resemblance to biological fission (cell division). It occurs much more readily for $^{235}_{92}U$ than for the more common $^{238}_{92}U$. The process can be visualized by imagining the uranium nucleus to be like a liquid drop. According to this liquid-drop model, the neutron absorbed by the $^{235}_{92}U$ nucleus gives the nucleus extra internal energy (like heating a drop of water). This intermediate state, or **compound nucleus**, is $^{236}_{90}$ U (because of the absorbed neutron). The extra energy of this nucleus—it is in an excited state—appears as increased motion of the individual nucleons, which causes the nucleus to take on abnormal elongated shapes, Figure 31-2. When the nucleus elongates (in this model) into the shape shown in Fig. 31–2c, the attraction of the two ends via the short-range nuclear force is greatly weakened by the increased separation distance, and the electric repulsive force becomes dominant. So the nucleus splits in two (Fig. $31-2d$). The two resulting nuclei, X_1 and X_2 , are called fission fragments, and in the process a number of neutrons (typically two or three) are also given off. The reaction can be written

$$
n + \frac{235}{92}U \to \frac{236}{92}U \to X_1 + X_2 + \text{neutrons.}
$$
 (31-3)

The compound nucleus, $^{236}_{92}U$, exists for less than 10^{-12} s, so the process occurs very quickly. The two fission fragments more often split the original uranium mass as about $40\% -60\%$ rather than precisely half and half. A typical fission reaction is

$$
n + \frac{235}{92}U \rightarrow \frac{141}{56}Ba + \frac{92}{36}Kr + 3n,\tag{31-4}
$$

although many others also occur.

[†]That is, positively charged particles. Electrons rarely cause nuclear reactions because they do not interact via the strong nuclear force.

866 CHAPTER 31 Nuclear Energy; Effects and Uses of Radiation **CONCEPTUAL EXAMPLE 31–4 Counting nucleons.** Identify the element X in the fission reaction $n + \frac{235}{22}U \rightarrow \frac{A}{Z}X + \frac{93}{38}Sr + 2n$.

RESPONSE The number of nucleons is conserved (Section 30–7). The uranium nucleus with 235 nucleons plus the incoming neutron make $235 + 1 = 236$ nucleons. So there must be 236 nucleons after the reaction. The Sr has 93 nucleons, and the two neutrons make 95 nucleons, so X has $A = 236 - 95 = 141$. Electric charge is also conserved: before the reaction, the total charge is 92e. After the reaction the total charge is $(Z + 38)e$ and must equal 92e. Thus $Z = 92 - 38 = 54$. The element with $Z = 54$ (see Appendix B or the periodic table) is xenon, so the isotope is $^{141}_{54}$ Xe.

EXERCISE B In the fission reaction $n + \frac{235}{92}U \rightarrow \frac{137}{53}I + \frac{96}{39}Y +$ neutrons, how many neutrons are produced?

Figure 31–3 shows the distribution of fission fragments according to mass. Note that only rarely (about 1 in $10⁴$) does a fission result in equal mass fragments (small arrow in Fig. $31-3$).

A tremendous amount of energy is released in a fission reaction because the mass of $^{235}_{92}U$ is considerably greater than the total mass of the fission fragments plus neutrons. This can be seen from the binding-energy-per-nucleon curve of Fig. 30–1; the binding energy per nucleon for uranium is about $7.6 \,\mathrm{MeV/nucleon}$, but for fission fragments that have intermediate mass (in the center portion of the graph, $A \approx 100$, the average binding energy per nucleon is about 8.5 MeV/nucleon. Since the fission fragments are more tightly bound, they have less mass. The difference in mass, or energy, between the original uranium nucleus and the fission fragments is about $8.5 - 7.6 = 0.9 \,\text{MeV}$ per nucleon. Since there are 236 nucleons involved in each fission, the total energy released per fission is

> $(0.9 \text{ MeV/nucleon})(236 \text{ nucleons}) \approx 200 \text{ MeV}.$ $(31-5)$

This is an enormous amount of energy for one single nuclear event. At a practical level, the energy from one fission is, of course, tiny. But if many such fissions could occur in a short time, an enormous amount of energy at the macroscopic level would be available. A number of physicists, including Fermi, recognized that the neutrons released in each fission (Eqs. 31–3 and 4) could be used to create a chain reaction. That is, one neutron initially causes one fission of a uranium nucleus; the two or three neutrons released can go on to cause additional fissions, so the process multiplies as shown schematically in Fig. $31-4$. If a **self-sustaining chain reaction** was actually possible in practice, the enormous energy available in fission could be released on a larger scale.

FIGURE 31-3 Mass distribution of fission fragments from $^{235}_{92}U$ + n. The small arrow indicates equal mass fragments $(\frac{1}{2} \times (236 - 2) = 117)$. Note that the vertical scale is logarithmic.

Energy released per fission

Chain reaction

FIGURE 31-4 Chain reaction.

FIGURE 31-5 Color painting of the first nuclear reactor, built by Fermi under the grandstand of Stagg Field at the University of Chicago. (There are no photographs of the original reactor because of military secrecy.) Natural uranium was used with graphite as moderator. On December 2, 1942, Fermi slowly withdrew the cadmium control rods and the reactor went critical. This first self-sustaining chain reaction was announced to Washington, by telephone, by Arthur Compton who witnessed the event and reported: "The Italian navigator has just landed in the new world." Garv Sheahan, "Birth of the Atomic Age," Chicago (Illinois); 1957. Chicago Historical Society, ICHi-33305.

FIGURE 31-6 If the amount of uranium exceeds the critical mass, as in (b), a sustained chain reaction is possible. If the mass is less than critical, as in (a), most neutrons escape before additional fissions occur, and the chain reaction is not sustained.

Fermi and his co-workers (at the University of Chicago) showed it was possible by constructing the first **nuclear reactor** in 1942 (Fig. $31-5$).

Nuclear Reactors

Several problems have to be overcome to make any nuclear reactor function. First, the probability that a $^{235}_{92}U$ nucleus will absorb a neutron is large only for slow neutrons, but the neutrons emitted during a fission, and which are needed to sustain a chain reaction, are moving very fast. A substance known as a moderator must be used to slow down the neutrons. The most effective moderator will consist of atoms whose mass is as close as possible to that of the neutrons. (To see why this is true, recall from Chapter 7 that a billiard ball striking an equal mass ball at rest can itself be stopped in one collision; but a billiard ball striking a heavy object bounces off with nearly unchanged speed.) The best moderator would thus contain ${}_{1}^{1}H$ atoms. Unfortunately, ${}_{1}^{1}H$ tends to absorb neutrons. But the isotope of hydrogen called *deuterium*, ${}_{1}^{2}H$, does not absorb many neutrons and is thus an almost ideal moderator. Either ${}^{1}_{1}H$ or ${}^{2}_{1}H$ can be used in the form of water. In the latter case, it is heavy water, in which the hydrogen atoms have been replaced by deuterium. Another common moderator is *graphite*, which consists of ${}^{12}_{6}C$ atoms.

A second problem is that the neutrons produced in one fission may be absorbed and produce other nuclear reactions with other nuclei in the reactor, rather than produce further fissions. In a "light-water" reactor, the ¹₁H nuclei absorb neutrons, as does ²³⁸₉₂U to form ²³⁹₉₂U in the reaction $n + {}^{238}_{97}U \rightarrow {}^{239}_{97}U + \gamma$. Naturally occurring uranium[†] contains 99.3% ${}^{238}_{97}U$ and only 0.7% fissionable $^{235}_{92}U$. To increase the probability of fission of $^{235}_{92}U$ nuclei, natural uranium can be enriched to increase the percentage of $^{235}_{92}$ U using processes such as diffusion or centrifugation. Enrichment is not usually necessary for reactors using heavy water as moderator since heavy water doesn't absorb neutrons.

The third problem is that some neutrons will escape through the surface of the reactor core before they can cause further fissions (Fig. $31-6$). Thus the mass of fuel must be sufficiently large for a self-sustaining chain reaction to take place. The minimum mass of uranium needed is called the critical mass. The value of the critical mass depends on the moderator, the fuel $\binom{239}{94}$ Pu may be used instead of $^{235}_{92}$ U), and how much the fuel is enriched, if at all. Typical values are on the order of a few kilograms (that is, not grams nor thousands of kilograms).

To have a self-sustaining chain reaction, on average at least one neutron produced in each fission must go on to produce another fission. The average number of neutrons per fission that do go on to produce further fissions is

868 CHAPTER 31 Nuclear Energy; Effects and Uses of Radiation

⁺²³⁸₉₂U will fission, but only with fast neutrons $\binom{238}{92}$ U is more stable than $\frac{235}{92}$ U). The probability of absorbing a fast neutron and producing a fission is too low to produce a self-sustaining chain reaction.

called the **multiplication factor**, f . For a self-sustaining chain reaction, we must have $f \ge 1$. If $f < 1$, the reactor is "subcritical." If $f > 1$, it is "supercritical" (and could become dangerously explosive). Reactors are equipped with movable control rods (good neutron absorbers like cadmium or boron), whose function is to absorb neutrons and maintain the reactor at just[†] barely "critical," $f = 1$.

Nuclear reactors have been built for use in research and to produce electric power. Fission produces many neutrons and a "research reactor" is basically an intense source of neutrons. These neutrons can be used as projectiles in nuclear reactions to produce nuclides not found in nature, including isotopes used as tracers and for therapy. A "power reactor" is used to produce electric power. The energy released in the fission process appears as heat, which is used to boil water and produce steam to drive a turbine connected to an electric generator (Fig. $31-7$). The core of a nuclear reactor consists of the fuel and a moderator (water in most U.S. commercial reactors). The fuel is usually uranium enriched so that it contains 2 to 4 percent ²³⁵U. Water at high pressure or other liquid (such as liquid sodium) is allowed to flow through the core. The thermal energy it absorbs is used to produce steam in the heat exchanger, so the fissionable fuel acts as the heat input for a heat engine (Chapter 15).

Critical reaction

Types of nuclear reactor

FIGURE 31-7 A nuclear reactor. The heat generated by the fission process in the fuel rods is carried off by hot water or liquid sodium and is used to boil water to steam in the heat exchanger. The steam drives a turbine to generate electricity and is then cooled in the condenser.

There are problems associated with nuclear power plants. Besides the usual thermal pollution associated with any heat engine (Section $15-12$), there is the serious problem of disposal of the radioactive fission fragments produced in the reactor, plus radioactive nuclides produced by neutrons interacting with the structural parts of the reactor. Fission fragments, like their uranium or plutonium parents, have about 50% more neutrons than protons. Nuclei with atomic number in the typical range for fission fragments ($Z \approx 30$ to 60) are stable only if they have more nearly equal numbers of protons and neutrons (see Fig. $30-2$). Hence the highly neutron-rich fission fragments are very unstable and decay radioactively. The accidental release of highly radioactive fission fragments into the atmosphere poses a serious threat to human health (Section $31-4$), as does possible leakage of the radioactive wastes when they are disposed of.

[†]The release of neutrons and subsequent fissions occur so quickly that manipulation of the control rods to maintain $f = 1$ would not be possible if it weren't for the small percentage ($\approx 1\%$) of so-called delayed neutrons. They come from the decay of neutron-rich fission fragments (or their daughters) having lifetimes on the order of seconds—sufficient to allow enough reaction time to operate the control rods and maintain $f = 1$.

Delayed neutrons

FIGURE 31-8 Devastation around Chernobyl in Russia, after the nuclear power plant disaster in 1986.

The accidents at Three Mile Island, Pennsylvania (1979), and at Chernobyl, Russia (1986), have illustrated some of the dangers and have shown that nuclear plants must be constructed, maintained, and operated with great care and precision (Fig. 31–8). Finally, the lifetime of nuclear power plants is limited to 30-some years. due to buildup of radioactivity and the fact that the structural materials themselves are weakened by the intense conditions inside. "Decommissioning" of a power plant could take a number of forms, but the cost of any method of decommissioning a large plant is very great.

So-called **breeder reactors** were proposed as a solution to the problem of limited supplies of fissionable uranium. A breeder reactor is one in which some of the neutrons produced in the fission of $^{235}_{92}U$ are absorbed by $^{238}_{92}U$, and $^{239}_{94}Pu$ is produced via the set of reactions shown in Fig. 31–1. ²³⁹₉₄Pu is fissionable with slow neutrons, so after separation it can be used as a fuel in a nuclear reactor. Thus a breeder reactor "breeds" new fuel[†] ($^{239}_{94}$ Pu) from otherwise useless $^{238}_{92}$ U. Since natural uranium is 99.3 percent $^{238}_{92}U$, this means that the supply of fissionable fuel could be increased by more than a factor of 100. But breeder reactors have the same problems as other reactors, plus other serious problems. Not only is plutonium considered to be a serious health hazard in itself (radioactive with a half-life of 24,000 years), but plutonium produced in a reactor can readily be used in a bomb, increasing the danger of nuclear proliferation and theft of fuel by terrorists to produce a bomb.

Nuclear power presents risks. Other large-scale energy-conversion methods, such as conventional oil and coal-burning steam plants, also present health and environmental hazards; some of them were discussed in Section 15–12, including air pollution, oil spills, and the release of $CO₂$ gas which can trap heat as in a greenhouse to raise the Earth's temperature. The solution to the world's needs for energy is not only technological, but economic and political as well. A major factor surely is to "conserve"—to not waste energy and use as little as possible. "Reduce, reuse, recycle."

EXAMPLE 31-5 Uranium fuel amount. Estimate the minimum amount of $^{235}_{22}$ U that needs to undergo fission in order to run a 1000-MW power reactor per year of continuous operation. Assume an efficiency (Chapter 15) of about 33%.

APPROACH At 33% efficiency, we need $3 \times 1000 \text{ MW} = 3000 \times 10^6 \text{ J/s}$ input. Each fission releases about $200 \,\text{MeV}$ (Eq. 31-5), so we divide the energy for a year by 200 MeV to get the number of fissions needed per year. Then we multiply by the mass of one uranium atom.

SOLUTION For 1000 MW output, the total power generation needs to be 3000 MW, of which 2000 MW is dumped as "waste" heat. Thus the total energy release in 1 yr (3×10^{7} s) from fission needs to be about

 $(3 \times 10^9 \text{ J/s})(3 \times 10^7 \text{ s}) \approx 10^{17} \text{ J}.$

If each fission releases 200 MeV of energy, the number of fissions required is

$$
\frac{(10^{17} \text{ J})}{(2 \times 10^8 \text{ eV/fission})(1.6 \times 10^{-19} \text{ J/eV})} \approx 3 \times 10^{27} \text{ fissions.}
$$

The mass of a single uranium atom is about $(235 \text{ u})(1.66 \times 10^{-27} \text{ kg/u}) \approx$ 4×10^{-25} kg, so the total uranium mass needed is

 $(4 \times 10^{-25}$ kg/fission) $(3 \times 10^{27}$ fissions) ≈ 1000 kg,

or about a ton.

NOTE Since $^{235}_{92}U$ makes up only 0.7% of natural uranium, the yearly requirement for uranium is on the order of a hundred tons. This is orders of magnitude less than coal, both in mass and volume (coal releases 2.8×10^7 J/kg).

[†]A breeder reactor does not produce more fuel than it uses.

EXERCISE C A nuclear-powered submarine needs 6000 kW input power. How many $^{235}_{92}$ U fissions is this per second?

Atom Bomb

The first use of fission, however, was not to produce electric power. Instead, it was first used as a fission bomb (the "atomic bomb"). In early 1940, with Europe already at war, Germany's leader, Adolf Hitler, banned the sale of uranium from the Czech mines he had recently taken over. Research into the fission process suddenly was enshrouded in secrecy. Physicists in the United States were alarmed. A group of them approached Einstein-a man whose name was a household word-to send a letter to President Franklin Roosevelt about the possibilities of using nuclear fission for a bomb far more powerful than any previously known, and inform him that Germany might already have begun development of such a bomb. Roosevelt responded by authorizing the program known as the Manhattan Project, to see if a bomb could be built. Work began in earnest after Fermi's demonstration in 1942 that a sustained chain reaction was possible. A new secret laboratory was developed on an isolated mesa in New Mexico known as Los Alamos. Under the direction of J. Robert Oppenheimer (1904–1967; Fig. $31-9$), it became the home of famous scientists from all over Europe and the United States.

To build a bomb that was subcritical during transport but that could be made supercritical (to produce a chain reaction) at just the right moment, two pieces of uranium were used, each less than the critical mass but together greater than the critical mass. The two masses, kept separate until the moment of detonation, were then forced together quickly by a kind of gun, and a chain reaction of explosive proportions occurred. An alternate bomb detonated conventional explosives (TNT) surrounding a plutonium sphere to compress it by implosion to double its density, making it more than critical and causing a nuclear explosion. The first fission bomb was tested in the New Mexico desert in July 1945. It was successful. In early August, a fission bomb using uranium was dropped on Hiroshima and a second, using plutonium, was dropped on Nagasaki (Fig. 31-10), both in Japan. World War II ended shortly thereafter.

Besides its great destructive power, a fission bomb produces many highly radioactive fission fragments, as does a nuclear reactor. When a fission bomb explodes, these radioactive isotopes are released into the atmosphere and are known as radioactive fallout.

Testing of nuclear bombs in the atmosphere after World War II was a cause of concern, for the movement of air masses spread the fallout all over the globe. Radioactive fallout eventually settles to the Earth, particularly in rainfall, and is absorbed by plants and grasses and enters the food chain. This is a far more serious problem than the same radioactivity on the exterior of our bodies, since α and β particles are largely absorbed by clothing and the outer (dead) layer of skin. But once inside our bodies via food, the isotopes are in direct contact with living cells. One particularly dangerous radioactive isotope is ${}^{90}_{38}Sr$, which is chemically much like calcium and becomes concentrated in bone, where it causes bone cancer and destruction of bone marrow. The 1963 treaty signed by over 100 nations that bans nuclear weapons testing in the atmosphere was motivated because of the hazards of fallout.

31-3 Nuclear Fusion

The mass of every stable nucleus is less than the sum of the masses of its constituent protons and neutrons. For example, the mass of the helium isotope ${}_{2}^{4}$ He is less than the mass of two protons plus the mass of two neutrons, as we saw in Example 30–3. Thus, if two protons and two neutrons were to come together to form a helium nucleus, there would be a loss of mass. This mass loss is manifested in the release of a large amount of energy.

FIGURE 31-9 J. Robert Oppenheimer, on the left, with General Leslie Groves, who was the administrative head of Los Alamos during World War II. The photograph was taken at the Trinity site in the New Mexico desert, where the first atomic bomb was exploded.

FIGURE 31-10 Photo taken a month after the bomb was dropped on Nagasaki. The shacks were constructed afterwards from debris in the ruins

FIGURE 31-11 Average binding energy per nucleon as a function of mass number A for stable nuclei. Same as Fig. 30-1.

Nuclear Fusion; Stars

The process of building up nuclei by bringing together individual protons and neutrons, or building larger nuclei by combining small nuclei, is called nuclear fusion. A glance at Fig. $31-11$ (same as Fig. $30-1$) shows why small nuclei can combine to form larger ones with the release of energy: it is because the binding energy per nucleon is smaller for light nuclei than it is for those of increasing mass (up to about $A \approx 60$). It is believed that many of the elements in the universe were originally formed through the process of fusion (see Chapter 33), and that fusion is today continually taking place within the stars, including our Sun, producing the prodigious amounts of radiant energy they emit.

EXAMPLE 31-6 Fusion energy release. One of the simplest fusion reactions involves the production of deuterium, ${}_{1}^{2}H$, from a neutron and a proton: ${}_{1}^{1}H + n \rightarrow {}_{1}^{2}H + \gamma$. How much energy is released in this reaction?

APPROACH The energy released equals the difference in mass (times c^2) between the initial and final masses.

SOLUTION From Appendix B, the initial rest mass is

 1.007825 u + 1.008665 u = 2.016490 u,

and after the reaction the mass is that of the ${}_{1}^{2}H$, namely 2.014102 u. The mass difference is

 $2.016490 \text{ u} - 2.014102 \text{ u} = 0.002388 \text{ u}$,

so the energy released is

 $(\Delta m)c^2 = (0.002388 \text{ u})(931.5 \text{ MeV/u}) = 2.22 \text{ MeV},$

and it is carried off by the ${}^{2}_{1}H$ nucleus and the γ ray.

The energy output of our Sun is believed to be due principally to the following sequence of fusion reactions:

where the energy released $(Q$ -value) for each reaction is given in parentheses.

The net effect of this sequence, which is called the **proton-proton cycle**, is for four protons to combine to form one ${}_{2}^{4}$ He nucleus plus two positrons, two neutrinos, and two gamma rays:

$$
4\frac{1}{1}\text{H} \rightarrow \frac{4}{2}\text{He} + 2\text{e}^+ + 2\nu + 2\gamma. \tag{31-7}
$$

Note that it takes two of each of the first two reactions (Eqs. $31-6a$ and b) to produce the two ${}_{2}^{3}$ He for the third reaction. So the total energy release for the net reaction, Eq. 31-7, is $(2 \times 0.42 \text{ MeV} + 2 \times 5.49 \text{ MeV} + 12.86 \text{ MeV}) =$ 24.7 MeV. However, each of the two e^+ (Eq. 31–6a) quickly annihilates with an electron to produce $2m_e c^2 = 1.02 \text{ MeV}$; so the total energy released is $(24.7 \text{ MeV} + 2 \times 1.02 \text{ MeV}) = 26.7 \text{ MeV}$. The first reaction, the formation of deuterium from two protons (Eq. 31-6a), has a very low probability, and the infrequency of that reaction serves to limit the rate at which the Sun produces energy.

EXAMPLE 31-7 ESTIMATE Estimating fusion energy. Estimate the energy released if the following reaction occurred: ${}_{1}^{2}H + {}_{1}^{2}H \rightarrow {}_{2}^{4}He$.

APPROACH We use Fig. 31-11.

SOLUTION We see in Fig. 31–11 that each ${}_{1}^{2}H$ has a binding energy of about $1\frac{1}{4}$ MeV/nucleon, which for 2 nuclei of mass 2 is 4 \times ($1\frac{1}{4}$) \approx 5 MeV. The ⁴He has a binding energy per nucleon of about 7 MeV for a total of 4×7 MeV = 28 MeV. Hence the energy release is $28 \text{ MeV} - 5 \text{ MeV} = 23 \text{ MeV}$.

In stars hotter than the Sun, it is more likely that the energy output comes principally from the carbon (or CNO) cycle, which comprises the following sequence of reactions:

It is easy to see (see Problem 35) that no carbon is consumed in this cycle (see first and last equations) and that the net effect is the same as the proton-proton cycle, Eq. 31-7 (plus 1 extra γ). The theory of the proton-proton cycle and of the carbon cycle as the source of energy for the Sun and stars was first worked out by Hans Bethe (1906-2005) in 1939.

CONCEPTUAL EXAMPLE 31-8 Stellar fusion. What is the heaviest element likely to be produced in fusion processes in stars?

RESPONSE Fusion is possible if the final products have more binding energy (less mass) than the reactants, for then there is net release of energy. Since the binding energy curve in Fig. $31-11$ (or Fig. $30-1$) peaks near $A \approx 56$ to 58 which corresponds to iron or nickel, it would not be energetically favorable to produce elements heavier than that. Nevertheless, in the center of massive stars or in supernova explosions, there is enough initial kinetic energy available to drive endothermic reactions that produce heavier elements, as well.

Possible Fusion Reactors

Fusion reactor The possibility of utilizing the energy released in fusion to make a power reactor is very attractive. The fusion reactions most likely to succeed in a reactor involve the isotopes of hydrogen, ${}_{1}^{2}H$ (deuterium) and ${}_{1}^{3}H$ (tritium), and are as follows, with the energy released given in parentheses:

Comparing these energy yields with that for the fission of $^{235}_{92}U$, we can see that the energy released in fusion reactions can be greater for a given mass of fuel than in fission. Furthermore, as fuel, a fusion reactor could use deuterium, which is very plentiful in the water of the oceans (the natural abundance of ${}^{2}_{1}H$ is 0.0115% on average, or about 1 g of deuterium per 80 L of water). The simple proton-proton reaction of Eq. 31-6a, which could use a much more plentiful source of fuel, ${}_{1}^{1}H$, has such a small probability of occurring that it cannot be considered a possibility on Earth.

Although a useful fusion reactor has not yet been achieved, considerable progress has been made in overcoming the inherent difficulties. The problems are associated with the fact that all nuclei have a positive charge and repel each other. However, if they can be brought close enough together so that the short-range attractive nuclear force can come into play, the latter can pull the nuclei together and fusion will occur. For the nuclei to get close enough together, they must have large kinetic energy to overcome the electric repulsion. High kinetic energies are easily attainable with particle accelerators (Chapter 32), but the number of particles involved is too small. To produce realistic amounts of energy, we must deal with matter in bulk, for which high kinetic energy means higher temperatures. Indeed, very high temperatures are required for fusion to occur, and fusion devices are often referred to as thermonuclear devices. The Sun and other stars are very hot, many millions of degrees, so the nuclei are moving fast enough for fusion to take place, and the energy released keeps the temperature high so that further fusion reactions can occur. The Sun and the stars represent huge self-sustaining thermonuclear reactors that stay together because of their great gravitational mass; but on Earth, containment of the fast-moving nuclei at the high temperatures and densities required has proven difficult.

It was realized after World War II that the temperature produced within a fission (or "atomic") bomb was close to 10^8 K. This suggested that a fission bomb could be used to ignite a fusion bomb (popularly known as a thermonuclear or hydrogen bomb) to release the vast energy of fusion. The uncontrollable release of fusion energy in an H-bomb (in 1952) was relatively easy to obtain. But to realize usable energy from fusion at a slow and controlled rate turned out to be a serious challenge.

EXAMPLE 31-9 ESTIMATE Temperature needed for d-t fusion. Estimate the temperature required for deuterium-tritium fusion $(d-t)$ to occur.

APPROACH We assume the nuclei approach head-on, each with kinetic energy KE, and that the nuclear force comes into play when the distance between their centers equals the sum of their nuclear radii. The electrostatic potential energy (Section 17–5) of the two particles at this distance must equal the total kinetic energy of the two particles when far apart. The average kinetic energy is related to Kelvin temperature by Eq. 13-8.
SOLUTION The radii of the two nuclei $(Z_1 = 2 \text{ and } Z_2 = 3)$ are given by Eq. 30–1: $r_d \approx 1.5 \text{ fm}$, $r_t \approx 1.7 \text{ fm}$, so $r_d + r_t = 3.2 \times 10^{-15} \text{ m}$. We equate the kinetic energy of the two initial particles to the potential energy when very close:

$$
2\kappa \varepsilon \approx \frac{1}{4\pi\epsilon_0} \frac{e^2}{(r_d + r_t)}
$$

$$
\approx \left(9.0 \times 10^9 \frac{N \cdot m^2}{C^2}\right) \frac{(1.6 \times 10^{-19} C)^2}{(3.2 \times 10^{-15} m)(1.6 \times 10^{-19} J/eV)} \approx 0.45 MeV.
$$

Thus, $KE \approx 0.22 \text{ MeV}$, and if we ask that the average kinetic energy be this high, then from Eq. 13–8, $\frac{3}{2}kT = \overline{\text{KE}}$, we have

$$
T = \frac{2\overline{\text{KE}}}{3k} = \frac{2(0.22 \text{ MeV})(1.6 \times 10^{-13} \text{ J/MeV})}{3(1.38 \times 10^{-23} \text{ J/K})} \approx 2 \times 10^9 \text{ K}.
$$

NOTE More careful calculations show that the temperature required for fusion is actually about an order of magnitude less than this rough estimate, partly because it is not necessary that the *average* kinetic energy be 0.22 MeV—a small percentage with this much energy (particles in the high-energy tail of the Maxwell distribution, Fig. 13–18) would be sufficient. Reasonable estimates for a usable fusion reactor are in the range $T \approx 2$ to 4×10^8 K.

It is not only a high temperature that is required for a fusion reactor. There must also be a high density of nuclei to ensure a sufficiently high collision rate. A real difficulty with controlled fusion is to contain nuclei long enough and at a high enough density for sufficient reactions to occur that a usable amount of energy is obtained. At the temperatures needed for fusion, the atoms are ionized, and the resulting collection of nuclei and electrons is referred to as a plasma. Ordinary materials vaporize at a few thousand degrees at best, and hence cannot be used to contain a high-temperature plasma. Two major containment techniques are magnetic confinement and inertial confinement.

In magnetic confinement, magnetic fields are used to try to contain the hot plasma. One possibility is a torus-shaped design, Fig. 31-12, originally called a tokamak.

The second method for containing the fuel for fusion is inertial confinement: a small pellet of deuterium and tritium is struck simultaneously from several directions by very intense laser beams (Fig. 31-13). The intense influx of energy heats and ionizes the pellet into a plasma, compressing it and heating it to temperatures at which fusion occurs. The confinement time is on the order of 10^{-11} to 10^{-9} s, during which time the ions do not move appreciably because of their own inertia, fusion takes place, and the pellet explodes.

FIGURE 31-12 Tokamak configuration, showing the total **B** field due to external current plus current in the plasma itself.

FIGURE 31-13 (a) Target chamber (5 m in diameter) of the NOVA laser at Lawrence Livermore Laboratory, into which 10 laser beams converge on a target. (b) A 1-mm-diameter DT (deuterium-tritium) target, on its support, at the center of the target chamber.

31-4 Passage of Radiation Through Matter; **Radiation Damage**

When we speak of *radiation*, we include α , β , γ , and X-rays, as well as protons, neutrons, and other particles such as pions (see Chapter 32). Because charged particles can ionize the atoms or molecules of any material they pass through, they are referred to as **ionizing radiation**. And because radiation produces ionization, it can cause considerable damage to materials, particularly to biological tissue.

Charged particles, such as α and β rays and protons, cause ionization because of electric forces. That is, when they pass through a material, they can attract or repel electrons strongly enough to remove them from the atoms of the material. Since the α and β rays emitted by radioactive substances have energies on the order of 1 MeV (10^4 to 10^7 eV), whereas ionization of atoms and molecules requires on the order of 10 eV, it is clear that a single α or β particle can cause thousands of ionizations.

Neutral particles also give rise to ionization when they pass through materials. For example, X-ray and γ -ray photons can ionize atoms by knocking out electrons by means of the photoelectric and Compton effects (Chapter 27). Furthermore, if a γ ray has sufficient energy (greater than 1.02 MeV), it can undergo pair production: an electron and a positron are produced (Section 27–6). The charged particles produced in all of these processes can themselves go on to produce further ionization. Neutrons, on the other hand, interact with matter mainly by collisions with nuclei, with which they interact strongly. Often the nucleus is broken apart by such a collision, altering the molecule of which it was a part. And the fragments produced can in turn cause ionization.

Radiation passing through matter can do considerable damage. Metals and other structural materials become brittle and their strength can be weakened if the radiation is very intense, as in nuclear reactor power plants and for space vehicles that must pass through areas of intense cosmic radiation.

The radiation damage produced in biological organisms is due primarily to ionization produced in cells. Several related processes can occur. Ions or radicals are produced that are highly reactive and take part in chemical reactions that interfere with the normal operation of the cell. All forms of radiation can ionize atoms by knocking out electrons. If these are bonding electrons, the molecule may break apart, or its structure may be altered so that it does not perform its normal function or may perform a harmful function. In the case of proteins, the loss of one molecule is not serious if there are other copies of it in the cell and additional copies can be made from the gene that codes for it. However, large doses of radiation may damage so many molecules that new copies cannot be made quickly enough, and the cell dies. Damage to the DNA is more serious, since a cell may have only one copy. Each alteration in the DNA can affect a gene and alter the molecule it codes for, so that needed proteins or other materials may not be made at all. Again the cell may die. The death of a single cell is not normally a problem, since the body can replace it with a new one. (There are exceptions, such as neurons, which are *not* replaceable, so their loss is serious.) But if many cells die, the organism may not be able to recover. On the other hand, a cell may survive but be defective. It may go on dividing and produce many more defective cells, to the detriment of the whole organism. Thus radiation can cause cancer—the rapid uncontrolled production of cells.

Radiation damage to biological organisms is often separated into categories. Somatic damage refers to any part of the body except the reproductive organs. Somatic damage affects that particular organism, causing cancer and, at high doses, radiation sickness (characterized by nausea, fatigue, loss of body hair, and other symptoms) or even death. Genetic damage refers to damage to reproductive cells, causing mutations, the majority of which are harmful and are transmitted to future generations. The possible damage done by the medical use of X-rays and other radiation must be balanced against the medical benefits and prolongation of life as a result of their diagnostic use.

 $\left(\bigstar\right)$ PHYSICS APPLIED **Biological damage** 31-5 Measurement of Radiation-Dosimetry

Although the passage of ionizing radiation through the human body can cause considerable damage, radiation can also be used to treat certain diseases, particularly cancer, often by using very narrow beams directed at a cancerous tumor in order to destroy it (Section $31-6$). It is therefore important to be able to quantify the amount, or **dose**, of radiation. This is the subject of **dosimetry**.

The strength of a source can be specified at a given time by stating the source activity, or how many disintegrations occur per second. The traditional unit is the curie (Ci), defined as

1 Ci = 3.70×10^{10} disintegrations per second.

(This figure comes from the original definition as the activity of exactly one gram of radium.) Although the curie is still in common use, the SI unit for source activity is the **becquerel** (Bq), defined as

 $1 Bq = 1$ disintegration/s.

Commercial suppliers of **radionuclides** (radioactive nuclides) specify the activity at a given time. Since the activity decreases over time, more so for short-lived isotopes, it is important to take this into account.

The source activity $(\Delta N/\Delta t)$ is related to the number of radioactive nuclei present, N, and to the half-life, $T_{\frac{1}{2}}$, by (see Section 30–8):

$$
\frac{\Delta N}{\Delta t} = \lambda N = \frac{0.693}{T_{\frac{1}{2}}} N.
$$

EXAMPLE 31-10 Radioactivity taken up by cells. In a certain experiment, 0.016μ Ci of $^{32}_{15}P$ is injected into a medium containing a culture of bacteria. After 1.0 h the cells are washed and a detector that is 70% efficient (counts 70% of emitted β rays) records 720 counts per minute from all the cells. What percentage of the original ${}^{32}_{15}P$ was taken up by the cells?

APPROACH The half-life of $^{32}_{15}P$ is about 14 days (Appendix B), so we can ignore any loss of activity over 1 hour. From the given activity, we find how many β rays are emitted. We can compare 70% of this to the $(720/\text{min})/(60 \text{ s/min}) = 12 \text{ per second detected}.$

SOLUTION The total number of disintegrations per second originally was $(0.016 \times 10^{-6})(3.7 \times 10^{10}) = 590$. The counter could be expected to count 70% of this, or 410 per second. Since it counted $720/60 = 12$ per second, then $12/410 = 0.029$ or 2.9% was incorporated into the cells.

Another type of measurement is the exposure or absorbed dose—that is, the effect the radiation has on the absorbing material. The earliest unit of dosage was the roentgen (R), defined in terms of the amount of ionization produced by the radiation $(1.6 \times 10^{12} \text{ ion pairs per gram of dry air at standard})$ conditions). Today, 1 R is defined as the amount of X or γ radiation that deposits 0.878×10^{-2} J of energy per kilogram of air. The roentgen was largely superseded by another unit of absorbed dose applicable to any type of radiation, the rad: I rad is that amount of radiation which deposits energy at a rate of 1.00×10^{-2} J/kg in any absorbing material. (This is quite close to the roentgen for X- and γ rays.) The proper SI unit for absorbed dose is the gray (Gy):

$$
1 \text{ Gy} = 1 \text{ J/kg} = 100 \text{ rad.}
$$

The absorbed dose depends not only on the strength of a given radiation beam (number of particles per second) and the energy per particle, but also on the type of material that is absorbing the radiation. Bone, for example, absorbs more of the radiation normally used than does flesh, so the same beam passing through a human body deposits a greater dose (in rads or grays) in bone than in flesh.

Source activity

The curie (unit)

The becquerel (unit)

 $(31-9)$

Absorbed dose

The rad (unit)

The gray (unit)

The gray and the rad are physical units of dose—the energy deposited per unit mass of material. They are, however, not the most meaningful units for measuring the biological damage produced by radiation because equal doses of different types of radiation cause differing amounts of damage. For example, 1 rad of α radiation does 10 to 20 times the amount of damage as 1 rad of β or γ rays. This difference arises largely because α rays (and other heavy particles such as protons and neutrons) move much more slowly than β and γ rays of equal energy due to their greater mass. Hence, ionizing collisions occur closer together, so more irreparable damage can be done. The relative biological effectiveness (RBE) or quality factor (QF) of a given type of radiation is defined as the number of rads of X or γ radiation that produces the same biological damage as 1 rad of the given radiation. Table $31-1$ gives the QF for several types of radiation. The numbers are approximate since they depend somewhat on the energy of the particles and on the type of damage that is used as the criterion.

The effective dose can be given as the product of the dose in rads and the QF, and this unit is known as the rem (which stands for rad equivalent man):

The rem (unit)

Effective dose

RBE or OF

This unit is being replaced by the SI unit for "effective dose," the **sievert** (Sv):

effective dose (in rem) = dose (in rad) \times QF.

The sievert (unit)

effective dose (Sv) = dose (Gy) \times QF. $(31-10b)$

 $(31-10a)$

By these definitions, 1 rem (or 1 Sv) of any type of radiation does approximately the same amount of biological damage. For example, 50 rem of fast neutrons does the same damage as 50 rem of γ rays. But note that 50 rem of fast neutrons is only 5 rads, whereas 50 rem of γ rays is 50 rads.

We are constantly exposed to low-level radiation from natural sources: cosmic rays, natural radioactivity in rocks and soil, and naturally occurring radioactive isotopes in our food, such as ${}^{40}_{19}K$. Radon, ${}^{222}_{86}Rn$, is of considerable concern today. It is the product of radium decay and is an intermediate in the decay series from uranium (see Fig. $30-11$). Most intermediates remain in the rocks where formed, but radon is a gas that can escape from rock (and from building material like concrete) to enter the atmosphere we breathe. Although radon is inert chemically (it is a noble gas), it is not inert physically—it decays by alpha emission, and its products, also radioactive, are *not* chemically inert and can attach to the interior of the lung.

The natural radioactive background averages about 0.30 rem (300 mrem) per year per person in the U.S., although there are large variations. From medical X-rays, the average person receives about 50 to 60 mrem per year, giving an average total dose of about 360 mrem (3.6 mSv) per person. Government regulators suggest an upper limit of allowed radiation for an individual in the general populace at about 100 mrem (1 mSv) per year, exclusive of natural sources. It is not known if low doses of radiation increase the chances of cancer or genetic defects, so the attitude today is to play safe and keep the radiation dose as low as possible.

The upper limit for people who work around radiation-in hospitals, in power plants, in research—has been set higher, a maximum of 5 rem (50 mSv) whole-body dose in any one year, and significantly less averaged over more years (below 2 rem/yr averaged over 5 years). To monitor exposure, those people who work around radiation generally carry some type of dosimeter, one common type being a **radiation film badge** which is a piece of film wrapped in light-tight material. The passage of ionizing radiation through the film changes it so that the film is darkened upon development, and so indicates the received dose. Newer types include the *thermoluminescent dosimeter* (TLD). Dosimeters and badges do not protect the worker, but high levels detected suggest reassignment or modified work practices to reduce radiation exposure to acceptable levels.

Large doses of radiation can cause unpleasant symptoms such as nausea, fatigue, and loss of body hair. Such effects are sometimes referred to as radiation sickness. Large doses can be fatal, although the time span of the

Natural radioactivity

Radon

TABLE 31-1 Quality Factor (QF) of **Different Kinds of Radiation**

Film badges and dosimeters

Radiation sickness

878 CHAPTER 31 Nuclear Energy; Effects and Uses of Radiation

dose is important. A short dose of 1000 rem $(10 Sv)$ is nearly always fatal. A 400-rem (4-Sv) dose in a short period of time is fatal in 50% of the cases. However, the body possesses remarkable repair processes, so that a 400-rem dose spread over several weeks is not usually fatal. It will, nonetheless, cause considerable damage to the body.

The effects of low doses over a long time are difficult to determine and are not well known as yet.

CONCEPTUAL EXAMPLE 31-11 Limiting the dose. A worker in an environment with a radioactive source is warned that she is accumulating a dose too quickly and will have to lower her exposure by a factor of ten to continue working for the rest of the year. If the worker is able to work farther away from the source, how much farther away is necessary?

RESPONSE If the energy is radiated uniformly in all directions, then the intensity (dose/area) should decrease as the distance squared, just as it does for sound and light. If she can work four times farther away, the exposure lowers by a factor of sixteen, enough to make her safe.

EXAMPLE 31-12 Whole-body dose. What whole-body dose is received by a 70-kg laboratory worker exposed to a 40-mCi ${}^{60}_{27}$ Co source, assuming the person's body has cross-sectional area 1.5 m² and is normally about 4.0 m from the source for 4.0 h per day? $^{60}_{27}$ Co emits γ rays of energy 1.33 MeV and 1.17 MeV in quick succession. Approximately 50% of the γ rays interact in the body and deposit all their energy. (The rest pass through.)

APPROACH Of the given energy emitted, only a fraction passes through the worker, equal to *her* area divided by the total area over a full sphere of radius 4.0 m (Fig. 31-14).

SOLUTION The total y-ray energy per decay is $(1.33 + 1.17)$ MeV = 2.50 MeV, so the total energy emitted by the source per second is

$$
(0.040 \text{ Ci})(3.7 \times 10^{10} \text{ decays/Ci} \cdot \text{s})(2.50 \text{ MeV}) = 3.7 \times 10^9 \text{ MeV/s}.
$$

The proportion of this intercepted by the body is its 1.5 m^2 area divided by the area of a sphere of radius 4.0 m (Fig. $31-14$):

$$
\frac{1.5 \text{ m}^2}{4\pi r^2} = \frac{1.5 \text{ m}^2}{4\pi (4.0 \text{ m})^2} = 7.5 \times 10^{-3}.
$$

So the rate energy is deposited in the body (remembering that only 50% of the γ rays interact in the body) is

$$
E = \left(\frac{1}{2}\right)(7.5 \times 10^{-3})(3.7 \times 10^{9} \,\text{MeV/s})(1.6 \times 10^{-13} \,\text{J/MeV})
$$

= 2.2 × 10⁻⁶ J/s.

Since $1 Gy = 1 J/kg$, the whole-body dose rate for this 70-kg person is $(2.2 \times 10^{-6} \text{ J/s})/(70 \text{ kg}) = 3.1 \times 10^{-8} \text{ Gy/s}$. In the space of 4.0 h, this amounts to a dose of

$$
(4.0 \text{ h})(3600 \text{ s/h})(3.1 \times 10^{-8} \text{ Gy/s}) = 4.5 \times 10^{-4} \text{ Gy}.
$$

Since QF \approx 1 for gammas, the effective dose (Eq. 31–10b) is 450 μ Sv or (see Eq. $31-9$:

$$
(100 \text{ rad/Gy})(4.5 \times 10^{-4} \text{ Gy})(1) = 45 \text{ mrem} = 0.45 \text{ mSv}.
$$

NOTE This 45-mrem effective dose is almost 50% of the normal allowed dose for a whole year (100 mrem/yr), or 1% of the maximum one year allowance for radiation workers. This worker should not receive such a dose every day and should seek ways to reduce it (shield the source, vary the work, work farther away, etc.).

FIGURE 31-14 Radiation spreads out in all directions. A person 4.0 m away intercepts only a fraction: her cross-sectional area divided by the area of a sphere of radius 4.0 m. Example $31-12$.

Radiation can be very useful (not just a danger)

FIGURE 31-15 Radiation source rotates so that the beam always passes through the diseased tissue, but minimizing the dose in the rest of the body.

PHYSICS APPLIED Tracers in medicine and biology 31-6 Radiation Therapy

The applications of radioactivity and radiation to human beings and other organisms is a vast field that has filled many books. In the medical field there are two basic aspects: (1) radiation therapy—the treatment of disease (mainly cancer)—which we discuss in this Section; and (2) the *diagnosis* of disease, which we discuss in the following Sections of this Chapter.

Radiation can cause cancer. It can also be used to treat it. Rapidly growing cancer cells are especially susceptible to destruction by radiation. Nonetheless, large doses are needed to kill the cancer cells, and some of the surrounding normal cells are inevitably killed as well. It is for this reason that cancer patients receiving radiation therapy often suffer side effects characteristic of radiation sickness. To minimize the destruction of normal cells, a narrow beam of γ or X-rays is often used when a cancerous tumor is well localized. The beam is directed at the tumor, and the source (or body) is rotated so that the beam passes through various parts of the body to keep the dose at any one place as low as possible—except at the tumor and its immediate surroundings, where the beam passes at all times (Fig. $31-15$). The radiation may be from a radioactive source such as ${}^{69}_{27}Co$, or it may be from an X-ray machine that produces photons in the range 200 keV to 5 MeV. Protons, neutrons, electrons, and pions, which are produced in particle accelerators (Section $32-1$), are also being used in cancer therapy.

In some cases, a tiny radioactive source may be inserted directly inside a tumor, which will eventually kill the majority of the cells. A similar technique is used to treat cancer of the thyroid with the radioactive isotope $13I₃$. The thyroid gland concentrates iodine present in the bloodstream, particularly in any area where abnormal growth is taking place. Its intense radioactivity can destroy the defective cells.

Although radiation can increase the lifespan of many patients, it is not always completely effective. It may not be possible to kill all the cancer cells, so a recurrence of the disease is possible. Many cases, especially when the cancerous cells are not well localized in one area, are difficult to treat without damaging healthy organs.

Another application of radiation is for sterilizing bandages, surgical equipment, and even packaged foods, since bacteria and viruses can be killed or deactivated by large doses of radiation.

Tracers and Imaging in Research and Medicine

Radioactive isotopes are commonly used in biological and medical research as tracers. A given compound is artificially synthesized using a radioactive isotope such as $^{14}_{6}$ C or $^{3}_{1}$ H. Such "tagged" molecules can then be traced as they move through an organism or as they undergo chemical reactions. The presence of these tagged molecules (or parts of them, if they undergo chemical change) can be detected by a Geiger or scintillation counter, which detects emitted radiation (see Section 30–13). How food molecules are digested, and to what parts of the body they are diverted, can be traced in this way. Radioactive tracers have been used to determine how amino acids and other essential compounds are synthesized by organisms. The permeability of cell walls to various molecules and ions can he determined using radioactive isotopes: the tagged molecule or ion is injected into the extracellular fluid, and the radioactivity present inside and outside the cells is measured as a function of time.

In a technique known as **autoradiography**, the position of the radioactive isotopes is detected on film. For example, the distribution of carbohydrates produced in the leaves of plants from absorbed $CO₂$ can be observed by keeping the plant in an atmosphere where the carbon atom in the CO₂ is ¹⁴₆C. After a time, a leaf is placed firmly on a photographic plate and the emitted radiation darkens the film most strongly where the isotope is most strongly concentrated (Fig. $31-16a$). Autoradiography using labeled nucleotides (components of DNA) has revealed much about the details of DNA replication $(Fig. 31-16b)$.

For medical diagnosis, the radionuclide commonly used today is $^{99m}_{43}$ Tc, a long-lived excited state of technetium-99 (the "m" in the symbol stands for "metastable" state). It is formed when $^{99}_{42}$ Mo decays. The great usefulness of $^{99m}_{43}$ Tc derives from its convenient half-life of 6 h (short, but not too short) and the fact that it can combine with a large variety of compounds. The compound to be labeled with the radionuclide is so chosen because it concentrates in the organ or region of the anatomy to be studied. Detectors outside the body then record, or image, the distribution of the radioactively labeled compound. The detection can be done by a single detector (Fig. $31-17$) which is moved across the body, measuring the intensity of radioactivity at a large number of points. The image represents the relative intensity of radioactivity at each point. The relative radioactivity is a diagnostic tool. For example, high or low radioactivity may represent overactivity or underactivity of an organ or part of an organ, or in another case may represent a lesion or tumor. More complex gamma cameras make use of many detectors which simultaneously record the radioactivity at many points. The measured intensities can be displayed on a TV or computer monitor, and allow "dynamic" studies (that is, images that change in time) to be performed.

FIGURE 31-16 (a) Autoradiograph of a mature leaf of the squash plant Cucurbita melopepo exposed for 30 s to ${}^{14}CO_2$. The photosynthetic (green) tissue has become radioactive; the nonphotosynthetic tissue of the veins is free of $14C$ and therefore does not blacken the X-ray sheet. This technique is very useful in following patterns of nutrient transport in plants (b) An autoradiograph of a fiber of chromosomal DNA isolated from the mustard plant Arabidopsis thaliana. The dashed arrays of film grains show the Y-shaped growing point of replicating DNA.

FIGURE 31-17 Collimated gamma-ray detector for scanning (moving) over a patient. The collimator is necessary to select γ rays that come in a straight line from the patient. Without the collimator, γ rays from all parts of the body could strike the scintillator, producing a very poor image.

The images formed using the standard techniques of nuclear medicine, as briefly discussed in the previous Section, are produced from radioactive tracer sources within the *volume* of the body. It is also possible to image the radioactive emissions in a single plane or slice through the body using the computed tomography techniques discussed in Section 25–12. A basic gamma camera is moved around the patient to measure the radioactive intensity from the tracer at many points and angles; the data are processed in much the same way as for X-ray CT scans (Section $25-12$). This technique is referred to as single photon emission tomography (SPET).¹

SPET

*Also known as SPECT, "single photon emission computed tomography."

PET

FIGURE 31-18 Positron emission tomography (PET) uses a ring of detectors, typically scintillators with photomultiplier tubes (Section $30-13$), to detect the two annihilation γ rays (e⁺ + e⁻ \rightarrow 2 γ) emitted at 180° to each other.

Another important technique is **positron emission tomography** (PET), which makes use of positron emitters such as ${}^{11}_{6}C$, ${}^{13}_{2}N$, ${}^{15}_{8}O$, and ${}^{18}_{9}F$ whose half-lives are short. These isotopes are incorporated into molecules that, when inhaled or injected, accumulate in the organ or region of the body to be studied. When such a nuclide β decays, the emitted positron travels at most a few millimeters before it collides with a normal electron. In this collision, the positron and electron are annihilated, producing two γ rays (e⁺ + e⁻ \rightarrow 2 γ), each having an energy of 511 keV (= $m_e c^2$). The two γ rays fly off in opposite directions (180° ± 0.25°) since they must have almost exactly equal and opposite momentum to conserve momentum (the momenta of the initial e^+ and e^- are essentially zero compared to the momenta afterwards of the γ rays). Because the photons travel along the same line in opposite directions, their detection in coincidence by rings of detectors surrounding the patient (Fig. $31-18$) readily establishes the line along which the emission took place. If the difference in time of arrival of the two photons could be determined accurately, the actual position of the emitting nuclide along that line could be calculated. Present-day electronics can measure times to at best ± 300 ps, so at the γ ray's speed $(c = 3 \times 10^8 \text{ m/s})$. the actual position could be determined to an accuracy on the order of about $d = vt \approx (3 \times 10^8 \text{ m/s})(300 \times 10^{-12} \text{ s}) \approx 10 \text{ cm}$, which is not very useful. Although there may be future potential for time-of-flight measurements to determine position, today computed tomography techniques are used instead, similar to those for X-ray CT, which can reconstruct PET images with a resolution on the order of 3–5 mm. One big advantage of PET is that no collimators are needed (as for detection of a single photon—see Fig. 31–17). Thus, fewer photons are "wasted" and lower doses can be administered to the patient with PET.

Both PET and SPET systems can give images that relate to biochemistry, metabolism, and function. This is to be compared to X-ray CT scans (Section 25–12), whose images reflect shape and structure—that is, the anatomy of the imaged region.

31–9 Nuclear Magnetic Resonance (NMR) and Magnetic Resonance Imaging (MRI)

NMR

Nuclear magnetic resonance (NMR) is a phenomenon that soon after its discovery in 1946 became a powerful research tool in a variety of fields from physics to chemistry and biochemistry. It is also an important medical imaging technique. We first briefly discuss the phenomenon, and then look at its applications.

We saw in Chapter 28 (Section 28–6) that when atoms are placed in a magnetic field, atomic energy levels split into several closely spaced levels (see Fig. 28-8). Nuclei, too, exhibit these magnetic properties. We will examine only the simplest, the hydrogen (H) nucleus, since it is the one most used, even for medical imaging. The ${}_{1}^{1}H$ nucleus consists of a single proton. Its spin angular momentum (and its magnetic moment), like that of the electron, can take on only two values when placed in a magnetic field: we call these "spin up" (parallel to the field) and "spin down" (antiparallel to the field), as suggested in Fig. 31-19. When a magnetic field is present, the energy of the nucleus splits into two levels as shown in Fig. $31-20$, with the spin up (parallel to field) having the lower energy. (This is like the Zeeman effect for atomic levels, Fig. 28–8.)

The difference in energy, ΔE , between these two levels is proportional to the total magnetic field, B_T , at the nucleus:

$$
\Delta E = kB_{\rm T},
$$

where k is a proportionality constant that is different for different nuclides.

In a standard nuclear magnetic resonance (NMR) setup, the sample to be examined is placed in a static magnetic field. A radiofrequency (RF) pulse of electromagnetic radiation (that is, photons) is applied to the sample. If the frequency, f , of this pulse corresponds precisely to the energy difference between the two energy levels (Fig. 31-20), so that

$$
hf = \Delta E = kB_{\rm T},\tag{31-11}
$$

then the photons of the RF beam will be absorbed, exciting many of the nuclei from the lower state to the upper state. This is a resonance phenomenon, whose photons can be detected, since there is significant absorption only if f is very near $f = kB_T/h$. Hence the name "nuclear magnetic resonance." For free ${}^{1}_{1}H$ nuclei, the frequency is 42.58 MHz for a magnetic field $B_T = 1.0$ T. If the H atoms are bound in a molecule the total magnetic field B_T at the H nuclei will be the sum of the external applied field (B_{ext}) plus the local magnetic field (B_{local}) due to electrons and nuclei of neighboring atoms. Since f is proportional to B_T , the value of f for a given external field will be slightly different for the bound H atoms than for free atoms:

$$
hf = k(B_{\text{ext}} + B_{\text{local}}).
$$

This small change in frequency can be measured, and is called the "chemical shift." A great deal has been learned about the structure of molecules and bonds using such NMR measurements.

For producing medically useful NMR images—now commonly called MRI, or magnetic resonance imaging—the element most used is hydrogen since it is the commonest element in the human body and gives the strongest NMR signals. The experimental apparatus is shown in Fig. 31-21. The large coils set up the static magnetic field, and the RF coils produce the RF pulse of electromagnetic waves (photons) that cause the nuclei to jump from the lower state to the upper one (Fig. $31-20$). These same coils (or another coil) can detect the absorption of energy or the emitted radiation (also of frequency $f = \Delta E/h$, Eq. 31-11) when the nuclei jump back down to the lower state.

 $\left(\bigwedge\right)$ PHYSICS APPLIED **NMR** imaging (MRI)

FIGURE 31-21 Typical NMR imaging setup: (a) diagram; (b) photograph.

SECTION 31-9 Nuclear Magnetic Resonance (NMR) and Magnetic Resonance Imaging (MRI) 883

FIGURE 31-22 A static field that is stronger at the bottom than at the top. The frequency of absorbed or emitted radiation is proportional to B in NMR.

FIGURE 31-23 False-color NMR image (MRI) of a vertical section through the head showing structures in the normal brain.

The formation of a two-dimensional or three-dimensional image can be done using techniques similar to those for computed tomography (Section 25–12). The simplest thing to measure for creating an image is the intensity of absorbed and/or reemitted radiation from many different points of the body, and this would be a measure of the density of H atoms at each point. But how do we determine from what part of the body a given photon comes? One technique is to give the static magnetic field a gradient; that is, instead of applying a uniform magnetic field, B_T , the field is made to vary with position across the width of the sample (or patient). Since the frequency absorbed by the H nuclei is proportional to B_T (Eq. 31–11), only one plane within the body will have the proper value of B_T to absorb photons of a particular frequency f. By varying f, absorption by different planes can be measured. Alternately, if the field gradient is applied *after* the RF pulse, the frequency of the emitted photons will be a measure of where they were emitted. See Fig. 31-22. If a magnetic field gradient in one direction is applied during excitation (absorption of photons) and photons of a single frequency are transmitted, only H nuclei in one thin slice will be excited. By applying a gradient in a different direction, perpendicular to the first, during reemission, the frequency f of the reemitted radiation will represent depth in that slice. Other ways of varying the magnetic field throughout the volume of the body can be used in order to correlate NMR frequency with position.

A reconstructed image based on the density of H atoms (that is, the intensity of absorbed or emitted radiation) is not very interesting. More useful are images based on the rate at which the nuclei decay back to the ground state, and such images can produce resolution of 1 mm or better. This NMR technique (sometimes called spin-echo) produces images of great diagnostic value, both in the delineation of structure (anatomy) and in the study of metabolic processes. An NMR image is shown in Fig. 31–23.

NMR imaging is considered to be noninvasive. We can calculate the energy of the photons involved: as mentioned above, in a 1.0-T magnetic field, $f = 42.58 \text{ MHz}$ for ¹H. This corresponds to an energy of $hf =$ $(6.6 \times 10^{-34} \text{ J} \cdot \text{s})(43 \times 10^{6} \text{ Hz}) \approx 3 \times 10^{-26} \text{ J}$ or about 10^{-7} eV . Since molecular bonds are on the order of 1 eV, it is clear that the RF photons can cause little cellular disruption. This should be compared to X- or γ rays, whose energies are 10^4 to 10^6 eV and thus can cause significant damage. The static magnetic fields, though often large (≈ 0.1 to 1 T), are believed to be harmless (except for people wearing heart pacemakers).

Table 31–2 lists the recently developed techniques we have discussed for imaging the interior of the body, along with the optimum resolution attainable today. Of course, resolution is only one factor that must be considered; it must be remembered that the different imaging techniques provide different types of information, useful for different types of diagnosis.

A nuclear reaction occurs when two nuclei collide and two or more other nuclei (or particles) are produced. In this process, as in radioactivity, transmutation (change) of elements occurs.

The reaction energy or Q -value of a reaction $a + X \rightarrow Y + b$ is

$$
Q = (M_a + M_X - M_b - M_Y)c^2
$$
 (31-1)

$$
= K_{\rm b} + K_{\rm Y} - K_{\rm a} - K_{\rm X}.
$$
 (31-2)

In fission a heavy nucleus such as uranium splits into two intermediate-sized nuclei after being struck by a neutron. $^{235}_{92}U$ is fissionable by slow neutrons, whereas some fissionable nuclei require fast neutrons. Much energy is released in fission because the binding energy per nucleon is lower for heavy nuclei than it is for intermediate-sized nuclei, so the mass of a heavy nucleus is greater than the total mass of its fission products. The fission process releases neutrons, so that a chain reaction is possible. The critical mass is the minimum mass of fuel needed to sustain a chain reaction. In a nuclear reactor or nuclear bomb, a moderator is needed to slow down the released neutrons.

The fusion process, in which small nuclei combine to form larger ones, also releases energy. The energy from our Sun is believed to originate in the fusion reactions known as the proton-proton cycle in which four protons fuse to form a ⁴He nucleus producing over 25 MeV of energy. A useful

Questions

(NOTE: Masses are found in Appendix B.)

- 1. Fill in the missing particles or nuclei:
	- (a) $n + \frac{137}{56}Ba \rightarrow ? + \gamma$; (b) $n + \frac{137}{56}Ba \rightarrow \frac{137}{55}Cs + ?$; (c) d + ${}^{2}_{1}H \rightarrow {}^{4}_{2}He + ?$; (d) $\alpha + {}^{197}_{79}Au \rightarrow ? + d$ where d stands for deuterium.
- **2.** The isotope: $^{32}_{15}P$ is produced by the reaction: $n + ? \rightarrow \frac{32}{15}P + p$. What must be the target nucleus?
- 3. When $^{22}_{11}$ Na is bombarded by deuterons ($^{2}_{1}$ H), an α particle is emitted. What is the resulting nuclide?
- 4. Why are neutrons such good projectiles for producing nuclear reactions?
- 5. A proton strikes a ${}^{20}_{10}$ Ne nucleus, and an α particle is observed to emerge. What is the residual nucleus? Write down the reaction equation.
- **6.** Are fission fragments β^+ or β^- emitters? Explain.
- 7. If $^{235}_{92}U$ released only 1.5 neutrons per fission on the average, would a chain reaction be possible? If so, what would be different?
- 8. $\frac{238}{92}$ U releases an average of 2.5 neutrons per fission compared to 2.9 for $^{239}_{94}$ Pu. Pure samples of which of these two nuclei do you think would have the smaller critical mass? Explain.
- 9. The energy from nuclear fission appears in the form of thermal energy—but the thermal energy of what?
- 10. Why can't uranium be enriched by chemical means?
- 11. How can a neutron, with practically no kinetic energy, excite a nucleus to the extent shown in Fig. 31-2?
- 12. Why would a porous block of uranium be more likely to explode if kept under water rather than in air?

fusion reactor for power generation has not yet proved possible because of the difficulty in containing the fuel (e.g., deuterium) long enough at the high temperature required.

Radiation can cause damage to materials, including biological tissue. Quantifying amounts of radiation is the subject of dosimetry. The curie (Ci) and the becquerel (Bq) are units that measure the source activity or rate of decay of a sample: $1 \text{ Ci} = 3.70 \times 10^{10}$ disintegrations per second, whereas $1 Bq = 1$ disintegration/s. The **absorbed** dose, often specified in rads, measures the amount of energy deposited per unit mass of absorbing material: 1 rad is the amount of radiation that deposits energy at the rate of 10^{-2} J/kg of material. The SI unit of absorbed dose is the **grav**: $1 \text{ Gv} = 1 \text{ J/kg} = 100 \text{ rad}$. The **effective dose** is often specified by the rem = rad \times QF, where QF is the "quality" factor" of a given type of radiation; 1 rem of any type of radiation does approximately the same amount of biological damage. The average dose received per person per year in the United States is about 0.36 rem. The SI unit for effective dose is the **sievert**: $1 \text{ Sv} = 10^2 \text{ rem.}$

[*Nuclear radiation is used in medicine as therapy and for imaging of biological processes, as well as several types of tomographic **imaging** of the human body: PET, SPET, and MRI; the latter makes use of nuclear magnetic resonance (NMR).]

- 13. A reactor that uses highly enriched uranium can use ordinary water (instead of heavy water) as a moderator and still have a self-sustaining chain reaction. Explain.
- 14. Why must the fission process release neutrons if it is to be useful?
- 15. Discuss the relative merits and disadvantages, including pollution and safety, of power generation by fossil fuels, nuclear fission, and nuclear fusion.
- 16. What is the reason for the "secondary system" in a nuclear reactor, Fig. 31-7? That is, why is the water heated by the fuel in a nuclear reactor not used directly to drive the turbines?
- 17. Why are neutrons released in a fission reaction?
- 18. Why do gamma particles penetrate matter more easily than beta particles do?
- 19. A higher temperature is required for deuterium-deuterium ignition than for deuterium-tritium. Explain.
- 20. Light energy emitted by the Sun and stars comes from the fusion process. What conditions in the interior of stars make this possible?
- 21. How do stars, and our Sun, maintain confinement of the plasma for fusion?
- 22. What is the basic difference between fission and fusion?
- 23. People who work around metals that emit alpha particles are trained that there is little danger from proximity or even touching the material, but that they must take extreme precautions against ingesting it. Hence, there are strong rules against eating and drinking while working, and against machining the metal. Why?
- 24. Why is the recommended maximum radiation dose higher for women beyond the child-bearing age than for younger women?
- 25. Radiation is sometimes used to sterilize medical supplies and even food. Explain how it works.

Problems

(NOTE: Masses are found in Appendix B.)

31-1 Nuclear Reactions, Transmutation

- 1. (I) Natural aluminum is all $^{27}_{13}$ Al. If it absorbs a neutron, what does it become? Does it decay by β^+ or β^- ? What will be the product nucleus?
- 2. (I) Determine whether the reaction ${}_{1}^{2}H + {}_{1}^{2}H \rightarrow {}_{2}^{3}He + n$ requires a threshold energy.
- 3. (I) Is the reaction $n + \frac{238}{90}U \rightarrow \frac{239}{90}U + \gamma$ possible with slow neutrons? Explain.
- 4. (II) Does the reaction $p + \frac{7}{3}Li \rightarrow \frac{4}{2}He + \alpha$ require energy, or does it release energy? How much energy?
- 5. (II) Calculate the energy released (or energy input required) for the reaction $\alpha + {}^{9}_{4}Be \rightarrow {}^{12}_{6}C + n$.
- 6. (II) (a) Can the reaction $n + \frac{24}{12}Mg \rightarrow \frac{23}{11}Na + d$ occur if the bombarding particles have 10.00 MeV of kinetic energy? (d stands for deuterium, ${}_{1}^{2}H$.) (b) If so, how much energy is released?
- 7. (II) (a) Can the reaction $p + \frac{7}{3}Li \rightarrow \frac{4}{2}He + \alpha$ occur if the incident proton has kinetic energy = 2500 keV ? (b) If so, what is the total kinetic energy of the products?
- 8. (II) In the reaction $\alpha + \frac{14}{7}N \rightarrow \frac{17}{8}O + p$, the incident α particles have 7.68 MeV of kinetic energy. (a) Can this reaction occur? (b) If so, what is the total kinetic energy of the products? The mass of $^{17}_{8}$ O is 16.999131 u.
- 9. (II) Calculate the *Q*-value for the "capture" reaction $\alpha + {}^{16}_{8}O \rightarrow {}^{20}_{10}Ne + \gamma$.
- 10. (II) Calculate the total kinetic energy of the products of the reaction $d + \frac{13}{6}C \rightarrow \frac{14}{7}N + n$ if the incoming deuteron (d) has $KE = 36.3 \text{ MeV}$.
- 11. (II) Radioactive ${}^{14}_{6}C$ is produced in the atmosphere when a neutron is absorbed by $14N$. Write the reaction and find its *Q*-value.
- 12. (II) An example of a "stripping" nuclear reaction is $d + \frac{6}{3}Li \rightarrow X + p$. (a) What is X, the resulting nucleus? (b) Why is it called a "stripping" reaction? (c) What is the Q-value of this reaction? Is the reaction endothermic or exothermic?
- 13. (II) An example of a "pick-up" nuclear reaction is ${}_{2}^{3}$ He + ${}_{6}^{12}C \rightarrow X + \alpha$. (a) Why is it called a "pickup" reaction? (b) What is the resulting nucleus? (c) What is the Q -value of this reaction? Is the reaction endothermic or exothermic?
- 14. (II) (a) Complete the following nuclear reaction, $p + ? \rightarrow \frac{32}{16}S + \gamma$. (b) What is the Q-value?
- **15.** (II) The reaction $p + {}^{18}_{8}O \rightarrow {}^{18}_{8}F + n$ requires an input of energy equal to 2.453 MeV. What is the mass of $^{18}_{9}F$?

31-2 Nuclear Fission

16. (I) Calculate the energy released in the fission reaction $n + \frac{235}{92}U \rightarrow \frac{88}{38}Sr + \frac{136}{54}Xe + 12n$. Use Appendix B, and assume the initial kinetic energy of the neutron is very small.

- 26. What is the difference between absorbed dose and effective dose? What are the SI units for each?
- * 27. How might radioactive tracers be used to find a leak in a pipe?
- 17. (I) What is the energy released in the fission reaction of Eq. 31–4? (The masses of $^{141}_{56}$ Ba and $^{92}_{36}$ Kr are 140.914411 u and 91.926156 u, respectively.)
- 18. (I) How many fissions take place per second in a 200-MW reactor? Assume 200 MeV is released per fission.
- 19. (II) The energy produced by a fission reactor is about 200 MeV per fission. What fraction of the rest mass of a $^{235}_{90}$ U nucleus is this?
- **20.** (II) Consider the fission reaction $^{235}_{92}U + n \rightarrow$ $\frac{133}{51}Sb + \frac{98}{41}Nb + ?n$. (a) How many neutrons are produced in this reaction? (b) Calculate the energy release. The atomic masses for Sb and Nb isotopes are 132.915250 u and 97.910328 u, respectively.
- **21.** (II) How much mass of $^{238}_{92}U$ is required to produce the same amount of energy as burning 1.0 kg of coal (about 3×10^7 J)?
- 22. (II) Suppose that the electric average power consumption, day and night, in a typical house is 950 W. What initial mass of $^{235}_{92}U$ would have to undergo fission to supply the electrical needs of such a house for a year? (Assume 200 MeV is released per fission, as well as 100% efficiency.)
- **23.** (II) What initial mass of $^{235}_{92}U$ is required to operate a 650-MW reactor for 1 yr? Assume 40% efficiency.
- **24.** (III) Assuming a fission of $^{236}_{92}U$ into two roughly equal fragments, estimate the electric potential energy just as the fragments separate from each other. Assume that the fragments are spherical (see Eq. $30-1$) and compare your calculation to the nuclear fission energy released, about 200 MeV.

31-3 Nuclear Fusion

- 25. (I) What is the average kinetic energy of protons at the center of a star where the temperature is 10^7 K? [*Hint*: use Eq. $13-8.$
- 26. (II) Show that the energy released in the fusion reaction ${}_{1}^{2}H + {}_{1}^{3}H \rightarrow {}_{2}^{4}He + n$ is 17.59 MeV.
- 27. (II) Show that the energy released when two deuterium nuclei fuse to form $\frac{3}{2}$ He with the release of a neutron is 3.27 MeV.
- $28.$ (II) Verify the Q-value stated for each of the reactions of Eqs. 31-6. [*Hint*: be careful with electrons.]
- 29. (II) Calculate the energy release per gram of fuel for the reactions of Eqs. 31-8a, b, and c. Compare to the energy release per gram of uranium in fission.
- 30. (II) How much energy is released when $^{238}_{92}U$ absorbs a slow neutron ($KE \approx 0$) and becomes $^{239}_{92}U$?
- 31. (II) If a typical house requires 950 W of electric power on average, what minimum amount of deuterium fuel would have to be used in a year to supply these electrical needs? Assume the reaction of Eq. 31–8b.
- 32. (II) Show that the energies carried off by the ${}_{2}^{4}$ He nucleus and the neutron for the reaction of Eq. 31-8c are about 3.5 MeV and 14 MeV, respectively. Are these fixed values, independent of the plasma temperature?
- 33. (II) Suppose a fusion reactor ran on "d-d" reactions, Eqs. 31-8a and b. Estimate how much water, for fuel, would be needed per hour to run a 1000-MW reactor, assuming 30% efficiency.
- 34. (III) How much energy (J) is contained in 1.00 kg of water if its natural deuterium is used in the fusion reaction of Eq. 31-8a? Compare to the energy obtained from the burning of 1.0 kg of gasoline, about 5×10^7 J.
- 35. (III) The energy output of massive stars is believed to be due to the *carbon cycle* (see text). (a) Show that no carbon is consumed in this cycle and that the net effect is the same as for the proton-proton cycle. (b) What is the total energy release? (c) Determine the energy output for each reaction and decay. (d) Why does the carbon cycle require a higher temperature (\approx 2 \times 10⁷K) than the proton–proton cycle ($\approx 1.5 \times 10^7$ K)?
- 36. (III) (a) Compare the energy needed for the first reaction of the carbon cycle to that for a deuterium-tritium reaction (Example 31–9). (b) If a deuterium-tritium reaction requires $T \approx 3 \times 10^8$ K, estimate the temperature needed for the first carbon-cycle reaction.

31-5 Dosimetry

- 37. (I) A dose of 4.0 Sv of γ rays in a short period would be lethal to about half the people subjected to it. How many grays is this?
- 38. (I) Fifty rads of α -particle radiation is equivalent to how many rads of X-rays in terms of biological damage?
- 39. (I) How many rads of slow neutrons will do as much biological damage as 75 rads of fast neutrons?
- $40.$ (I) How much energy is deposited in the body of a 65-kg adult exposed to a 2.0-Gy dose?
- 41. (II) A 0.025- μ Ci sample of $^{32}_{15}P$ is injected into an animal for tracer studies. If a Geiger counter intercepts 25% of the emitted β particles, what will be the counting rate, assumed 85% efficient?
- 42. (II) A cancer patient is undergoing radiation therapy in which protons with an energy of 1.2 MeV are incident on a 0.25 -kg tumor. (a) If the patient receives an effective dose of 1.0 rem, what is the absorbed dose? (b) How many protons are absorbed by the tumor? Assume QF \approx 1.

General Problems

- **51.** J. Chadwick discovered the neutron by bombarding ${}_{4}^{9}Be$ with the popular projectile of the day, alpha particles. (a) If one of the reaction products was the then unknown neutron, what was the other product? (b) What is the Q -value of this reaction?
- 52. Fusion temperatures are often given in keV. Determine the conversion factor from kelvins to keV using, as is common in this field, $\overline{KE} = kT$ without the factor $\frac{3}{2}$.
- 53. One means of enriching uranium is by diffusion of the gas UF_6 . Calculate the ratio of the speeds of molecules of this gas containing $^{235}_{92}U$ and $^{238}_{92}U$, on which this process depends.
- 43. (II) A 1.0-mCi source of ${}^{32}_{15}P$ (in NaHPO₄), a β emitter, is implanted in a tumor where it is to administer 36 Gy. The half-life of $^{32}_{15}P$ is 14.3 days, and 1 mCi delivers about 10 mGy/min. Approximately how long should the source remain implanted?
- 44. (II) About 35 eV is required to produce one ion pair in air. Show that this is consistent with the two definitions of the roentgen given in the text.
- 45. (II) ${}^{57}_{77}Co$ emits 122-keV γ rays. If a 70-kg person swallowed 1.85 μ Ci of $\frac{57}{2}$ Co, what would be the dose rate (Gy/day) averaged over the whole body? Assume that 50% of the γ -ray energy is deposited in the body. [Hint: determine the rate of energy deposited in the body and use the definition of the gray.]
- 46. (II) What is the mass of a 1.00- μ Ci ¹⁴₂C source?
- 47. (II) Huge amounts of radioactive $^{131}_{331}$ were released in the accident at Chernobyl in 1986. Chemically, iodine goes to the human thyroid. (Doctors can use it for diagnosis and treatment of thyroid problems.) In a normal thyroid, $^{131}_{531}$ absorption can cause damage to the thyroid. (a) Write down the reaction for the decay of $^{131}_{53}$ L (b) Its half-life is 8.0 d; how long would it take for ingested $^{131}_{53}$ I to become 10% of the initial value? (c) Absorbing 1 mCi of $^{131}_{53}$ I can be harmful; what mass of iodine is this?
- 48. (III) Assume a liter of milk typically has an activity of 2000 pCi due to $^{40}_{19}$ K. If a person drinks two glasses (0.5 L) per day, estimate the total effective dose (in Sv and in rem) received in a year. As a crude model, assume the milk stays in the stomach 12 hr and is then released. Assume also that very roughly 10% of the 1.5 MeV released per decay is absorbed by the body. Compare your result to the normal allowed dose of 100 mrem per year. Make your estimate for (a) a 50-kg adult, and (b) a 5-kg baby.
- (III) Radon gas, $^{222}_{86}$ Rn, is considered a serious health hazard 49. (see discussion in text). It decays by α -emission. (a) What is the daughter nucleus? (b) Is the daughter nucleus stable or radioactive? If the latter, how does it decay, and what is its half-life? (c) Is the daughter nucleus also a noble gas, or is it chemically reacting? (d) Suppose 1.0 ng of $^{222}_{86}$ Rn seeps into a basement. What will be its activity? If the basement is then sealed, what will be the activity 1 month later? [Hint: see Fig. 30-11.]

31-9 NMR

- 50. (II) Calculate the wavelength of photons needed to produce NMR transitions in free protons in a 1.000-T field. In what region of the spectrum does it lie?
- 54. (a) What mass of $^{235}_{92}U$ was actually fissioned in the first atomic bomb, whose energy was the equivalent of about 20 kilotons of TNT (1 kiloton of TNT releases 5×10^{12} J)? (b) What was the actual mass transformed to energy?
- 55. In a certain town the average yearly background radiation consists of 21 mrad of X-rays and γ rays plus 3.0 mrad of particles having a QF of 10. How many rem will a person receive per year on the average?
- 56. Deuterium makes up 0.0115% of natural hydrogen on average. Make a rough estimate of the total deuterium in the Earth's oceans and estimate the total energy released if all of it were used in fusion reactors.
- 57. A shielded γ -ray source yields a dose rate of 0.052 rad/h at a distance of 1.0m for an average-sized person. If workers are allowed a maximum dose of 5.0 rem in 1 year, how close to the source may they operate, assuming a 40-h work week? Assume that the intensity of radiation falls off as the square of the distance. (It actually falls off more rapidly than $1/r^2$ because of absorption in the air, so your answer will give a better-than-permissible value.)
- 58. Radon gas, $^{222}_{86}$ Rn, is formed by α decay. (a) Write the $decay$ equation. (b) Ignoring the kinetic energy of the daughter nucleus (it's so massive), estimate the kinetic energy of the α particle produced. (c) Estimate the momentum of the alpha and of the daughter nucleus. (d) Estimate the kinetic energy of the daughter, and show that your approximation in (b) was valid.
- 59. Consider a system of nuclear power plants that produce 3400 MW. (a) What total mass of $^{235}_{92}U$ fuel would be required to operate these plants for 1 yr, assuming that $200 \,\text{MeV}$ is released per fission? (b) Typically 6% of the $^{235}_{92}$ U nuclei that fission produce $^{90}_{38}$ Sr, a β^- emitter with a half-life of 29 yr. What is the total radioactivity of the ${}^{90}_{38}Sr$, in curies, produced in 1 yr? (Neglect the fact that some of it decays during the 1-yr period.)
- 60. In the net reaction, Eq. $31-7$, for the proton-proton cycle in the Sun, the neutrinos escape from the Sun with energy of about 0.5 MeV. The remaining energy, 26.2 MeV, is available within the Sun. Use this value to calculate the "heat of combustion" per kilogram of hydrogen fuel and compare it to the heat of combustion of coal, about 3×10^7 J/kg.
- 61. Energy reaches Earth from the Sun at a rate of about 1400 W/m². Calculate (a) the total power output of the Sun, and (b) the number of protons consumed per second in the reaction of Eq. $31-7$, assuming that this is the source of all the Sun's energy. (c) Assuming that the Sun's mass of 2.0×10^{30} kg was originally all protons and that all could be involved in nuclear reactions in the Sun's core, how long would you expect the Sun to "glow" at its present rate? See previous Problem.
- 62. Some stars, in a later stage of evolution, may begin to fuse two $^{12}_{6}$ C nuclei into one $^{24}_{12}$ Mg nucleus (*a*) How much energy would be released in such a reaction? (b) What kinetic energy must two carbon nuclei each have when far apart, if they can then approach each other to within 6.0 fm, center-to-center? (c) Approximately what temperature would this require?
- 63. An average adult body contains about 0.10μ Ci of $^{40}_{19}$ K, which comes from food. (a) How many decays occur per second? (b) The potassium decays produce beta particles with energies of around 1.4 MeV. Calculate the dose per year in sieverts for a 50-kg adult. Is this a significant fraction of the 3.6 mSv/year background rate?
- 64. When the nuclear reactor accident occurred at Chernobyl in 1986, 2.0 \times 10⁷ Ci were released into the atmosphere. Assuming that this radiation was distributed uniformly over the surface of the Earth, what was the activity per square meter? (The actual activity was not uniform; even within Europe wet areas received more radioactivity from rainfall).
- 65. A star with a large helium abundance can burn helium in the reaction ${}^{4}_{2}He + {}^{4}_{2}He + {}^{4}_{2}He \rightarrow {}^{12}_{6}C$. What is the Q-value for this reaction?
- 66. A 1.0- μ Ci ¹³⁷₅₅Cs source is used for 2.0 hours by a 75-kg student in a physics lab. Radioactive $^{137}_{55}Cs$ decays by β ⁻ decay with a half-life of 30 years. The average energy of the emitted betas is about 190 keV per decay. The β decay is quickly followed by a γ with an energy of 660 keV. Assuming the student absorbs all emitted energy, what effective dose (in rem) is received during lab?
- 67. A large amount of $^{90}_{38}Sr$ was released during the Chernobyl nuclear reactor accident in 1986. The $^{90}_{38}$ Sr enters the body through the food chain. How long will it take for 90% of the $^{90}_{38}$ Sr released during the accident to decay? See Appendix B.
- 68. Three radioactive sources have the same activity, 25 mCi. Source A emits 1.0-MeV γ rays, source B emits 2.0-MeV γ rays, and source C emits 2.0-MeV alphas. What is the relative danger of these sources?
- 69. A 70-kg patient is to be given a medical test involving the ingestion of $^{99m}_{43}$ Tc (Section 31-7) which decays by emitting a 140-keV gamma. The half-life for this decay is 6 hours. Assuming that about half the gamma photons exit the body without interacting with anything, what must be the initial activity of the Tc sample if the whole-body dose cannot exceed 50 mrem? Make the rough approximation that biological elimination of Tc can be ignored.

Answers to Exercises

 $\mathbf{A:}$ $^{138}_{56}\text{Ba}.$ B: 3 neutrons. **C:** 2×10^{17} .

This computer-generated reconstruction of a proton-antiproton collision at Fermilab (Fig. 32-3) occurred at a combined energy of nearly 2 TeV. It is one of the events that provided evidence for the top quark (1995). The wire drift chamber (Section $30-13$) is in a magnetic field, and the radius

of curvature of the charged particle tracks is a measure of each particle's momentum (Chapter 20).

The white dots are the electric wires of the drift chamber (Fig. 30–16). The colored lines are the particle paths.

The top quark (t) has too brief a lifetime $(\approx 10^{-23} \text{ s})$ to be detected itself, so we look for its possible decay products. Analysis indicates the following interaction and subsequent decays:

The tracks in the photo include jets (groups of particles moving in roughly the same direction), and a muon (μ^-) whose track is the pink one enclosed by a yellow rectangle to make it stand out. After reading this Chapter, try to name each symbol above and comment on whether all conservation laws hold.

Elementary Particles

n the final two Chapters of this book we discuss two of the most exciting areas of contemporary physics: elementary particles in this Chapter, and cosmology and astrophysics in Chapter 33. These are subjects at the forefront of knowledge—elementary particles treats the smallest objects in the universe; cosmology treats the largest (and oldest) aspects of the universe. The reader who wants an understanding of the great beauties of present-day science—and/or wants to be a good citizen—will want to read these Chapters, even if there is not time to cover them in a physics course.

In this penultimate Chapter we discuss elementary particle physics, which represents the human endeavor to understand the basic building blocks of all matter. By the mid-1930s, it was recognized that all atoms can be considered to be made up of neutrons, protons, and electrons. The basic constituents of the universe were no longer considered to be atoms but rather the proton, neutron, and electron. Besides these three "elementary particles," several others were also known: the positron (a positive electron), the neutrino, and the γ particle (or photon), for a total of six elementary particles.

By the 1950s and 1960s many new types of particles similar to the neutron and proton were discovered, as well as many "midsized" particles called *mesons* whose masses were mostly less than nucleon masses but more than the electron mass. Physicists felt that all of these particles could not be fundamental, and must be made up of even smaller constituents, which were given the name *quarks*.

Today, the basic constituents of matter are considered to be quarks (they make up the protons and neutrons of atomic nuclei as well as mesons) and leptons (a class that includes electrons, positrons, and neutrinos); in addition there are the "carriers of force" including *gluons* and the photon. The theory that describes our present view is called the standard model. How we came to our present understanding of elementary particles is the subject of this Chapter.

One of the exciting recent developments of the last few years is an emerging synthesis between the study of elementary particles and astrophysics (Chapter 33). In fact, very recent observations in astrophysics have led to the conclusion that the greater part of the mass-energy content of the universe is not ordinary matter but two mysterious and invisible forms known as "dark matter" and "dark energy" which cannot be explained by the standard model in its present form.

32-1 High-Energy Particles and Accelerators

In the years after World War II, it was found that if the incoming particle in a nuclear reaction has sufficient energy, new types of particles can be produced. The earliest experiments used **cosmic rays**—particles that impinge on the Earth from space. In the laboratory, various types of particle accelerators have been constructed to accelerate protons or electrons, although heavy ions can also be accelerated. These high-energy accelerators have been used to probe the nucleus more deeply, to produce and study new particles, and to give us information about the basic forces and constituents of nature. Because the projectile particles are at high energy, this field is sometimes called high-energy physics.

Wavelength and Resolution

Particles accelerated to high energy can probe the interior of nuclei and nucleons that they strike. An important factor is that faster-moving projectiles can reveal more detail. The wavelength of projectile particles is given by de Broglie's wavelength formula (Eq. $27-8$),

de Broglie wavelength

 $\lambda = \frac{h}{p},$ $(32-1)$

showing that the greater the momentum p of the bombarding particle, the shorter its wavelength. As discussed in Chapter 25 on optical instruments, resolution of details in images is limited by the wavelength: the shorter the wavelength, the finer the detail that can be obtained. This is one reason why particle accelerators of higher and higher energy have been built in recent years: to probe ever deeper into the structure of matter, to smaller and smaller size.

EXAMPLE 32-1 High resolution with electrons. What is the wavelength, and hence the expected resolution, for a beam of 1.3-GeV electrons?

APPROACH Because 1.3 GeV is much larger than the electron rest mass, we must be dealing with relativistic speeds. The momentum of the electrons is found from Eq. 26–10, and the wavelength $\lambda = h/p$.

SOLUTION Each electron has $KE = 1.3 \text{ GeV} = 1300 \text{ MeV}$, which is about 2500 times the rest mass energy of the electron (0.51 MeV/ c^2). Thus we can ignore the term $(m_0c^2)^2$ in Eq. 26–10, $E^2 = p^2c^2 + m_0^2c^4$, and we solve for p:

$$
p = \sqrt{\frac{E^2 - m_0^2 c^4}{c^2}} \approx \sqrt{\frac{E^2}{c^2}} = \frac{E}{c}.
$$

Therefore the de Broglie wavelength is

$$
\lambda = \frac{h}{p} = \frac{hc}{E}
$$

where $E = 1.3$ GeV. Hence

$$
\lambda = \frac{(6.63 \times 10^{-34} \,\text{J} \cdot \text{s})(3.0 \times 10^8 \,\text{m/s})}{(1.3 \times 10^9 \,\text{eV})(1.6 \times 10^{-19} \,\text{J/eV})} = 0.96 \times 10^{-15} \,\text{m},
$$

or 0.96 fm. This resolution of about 1 fm is on the order of the size of nuclei (see Eq. $30-1$).

NOTE The maximum possible resolution of this beam of electrons is far greater than for a light beam in a light microscope ($\lambda \approx 500$ nm).

EXERCISE A What is the wavelength of a proton with $KE = 1.00 \text{ TeV}$?

Another major reason for building high-energy accelerators is that new particles of greater mass can be produced at higher energies, transforming the KE of the colliding particles into massive particles by $E = mc^2$, as we will discuss shortly. Now we look at particle accelerators.

Cyclotron

The cyclotron was developed in 1930 by E. O. Lawrence $(1901-1958; Fig. 32-1)$ at the University of California, Berkeley. It uses a magnetic field to maintain charged ions—usually protons—in nearly circular paths. Although particle physicists no longer use simple cyclotrons, they are used widely in medicine for treating cancer, and their operating principles are useful for understanding modern accelerators. The protons move in a vacuum inside two D-shaped cavities, as shown in Fig. 32–2. Each time they pass into the gap between the "dees," a voltage accelerates them (the electric force), increasing their speed and increasing the radius of curvature of their path in the magnetic field. After many revolutions, the protons acquire high kinetic energy and reach the outer edge of the cyclotron where they strike a target. The protons speed up only when they are in the gap between the dees, and the voltage must be alternating. When protons are moving to the right across the gap in Fig. 32–2, the right dee must be electrically negative and the left one positive. A half-cycle later, the protons are moving to the left, so the left dee must be negative in order to accelerate them.

FIGURE 32-1 Ernest O. Lawrence, around 1930, holding the first cyclotron (we see the vacuum chamber enclosing it).

FIGURE 32-2 Diagram of a cyclotron. The magnetic field, applied by a large electromagnet, points into the page. The protons start at A, the ion source. The field lines shown are for the alternating electric field in the gap at a certain moment.

Cyclotron frequency

FIGURE 32-2 (repeated) Diagram of a cyclotron.

The frequency, f , of the applied voltage must be equal to that of the circulating protons. When ions of charge q are circulating *within* the hollow dees, the net force F on each is due to the magnetic field B, so $F = qvB$, where v is the speed of the ion at a given moment (Eq. $20-4$). The magnetic force is perpendicular to both \vec{v} and \vec{B} and causes the ions to move in circles; the acceleration inside the dees is thus centripetal and equals v^2/r , where r is the radius of the ion's path at a given moment. We use Newton's second law, $F = ma$, and find that

$$
F = ma
$$

$$
qvB = \frac{mv^2}{r}
$$

when the protons are within the dees (not the gap), so

$$
v=\frac{qBr}{m}\cdot
$$

The time required for a complete revolution is the period T and is equal to

$$
T = \frac{\text{distance}}{\text{speed}} = \frac{2 \pi r}{qBr/m} = \frac{2 \pi m}{qB}
$$

Hence the frequency of revolution f is

$$
f = \frac{1}{T} = \frac{qB}{2\pi m}.
$$
\n
$$
(32-2)
$$

This is known as the cyclotron frequency.

EXAMPLE 32-2 Cyclotron. A small cyclotron of maximum radius $R = 0.25$ m accelerates protons in a 1.7-T magnetic field. Calculate (a) the frequency needed for the applied alternating voltage, and (b) the kinetic energy of protons when they leave the cyclotron.

APPROACH The frequency of the protons revolving within the dees (Eq. 32-2) must equal the frequency of the voltage applied across the gap if the protons are going to increase in speed.

SOLUTION (a) From Eq. 32-2,

$$
f = \frac{qB}{2\pi m}
$$

=
$$
\frac{(1.6 \times 10^{-19} \text{ C})(1.7 \text{ T})}{(6.28)(1.67 \times 10^{-27} \text{ kg})} = 2.6 \times 10^7 \text{ Hz} = 26 \text{ MHz},
$$

which is in the radio-wave region of the EM spectrum (Fig. $22-8$). (b) The protons leave the cyclotron at $r = R = 0.25$ m. From $qvB = mv^2/r$ (see above), we have $v = qBr/m$, so

$$
\begin{aligned} \n\text{KE} &= \frac{1}{2}mv^2 = \frac{1}{2}m\frac{q^2B^2R^2}{m^2} = \frac{q^2B^2R^2}{2m} \\ \n&= \frac{(1.6 \times 10^{-19} \text{ C})^2(1.7 \text{ T})^2(0.25 \text{ m})^2}{(2)(1.67 \times 10^{-27} \text{ kg})} = 1.4 \times 10^{-12} \text{ J} = 8.7 \text{ MeV.} \n\end{aligned}
$$

The KE is much less than the rest energy of the proton (938 MeV), so relativity is not needed.

NOTE The magnitude of the voltage applied to the dees does not affect the final energy. But the higher this voltage, the fewer the revolutions required to bring the protons to full energy.

An important aspect of the cyclotron is that the frequency of the applied voltage, as given by Eq. $32-2$, does not depend on the radius r of the particle's path. Thus the frequency does not have to be changed as the protons or ions

start from the source and are accelerated to paths of larger and larger radii. But this is only true at nonrelativistic energies. At higher speeds, the momentum (Eq. 26–4) is $p = m_0 v / \sqrt{1 - v^2/c^2}$, so *m* in Eq. 32–2 has to be replaced
by γm_0 and the cyclotron frequency f (Eq. 32–2) depends on speed *v*. To keep the particles in synch, machines called **synchrocyclotrons** reduce the frequency in time, in parallel with the mass increase, as a packet of charged particles increases in speed and mass at larger orbits.

Synchrotron

Another way to accelerate relativistic particles is to increase the magnetic field B in time so as to keep f (Eq. 32–2) constant as the particles speed up. Such devices are called synchrotrons, and today they can be enormous. At the European Center for Nuclear Research (CERN) in Geneva, Switzerland, the new (2007) Large Hadron Collider (LHC) will be 4.3 km in radius and accelerate protons to 7 TeV. The Tevatron accelerator at Fermilab (the Fermi National Accelerator Laboratory) at Batavia, Illinois, has a radius of 1.0 km. The Tevatron uses superconducting magnets to accelerate protons to about $1000 \text{ GeV} = 1 \text{ TeV}$ (hence its name); $1 \text{TeV} = 10^{12} \text{ eV}$. These large synchrotrons use a narrow ring of magnets (see Fig. 32–3) with each magnet placed at the same radius from the center of the circle. The magnets are interrupted by gaps where high voltage accelerates the particles; another way to describe the acceleration is to say the particles "surf" on a traveling electromagnetic wave within radiofrequency (RF) cavities.

FIGURE 32-3 (a) Aerial view of Fermilab at Batavia, Illinois; the main accelerator is a circular ring 1.0 km in radius. (b) The interior of the tunnel of the main accelerator at Fermilab. The upper (rectangular-shaped) ring of magnets is for the older 500-GeV accelerator. Below it is the ring of superconducting magnets for the 1-TeV Tevatron.

Once charged particles are injected, they must move in a circle of constant radius. This is accomplished by giving them considerable energy initially in a smaller accelerator (the injector), and then slowly increasing the magnetic field as they speed up in the large synchrotron.

One problem of any accelerator is that accelerating electric charges radiate electromagnetic energy (see Chapter 22). Since ions or electrons are accelerated in an accelerator, we can expect considerable energy to be lost by radiation. The effect increases with energy and is especially important in circular machines where centripetal acceleration is present, such as synchrotrons, and hence is called synchrotron radiation. Synchrotron radiation can be useful, however. Intense beams of photons are sometimes needed, and they are usually obtained from an electron synchrotron.

Synchrotron radiation

Synchrotron

Linear Accelerators

Linac In a **linear accelerator** (linac), electrons or ions are accelerated along a straight-line path, Fig. 32-4a, passing through a series of tubular conductors. Voltage applied to the tubes is alternating so that when electrons (say) reach a gap, the tube in front of them is positive and the one they just left is negative. At low speeds, the particles cover less distance in the same amount of time, so the tubes are shorter at first. Electrons, with their small mass, get close to the speed of light quickly, $v \approx c$, and the tubes are nearly equal in length. Linear accelerators are particularly important for accelerating electrons because of the absence of synchrotron radiation. The largest electron linear accelerator is at Stanford (Stanford Linear Accelerator Center, or SLAC), Fig. 32–4b. It is about 3 km (2 mi) long and can accelerate electrons to 50 GeV. Many hospitals have 10-MeV electron linacs that strike a metal foil to produce γ ray photons to irradiate tumors.

Colliding Beams

Colliders

FIGURE 32-4 (a) Diagram of a simple

High-energy physics experiments can be done by allowing a beam of particles from an accelerator to strike a stationary target. But to obtain the maximum possible collision energy from a given accelerator, two beams of particles are accelerated to very high energy and are steered so that they collide head-on. One way to accomplish such colliding beams with a single accelerator is through the use of storage rings, in which oppositely revolving beams can be repeatedly brought into collision with one another at particular points. For example, in the experiments that provided strong evidence for the top quark (see Chapter opening photo and Section 32–9), the Fermilab Tevatron accelerated protons and antiprotons each to 900 GeV, so that the combined energy of head-on collisions was 1.8 TeV.

The largest collider will soon be the Large Hadron Collider (LHC) at CERN, with a circumference of 26.7 km (Fig. 32–5), scheduled to be completed about 2007. The two colliding beams will each carry 7-TeV protons for a total interaction energy of 14 TeV.

FIGURE 32-5 The large circle represents the position of the tunnel, about 100 m below the ground at CERN (near Geneva) on the French-Swiss border, which will house the LHC. The smaller circle shows the position of the Super Proton Synchrotron that will be used for accelerating protons prior to injection into the LHC.

EXAMPLE 32-3 Speed of a 1.0-TeV proton. What is the speed of a 1.0-TeV proton produced at Fermilab?

APPROACH $KE = 1.0 TeV = 1.0 \times 10^{12} eV$ is much greater than the rest mass of the proton, 0.938×10^9 eV, so relativistic calculations must be used. In particular, we use Eq. 26-6:

$$
KE = (\gamma - 1)m_0 c^2 = \frac{m_0 c^2}{\sqrt{1 - v^2/c^2}} - m_0 c^2.
$$

SOLUTION Compared to the KE of 1.0×10^{12} eV, the rest energy $(\approx 10^{-3} \text{ TeV})$ can be neglected, so we write

 $\kappa E = \frac{m_0 c^2}{\sqrt{1 - v^2/c^2}}.$

 $1 - \frac{v^2}{c^2} = \left(\frac{m_0 c^2}{\text{KE}}\right)^2$

Then

or

$$
\frac{v}{c} = \sqrt{1 - \left(\frac{m_0 c^2}{\text{KE}}\right)^2} = \sqrt{1 - \left(\frac{938 \times 10^6 \text{ eV}}{1.0 \times 10^{12} \text{ eV}}\right)^2}
$$

$$
v = 0.9999996c.
$$

The proton is traveling at a speed extremely close to c , the speed of light.

32-2 Beginnings of Elementary Particle Physics-**Particle Exchange**

The accepted model for elementary particles today views quarks and leptons as the basic constituents of ordinary matter. To understand our present-day view we need to begin with the ideas leading up to its formulation.

Elementary particle physics might be said to have begun in 1935 when the Japanese physicist Hideki Yukawa (1907–1981) predicted the existence of a new particle that would in some way mediate the strong nuclear force. To understand Yukawa's idea, we first consider the electromagnetic force. When we first discussed electricity, we saw that the electric force acts over a distance, without contact. To better perceive how a force can act over a distance, we used the idea of a field. The force that one charged particle exerts on a second can be said to be due to the electric field set up by the first. Similarly, the magnetic field can be said to carry the magnetic force. Later (Chapter 22), we saw that electromagnetic (EM) fields can travel through space as waves. Finally, in Chapter 27, we saw that electromagnetic radiation (light) can be considered as either a wave or as a collection of particles called *photons*. Because of this wave-particle duality, it is possible to imagine that the electromagnetic force between charged particles is due to

(1) the EM field set up by one charged particle and felt by the other, or

(2) an exchange of photons (γ particles) between them.

It is (2) that we want to concentrate on here, and a crude analogy for how an exchange of particles could give rise to a force is suggested in Fig. 32-6. In part (a), two children start throwing heavy pillows at each other; each throw and each catch results in the child being pushed backward by the impulse. This is the equivalent of a repulsive force. On the other hand, if the two children exchange pillows by grabbing them out of the other person's hand, they will be pulled toward each other, as when an attractive force acts.

FIGURE 32-6 Forces equivalent to particle exchange. (a) Repulsive force (children throwing pillows at each other). (b) Attractive force (children grabbing pillows from each other's hands).

pillows from each other's hands)

*Just telling you how it is today would not be a scientific discussion; nor would it give understanding-see footnote on page 769.

FIGURE 32-7 Feynman diagram showing a photon acting as the carrier of the electromagnetic force between two electrons. This is sort of an x vs. t graph, with t increasing upward. Starting at the bottom, two electrons approach each other (the distance between them decreases in time). As they get close, momentum and energy get transferred from one to the other, carried by a photon (or, perhaps, by more than one), and the two electrons bounce apart.

For the electromagnetic force, it is photons that are exchanged between two charged particles that give rise to the force between them. A simple diagram describing this photon exchange is shown in Fig. 32–7. Such a diagram, called a Feynman diagram after its inventor, the American physicist Richard Feynman (1918–1988), is based on the theory of quantum electrodynamics (QED).

Figure 32–7 represents the simplest case in OED, in which a single photon is exchanged. One of the charged particles emits the photon and recoils somewhat as a result; and the second particle absorbs the photon. In any collision or *interaction*, energy and momentum are transferred from one charged particle to the other, carried by the photon. The photon is absorbed by the second particle very shortly after it is emitted by the first and is not observable; hence it is referred to as a *virtual* photon, in contrast to one that is free and can be detected by instruments. The photon is said to *mediate*, or *carry*, the electromagnetic force.

By analogy with photon exchange that mediates the electromagnetic force, Yukawa argued in this early theory that there ought to be a particle that mediates the strong nuclear force—the force that holds nucleons together in the nucleus. Yukawa called this predicted particle a meson (meaning "medium mass"). Figure 32-8 is a Feynman diagram showing meson exchange: a meson carrying the strong force between a neutron and a proton.

We can make a rough estimate of the mass of the meson as follows. Suppose the proton on the left in Fig. 32–8 is at rest. For it to emit a meson would require energy (to make the meson's mass) which, coming from nowhere, would violate conservation of energy. But the uncertainty principle allows nonconservation of energy by an amount ΔE if it occurs only for a time Δt given by $(\Delta E)(\Delta t) \approx h/2\pi$. We set ΔE equal to the energy needed to create the mass m of the meson: $\Delta E = mc^2$. Conservation of energy is violated only as long as the meson exists, which is the time Δt required for the meson to pass from one nucleon to the other, where it is absorbed and disappears. If we assume the meson travels at relativistic speed, close to the speed of light c, then Δt need be at most about $\Delta t = d/c$, where d is the maximum distance that can separate the interacting nucleons. Thus we can write

$$
\Delta E \,\Delta t \approx \frac{h}{2\pi}
$$
\n
$$
mc^2 \left(\frac{d}{c}\right) \approx \frac{h}{2\pi}
$$
\n
$$
mc^2 \approx \frac{hc}{2\pi d}.
$$
\n(3)

 $(32-3)$

Particles that mediate or "carry" forces

Mass estimate of exchange particle

FIGURE 32-8 Meson exchange when a proton and neutron interact via the strong nuclear force.

or

Mass of exchange particle

The range of the strong nuclear force (the maximum distance away it can be felt), is small—not much more than the size of a nucleon or small nucleus (see Eq. 30–1)—so let us take $d \approx 1.5 \times 10^{-15}$ m. Then from Eq. 32–3,

$$
mc^2 \approx \frac{hc}{2\pi d} = \frac{(6.6 \times 10^{-34} \,\mathrm{J} \cdot \mathrm{s})(3.0 \times 10^8 \,\mathrm{m/s})}{(6.28)(1.5 \times 10^{-15} \,\mathrm{m})} \approx 2.1 \times 10^{-11} \,\mathrm{J} = 130 \,\mathrm{MeV}.
$$

The mass of the predicted meson, roughly 130 MeV/ c^2 , is about 250 times the electron mass of 0.51 MeV/ c^2 .⁷

Note that since the electromagnetic force has infinite range, Eq. 32-3 with $d = \infty$ tells us that the exchanged particle for the electromagnetic force, the photon, will have zero rest mass, which it does.

Pion

The particle predicted by Yukawa was discovered in cosmic rays by C.F. Powell and G. Occhialini in 1947, and is called the " π " or pi meson, or simply the **pion.** It comes in three charge states: $+$, $-$, or 0. The π^{+} and π^{-} have mass of 139.6 MeV/ c^2 and the π^0 a mass of 135.0 MeV/ c^2 , all close to Yukawa's prediction. All three interact strongly with matter. Reactions observed in the laboratory, using a particle accelerator, include

$$
p + p \rightarrow p + p + \pi^0,
$$

\n
$$
p + p \rightarrow p + n + \pi^+.
$$
\n(32-4)

The incident proton from the accelerator must have sufficient energy to produce the additional mass of the free pion.

Yukawa's theory of pion exchange as carrier of the strong force is now out of date, and has been replaced by *quantum chromodynamics* in which the basic entities are *quarks*, and the basic carriers of the strong force are *gluons*, as we shall discuss shortly. But the basic idea of the earlier theory, that forces can be understood as the exchange of particles, remains valid.

There are four known types of force-or interaction-in nature. The electromagnetic force is carried by the photon, the strong nuclear force by gluons. What about the other two: the weak nuclear force and gravity? These too are believed to be mediated by particles. The particles that transmit the weak force are referred to as the W^+ , W^- , and Z^0 , and were detected in 1983 (Fig. 32–9).

Forces carried by particles even in standard model

FIGURE $32-9$ (a) Computer reconstruction of a Z-particle decay into an electron and a positron $(Z^0 \rightarrow e^+ + e^-)$ whose tracks are shown in white, which took place in the UA1 detector at CERN. (b) Photo of the UA1 detector at CERN as it was being built.

Graviton

The quantum (or carrier) of the gravitational force is called the **graviton**, and if it exists it has not yet been observed. A comparison of the four forces is given in Table 32–1, where they are listed according to their (approximate) relative strengths. Notice that although gravity may be the most obvious force in daily life (because of the huge mass of the Earth), on a nuclear scale it is the weakest of the four forces, and its effect at the particle level can nearly always be ignored.

[†]Until the 1970s, thought to be mesons, but now gluons (see Section 32-10).

The positron, as we saw in Chapters 27 and 30, is basically a positive electron. That is, many of its properties are the same as for the electron, such as mass, but it has the opposite charge. Other quantum numbers that we discuss shortly are also reversed for antiparticles. The positron is said to be the **antiparticle** to the electron. After the positron was discovered in 1932, it was predicted that other particles also ought to have antiparticles. In 1955 the antiparticle to the proton was found, the **antiproton** (\bar{p}) , which carries a negative charge; see Fig. 32–10. (The bar over the p is used to indicate antiparticle.) Soon after, the antineutron (\overline{n}) was found. All particles have antiparticles. But a few, like the photon and the π^0 , do not have distinct antiparticles—we say that they are their own antiparticles.[†]

FIGURE 32-10 Liquid-hydrogen bubblechamber photograph of an antiproton (\bar{p}) colliding with a proton at rest, producing a Xi-anti-Xi pair $(\bar{p} + p \rightarrow \Xi^{-} + \Xi^{+})$ that subsequently decay into other particles. The drawing indicates the assignment of particles to each track, which is based on how or if that particle decays, and on mass values estimated from measurement of momentum (curvature of track in magnetic field) and energy (thickness of track, for example). Neutral particle paths are shown by dashed lines since neutral particles produce no bubbles and hence no tracks.

Antiparticles are produced in nuclear reactions when there is sufficient energy available, and they do not live very long in the presence of matter. For example, a positron is stable when by itself; but if it encounters an electron, the two annihilate each other. The energy of their vanished mass, plus any kinetic energy they possessed, is converted into the energy of γ rays or of other particles. Annihilation also occurs for all other particle-antiparticle pairs.

32–4 Particle Interactions and Conservation Laws

One of the important uses of high-energy accelerators is to study the interactions of elementary particles with each other. As a means of ordering this subnuclear world, the conservation laws are indispensable. The laws of conservation of energy, of momentum, of angular momentum, and of electric charge are found to hold precisely in all particle interactions.

A study of particle interactions has revealed a number of new conservation laws which (just like the old ones) are ordering principles: they help to explain why some reactions occur and others do not. For example, the following reaction has never been found to occur:

 $p + n \rightarrow p + p + \overline{p}$

even though charge, energy, and so on, are conserved $(\bar{p}$ means an antiproton and \leftrightarrow means the reaction does not occur). To understand why such a reaction

[†]Note, for example, that the opposite charge to $Q = 0$ is still zero.

does not occur, physicists hypothesized a new conservation law, the conservation of baryon number. (Baryon number is a generalization of nucleon number, which we saw earlier is conserved in nuclear reactions and decays.) All nucleons are defined to have baryon number $B = +1$, and all antinucleons (antiprotons, antineutrons) have $B = -1$. All other types of particles, such as photons, mesons, and electrons and other leptons, have $B = 0$. The reaction shown at the start of this paragraph does not conserve baryon number since the left side has $B = (+1) + (+1) = +2$, and the right has $B = (+1) + (+1) + (-1) = +1$. On the other hand, the following reaction does conserve B and *does* occur if the incoming proton has sufficient energy:

$$
p + p \to p + p + \overline{p} + p,
$$

$$
B = +1 + 1 = +1 + 1 - 1 + 1.
$$

As indicated, $B = +2$ on both sides of this equation. From these and other reactions, the conservation of baryon number has been established as a basic principle of physics.

Also useful are the conservation laws for the three lepton numbers, associated with weak interactions including decays. In ordinary β decay, an electron or positron is emitted along with a neutrino or antineutrino. In a similar type of decay, a particle known as a " μ " or mu meson, or **muon**, can be emitted instead of an electron. The muon (discovered in 1937) seems to be much like an electron, except its mass is 207 times larger (106 MeV/ c^2). The neutrino (v_e) that accompanies an emitted electron is found to be different from the neutrino (ν_u) that accompanies an emitted muon. Each of these neutrinos has an antiparticle: $\bar{\nu}_e$ and $\bar{\nu}_\mu$. In ordinary β decay we have, for example,

$$
n \to p + e^- + \bar{\nu}_e
$$

but not $n \leftrightarrow p + e^- + \bar{\nu}_\mu$. To explain why these do not occur, the concept of electron lepton number, L_e , was invented. If the electron (e^-) and the electron neutrino (v_e) are assigned $L_e = +1$, and e^+ and \bar{v}_e are assigned $L_e = -1$, whereas all other particles have $L_e = 0$, then all observed decays conserve L_e . For example, in $n \to p + e^- + \bar{\nu}_e$, $L_e = 0$ initially, and $L_e = 0 + (+1) + (-1) = 0$ after the decay. Decays that do not conserve L_e , even though they would obey the other conservation laws, are not observed to occur.

In a decay involving muons, such as

$$
\pi^+ \to \mu^+ + \nu_\mu,
$$

a second quantum number, muon lepton number (L_μ) , is conserved. The μ^- and ν_μ are assigned $L_{\mu} = +1$, and μ^{+} and $\bar{\nu}_{\mu}$ have $L_{\mu} = -1$, whereas other particles have $L_n = 0$. L_n too is conserved in interactions and decays. Similar assignments can be made for the **tau lepton number**, L_{τ} , associated with the τ lepton (discovered in 1976 with mass more than 3000 times the electron mass) and its neutrino, ν_{τ} .

Keep in mind that antiparticles have not only opposite electric charge from their particles, but also opposite B, L_e , L_μ , and L_τ . For example, a neutron has $B = +1$, an antineutron has $B = -1$ (and all the L's are zero).

CONCEPTUAL EXAMPLE 32-4 Lepton number in muon decay. Which of the following decay schemes is possible for muon decay: (a) $\mu^- \to e^- + \bar{\nu}_e$; (b) $\mu^- \to e^- + \bar{\nu}_e + \nu_\mu$; (c) $\mu^- \to e^- + \nu_e$? All of these particles have $L_{\tau} = 0$.

RESPONSE A μ^- has $L_{\mu} = +1$ and $L_c = 0$. This is the initial state, and the final state (after decay) must also have $L_{\mu} = +1$, $L_{\rm e} = 0$. In (*a*), the final state has $L_{\mu} = 0 + 0 = 0$, and $L_{\rm e} = +1 - 1 = 0$; L_{μ} would not be conserved and indeed this decay is not observed to occur. The f $L_{\mu} = 0 + 0 + 1 = +1$ and $L_{e} = +1 - 1 + 0 = 0$, so both L_{μ} and L_{e} are conserved. This is in fact the most common decay mode of the μ^- . Finally, (c) does not occur because L_e (= +2 in the final state) is not conserved, nor is L_μ .

Additional Example

EXAMPLE 32-5 Energy and momentum are conserved. In addition to the "number" conservation laws which help explain the decay schemes of particles, we can also apply the laws of conservation of energy and momentum. The decay of a Σ^+ particle at rest with a rest mass of 1189 MeV/ c^2 (Table 32–2 in the next Section) commonly yields a proton (rest mass of 938 MeV/ c^2) and a neutral pion, π^0 (rest mass of 135 MeV/ c^2):

$$
\Sigma^+ \to p + \pi^0.
$$

What are the kinetic energies of the decay products, assuming the Σ^+ parent particle was at rest?

APPROACH We find the energy release from the change in mass $(E = mc^2)$ as we did for nuclear processes (Eq. 30–2 or 31–1), and apply conservation of energy and momentum.

SOLUTION The energy released, or *Q*-value, is the change in mass times c^2 .

$$
Q = [m_{\Sigma^+} - (m_{\rm p} + m_{\pi^0})]c^2 = [1189 - (938 + 135)]\,\text{MeV} = 116\,\text{MeV}.
$$

This energy Q becomes the kinetic energy of the resulting decay particles, p and π^0 :

$$
Q = \kappa E_p + \kappa E_{\pi^0}
$$

with each particle's kinetic energy related to its momentum by (Eqs. 26–7 and $26-10$:

$$
\kappa E_p = E_p - m_p c^2 = \sqrt{(p_p c)^2 + (m_p c^2)^2} - m_p c^2,
$$

and similarly for the pion. From momentum conservation, the proton and pion have the same magnitude of momentum since the original particle was at rest: $p_p = p_{\pi^0} = p$. Then

$$
Q = 116 \text{ MeV} = \left[\sqrt{(pc)^2 + (938 \text{ MeV})^2} - 938 \text{ MeV}\right] + \left[\sqrt{(pc)^2 + (135 \text{ MeV})^2} - 135 \text{ MeV}\right]
$$

We solved this for pc, which gives $pc = 189 \text{ MeV}$. Substituting into the expression for the kinetic energy, first for the proton, then for the pion we obtain $KE_p = 19 MeV$ and $KE_{\pi^0} = 97 MeV$.

32-5 Neutrinos-Recent Results

The study of neutrinos is a "hot" subject today. Experiments are being carried out in deep underground laboratories, sometimes in deep mine shafts. The thick layer of earth above is meant to filter out all other "background" particles, leaving mainly the very weakly interacting neutrinos to arrive at the detectors.

Two very important results have come to the fore in our young twenty-first century. One result is that the three neutrinos, ν_e , ν_μ , ν_τ , can occasionally change into one another in certain circumstances, a phenomenon called neutrino flavor oscillation (each of the three types being called, whimsically, a different "flavor"). This result suggests that the lepton numbers L_e , L_u , and L_τ are not perfectly conserved. But the sum, $L_e + L_\mu + L_\tau$, is believed to be always conserved.

The second exceptional result has long been speculated on: are neutrinos massless as originally thought, or do they have a nonzero rest mass? Rough upper limits on the masses have been made. But in 2002, astrophysical experiments showed that the sum of all three neutrino masses must be less than about $1 \text{ eV}/c^2$. But can the masses be zero? Not if there are the flavor oscillations discussed above. It seems likely that at least one neutrino type has rest mass of at least 0.05 eV, a remarkable result.

Neutrino oscillations

32-6 Particle Classification

In the decades following the discovery of the π meson in the late 1940s, hundreds of other subnuclear particles were discovered. One way of arranging the particles in categories is according to their interactions, since not all particles interact by means of all four of the forces known in nature (though all interact via gravity). Table 32–2 lists some of the more common particles classified in this way along with many of their properties. The particles listed are those that are stable, and many that are unstable. At the top of the Table are the **gauge bosons** (so-named after the theory that describes them, "gauge theory"), which include the gluons, the photon, and the W and Z particles; these are the particles that mediate the strong, electromagnetic, and weak interactions, respectively.

Next in Table 32-2 are the leptons, which are particles that do not interact via the strong force but do interact via the weak nuclear force. Leptons that carry electric charge also interact via the electromagnetic force. The leptons include the electron, the muon, and the tau, and three types of neutrino: the electron neutrino (ν_e) , the muon neutrino (ν_{μ}) , and the tau neutrino (ν_{τ}) . Each has an antiparticle.

The third category of particle in Table 32-2 is the hadron. Hadrons are those particles that interact via the strong nuclear force. Hence they are said to be strongly interacting particles. They also interact via the other forces, but the strong force predominates at short distances. The hadrons include the proton, neutron, pion, and a large number of other particles. They are divided into two subgroups: **baryons**, which are those particles that have baryon number $+1$ (or -1 in the case of their antiparticles); and **mesons**, which have baryon number $= 0$.

Leptons

Hadrons

Baryons Mesons

TABLE 32-2 Particles (stable under strong decay)¹

[†] See also Table 32-4 for particles with charm and bottomness.

[‡]Neutrinos partake only in the weak interaction. Experimental upper limits on neutrino masses are given in parentheses, as obtained from the WMAP survey (Chapter 33). Detection of neutrinos being transformed into one another suggests that at least one of the neutrinos has a nonzero mass greater than 0.05 eV.

Only a few of the hundreds of hadrons discovered are included in Table 32–2. Notice that the baryons Λ , Σ , Ξ , and Ω all decay to lighter-mass baryons, and eventually to a proton or neutron. All these processes conserve baryon number. Since there is no lighter particle than the proton with $B = +1$, if baryon number is strictly conserved, the proton itself cannot decay and is stable. (But see Section $32-11$.)

The baryon and lepton numbers (B, L_e, L_μ, L_τ) , as well as strangeness S (Section 32-8), as given in Table 32-2 are for particles; their antiparticles have opposite sign for these numbers.

Many particles listed in Table 32–2 are unstable. The lifetime of an unstable

particle depends on which force is most active in causing the decay. When a stronger force influences a decay, that decay occurs more quickly. Decays caused by the weak force typically have lifetimes of 10^{-13} s or longer (W and Z are exceptions). Decays via the electromagnetic force have much shorter lifetimes, typically about 10^{-16} to 10^{-19} s, and normally involve a γ (photon). The unstable particles listed in Table 32-2 decay either via the weak or the electro-

Particle Stability and Resonances

magnetic interaction.

Lifetime depends on which force is acting

Very short-lived particles are inferred from their decay products

Resonance

Uncertainty principle relates lifetime and mass width

Many particles have been found that decay via the strong interaction, with very short lifetimes, typically about 10^{-23} s, and these are not listed in Table 32-2. Their lifetimes are so short they do not travel far enough to be detected before decaying. The existence of such short-lived particles is inferred from their decay products. Consider the first such particle discovered (by Fermi), using a beam of π^+ directed through a hydrogen target (protons) with varying amounts of energy. The number of interactions (π ⁺ scattered) plotted versus the pion's kinetic energy is shown in Fig. $32-11$. The large number of interactions around 200 MeV led Fermi to conclude that the π^+ and proton combined momentarily to form a short-lived particle before coming apart again, or at least that they resonated together for a short time. Indeed, the large peak in Fig. $32-11$ resembles a resonance curve (see Figs. $11-18$ and $21-42$), and this new "particle"—now called the Δ —is referred to as a resonance. Hundreds of other resonances have been found, and are regarded as excited states of lighter mass particles such as the nucleon.

The width of a resonance—in Fig. 32-11 the width of the Δ peak is on the order of 100 MeV—is an interesting application of the uncertainty principle. If a particle lives only 10^{-23} s, then its mass (i.e., its rest energy) will be uncertain by an amount $\Delta E \approx h/(2\pi \Delta t) \approx (6.6 \times 10^{-34} \,\mathrm{J \cdot s})/(6)(10^{-23} \,\mathrm{s}) \approx 10^{-11} \,\mathrm{J} \approx$ 100 MeV, which is what is observed. Actually, the lifetimes of $\approx 10^{-23}$ s for such resonances are inferred by the reverse process: from the measured width being ≈ 100 MeV.

FIGURE 32-11 Number of π^+ particles scattered by a proton target as a function of the incident π^+ kinetic energy. The resonance shape represents the formation of a short-lived particle, the Δ , which has a charge in this case of $+2e(\Delta^{++})$.

32-8 Strange Particles? Charm? Maybe a New Model Is Needed!

In the early 1950s, the newly found particles K, Λ , and Σ were found to behave rather strangely in two ways. First, they were always produced in pairs. For example, the reaction

$$
\pi^- + \text{p} \to \text{K}^0 + \Lambda^0
$$

occurred with high probability, but the similar reaction π^- + p \rightarrow K⁰ + n was never observed to occur even though it did not violate any known conservation law. The second feature of these strange particles (as they came to be called) was that they were produced via the strong interaction (that is, at a high rate), but did not decay at a fast rate characteristic of the strong interaction (even though they decayed into strongly interacting particles).

To explain these observations, a new quantum number, strangeness, and a new conservation law, conservation of strangeness, were introduced. By assigning the strangeness numbers (S) indicated in Table 32–2, the production of strange particles in pairs was explained. Antiparticles were assigned opposite strangeness from their particles. For example, in the reaction π^- + p \rightarrow K⁰ + Λ^0 , the initial state has strangeness $S = 0 + 0 = 0$, and the final state has $S = +1 - 1 = 0$, so strangeness is conserved. But for π^- + p \rightarrow K⁰ + n, the initial state has $S = 0$ and the final state has $S = +1 + 0 = +1$, so strangeness would not be conserved; and this reaction is not observed.

To explain the decay of strange particles, it is assumed that strangeness is conserved in the strong interaction but is not conserved in the weak interaction. Thus, strange particles were forbidden by strangeness conservation to decay to nonstrange particles of lower mass via the strong interaction, but could decay by means of the weak interaction at the observed longer lifetimes of 10^{-10} to 10^{-8} s.

The conservation of strangeness was the first example of a *partially* conserved quantity. In this case, the quantity strangeness is conserved by strong interactions but not by weak.

CONCEPTUAL EXAMPLE 32-6 Guess the missing particle. Using the conservation laws for particle interactions, determine the possibilities for the missing particle in the reaction

$$
\pi^- + \mathbf{p} \to \mathbf{K}^0 + ?
$$

in addition to $K^0 + \Lambda^0$.

RESPONSE We write equations for the conserved numbers in this reaction, with B, L_e, S , and Q as unknowns whose determination will reveal what the possible particle might be:

The unknown product particle would have to have these characteristics:

 $B = +1$ $L_c = 0$ $Q = 0$ $S = -1$.

In addition to Λ^0 , a neutral sigma particle, Σ^0 , is also consistent with these numbers.

In the next Section we will discuss another partially conserved quantity which was given the name charm. The discovery in 1974 of a particle with charm helped solidify a new theory involving quarks, which we now discuss.

Strangeness and its conservation

Strangeness is conserved in strong interactions but not in weak

All particles, except the gauge bosons, are either leptons or hadrons. The principal difference between these two groups is that the hadrons interact via the strong interaction, whereas the leptons do not.

The six leptons (e⁻, μ ⁻, τ , ν_e , ν_{μ} , ν_{τ}) are considered to be truly elementary particles because they do not show any internal structure, and have no measurable size. (Attempts to determine the size of leptons have put an upper limit of about 10^{-18} m.)

There are hundreds of hadrons, on the other hand, and experiments indicate they do have an internal structure. In 1963, M. Gell-Mann and G. Zweig proposed that none of the hadrons, not even the proton and neutron, are truly elementary, but instead are made up of combinations of three, more fundamental, pointlike entities called, somewhat whimsically, quarks.[†] Today, the quark theory is well-accepted, and quarks are considered the truly elementary particles, like leptons. The three quarks originally proposed were labeled u, d, s, and have the names up, down, and strange. The theory today has six quarks, just as there are six leptons—based on a presumed symmetry in nature. The other three quarks are called *charmed*, *bottom*, and *top*. The names apply also to new properties of each (quantum numbers c, t, b) that distinguish the new quarks from the old quarks (see Table 32–3), and which (like strangeness) are conserved in strong, but not weak, interactions. All quarks have spin $\frac{1}{2}$ and an electric charge of either $+\frac{2}{3}e$ or $-\frac{1}{3}e$ (that is, a fraction of the previously thought smallest charge e). Antiquarks have opposite sign of electric charge Q , baryon number B , strangeness S , charm c , bottomness b , and topness t . Other properties of quarks are shown in Table 32–3.

 $Mesons = quark + an antiquark$ $Baryons = 3 quarks$

All hadrons are considered to be made up of combinations of quarks, and their properties are described by looking at their quark content. Mesons consist of a quark-antiquark pair. For example, a π^+ meson is a ud combination: note that for the ud pair, $Q = \frac{2}{3}e + \frac{1}{3}e = +1e$, $B = \frac{1}{3} - \frac{1}{3} = 0$, $S = 0 + 0 = 0$, as they must for a π^+ ; and a K⁺ = us, with $Q = +1$, $B = 0$, $S = +1$. Baryons, on the other hand, consist of three quarks. For example, a neutron is $n = ddu$, whereas an antiproton is $\bar{p} = \bar{u}\bar{u}\bar{d}$. See Fig. 32–12. Strange particles all contain an s or \bar{s} quark, whereas charmed particles contain a c or \bar{c} quark. A few of these hadrons are listed in Table 32-4.

After the quark theory was proposed, physicists began looking for these fractionally charged particles, but direct detection has not been successful. Current models suggest that quarks may be so tightly bound together that they may not ever exist singly in the free state. But observations of very high energy electrons scattered off protons suggest that protons are indeed made up of constituents.

[†]Gell-Mann chose the word from a phrase in James Joyce's Finnegans Wake.

Ouarks

Today, the truly elementary particles are considered to be the six quarks, the six leptons, and the gauge bosons that carry the fundamental forces. See Table 32-5, where the quarks and leptons are arranged in three "generations." Ordinary matter-atoms made of protons, neutrons, and electrons-is contained in the "first generation." The others are thought to have existed in the very early universe, but are seen by us today only at powerful accelerators or in cosmic rays. All of the hundreds of hadrons can be accounted for by combinations of the six quarks and six antiquarks.

The elementary particles are quarks, leptons, gauge bosons

[†]Note that the quarks and leptons are arranged into three generations each.

CONCEPTUAL EXAMPLE 32-7 Quark combinations. Find the baryon number, charge, and strangeness for the following quark combinations, and identify the hadron particle that is made up of these quark combinations: (a) udd, (b) u \overline{u} , (c) uss, (d) sdd, and (e) b \overline{u} .

RESPONSE We use Table 32-3 to get the properties of the quarks, then Table 32-2 or 32-4 to find the particle that has these properties. (a) udd has

$$
Q = +\frac{2}{3}e - \frac{1}{3}e - \frac{1}{3}e = 0,
$$

\n
$$
B = \frac{1}{3} + \frac{1}{3} + \frac{1}{3} = 1,
$$

\n
$$
S = 0 + 0 + 0 = 0,
$$

as well as $c = 0$, bottomness = 0, topness = 0. The only baryon ($B = +1$) that has $Q = 0$, $S = 0$, etc., is the neutron (Table 32-2). (b) $u\bar{u}$ has $Q = \frac{2}{3}e - \frac{2}{3}e = 0$, $B = 0$, and all other quantum numbers = 0. Sounds like a π^0 (dd also gives a π^0 , and we say a π^0 is $u\bar{u} + d\bar{d}$). (c) uss has $Q = 0$, $B = +1$, $S = -2$, others = 0. This is a Ξ^0 . (d) sdd has $Q = -1$, $B = +1$, $S = -1$, so must be a Σ^{-1} . (e) bu has $Q = -1$, $B = 0$, $S = 0$, $c = 0$, bottomness = -1, topness = 0. This must be a B^- meson (Table 32-4).

EXERCISE B What is the quark composition of a K⁻ meson?

32-10 The "Standard Model": Quantum Chromodynamics (QCD) and the Electroweak Theory

Not long after the quark theory was proposed, it was suggested that quarks have another property (or quality) called color, or "color charge" (analogous to electric charge). The distinction between the six quarks (u, d, s, c, b, t) was referred to as flavor. According to theory, each of the flavors of quark can have three colors, usually designated red, green, and blue. (These are the three primary colors which, when added together in equal amounts, as on a TV screen, produce white.) Note that the names "color" and "flavor" have nothing to do with our senses, but are purely whimsical—as are other names, such as charm, in this new field. (We did, however, "color" the quarks in Fig. 32-12.) The antiquarks are colored antired, antigreen, and antiblue. Baryons are made up of three quarks, one of each color. Mesons consist of a quark–antiquark pair of a particular color and its anticolor. Both baryons and mesons are thus colorless or white.

Fermions Bosons

Originally, the idea of quark color was proposed to preserve the Pauli exclusion principle (Section 28–7). Not all particles obey the exclusion principle. Those that do, such as electrons, protons, and neutrons, are called fermions. Those that don't are called **bosons**. These two categories are distinguished also in their spin (Section $28-6$): bosons have integer spin $(0, 1, 2, etc.)$ whereas fermions have half-integer spin, usually $\frac{1}{2}$ as for electrons and nucleons, but other fermions have spin $\frac{3}{2}$, $\frac{5}{2}$, etc. Matter is made up mainly of fermions, but the carriers of the forces $(\gamma, W, Z,$ and gluons) are all bosons. Quarks are fermions (they have spin $\frac{1}{2}$) and therefore should obey the exclusion principle. Yet for three particular baryons (uuu, ddd, and sss), all three quarks would have the same quantum numbers, and at least two quarks have their spin in the same direction (since there are only two choices, spin up $[m_s = +\frac{1}{2}]$ or spin down $[m_s = -\frac{1}{2}]$). This would seem to violate the exclusion principle; but if quarks have an additional quantum number (color), which is different for each quark, it would serve to distinguish them and allow the exclusion principle to hold. Although quark color, and the resulting threefold increase in the number of quarks, was originally an *ad hoc* idea, it also served to bring the theory into better agreement with experiment, such as predicting the correct lifetime of the π^0 meson. The idea of color soon became a central feature of the theory as determining the force binding quarks together in a hadron.

QCD

Gluons

Each quark is assumed to carry a color charge, analogous to electric charge, and the strong force between quarks is referred to as the color force. This theory of the strong force is called **quantum chromodynamics** (*chroma* = color in Greek), or **OCD**, to indicate that the force acts between color charges (and not between, say, electric charges). The strong force between two hadrons is considered to be a force between the quarks that make them up, as suggested in Fig. $32-13$. The particles that transmit the color force (analogous to photons for the EM force) are called **gluons** (a play on "glue"). They are included in Table 32–5. There are eight gluons, according to the theory, all massless and all have color charge.[†] Thus gluons have replaced mesons (Table $32-1$) as the particles responsible for the strong (color) force.

You might ask what would happen if we try to see a single quark with color by reaching deep inside a hadron and extracting a single quark. Quarks are so tightly bound to other quarks that extracting one would require a tremendous amount of energy, so much that it would be sufficient to create more quarks $(E = mc^2)$. Indeed, such experiments are done at modern particle colliders and all we get is more hadrons (quark-antiquark pairs, or triplets), not an isolated quark. This property of quarks, that they are always bound in groups that are colorless, is called confinement.

Confinement

⁷Compare to the EM interaction, where the photon has no electric charge. Because gluons have color charge, they could attract each other and form composite particles (photons cannot). Such "glueballs" are being searched for.

FIGURE 32-13 (a) The force between two quarks holding them together as part of a proton, for example, is carried by a gluon, which in this case involves a change in color. (b) Strong interaction $n + p \rightarrow n + p$ with the exchange of a charged π meson (+ or -, depending on whether it is considered moving to the left or to the right). (c) Quark representation of the same interaction $n + p \rightarrow n + p$. The blue coiled lines between quarks represent gluon exchanges holding the hadrons together.

The color force has the interesting property that, as two quarks approach each other very closely (equivalently, have high energy), the force between them becomes small. This aspect is referred to as asymptotic freedom.

The weak force, as we have seen, is thought to be mediated by the W^+ , $W^$ and Z^0 particles. It acts between the "weak charges" that each particle has. Each elementary particle can thus have electric charge, weak charge, color charge, and gravitational mass, although one or more of these could be zero. For example, all leptons have color charge of zero, so they do not interact via the strong force.

CONCEPTUAL EXAMPLE 32-8 Beta decay. Draw a Fevnman diagram. showing what happens in beta decay using quarks.

RESPONSE Beta decay is a result of the weak interaction, and the mediator is either a W^{\pm} or Z^{0} particle. What happens, in part, is that a neutron (udd quarks) decays into a proton (uud). Apparently a d quark (charge $-\frac{1}{3}e$) has turned into a u quark (charge $+\frac{2}{3}e$). Charge conservation means that a negatively charged particle, namely a W^- , was emitted by the d quark. Since an electron and an antineutrino appear in the final state, they must have come from the decay of the virtual W^- , as shown in Fig. 32–14.

To summarize, the standard model says that the truly elementary particles (Table 32–5) are the leptons, the quarks, and the gauge bosons (photon, W and Z, and the gluons). Some theories suggest there may be other bosons as well. The photon, leptons, W^+ , W^- , and Z^0 have all been observed in experiments. But so far only combinations of quarks (baryons and mesons) have been observed, and it seems likely that free quarks and gluons are unobservable.

One important aspect of new theoretical work is the attempt to find a unified basis for the different forces in nature. This was a long-held hope of Einstein, which he was never able to fulfill. A so-called gauge theory that unifies the weak and electromagnetic interactions was put forward in the 1960s by S. Weinberg, S. Glashow, and A. Salam. In this electroweak theory, the weak and electromagnetic forces are seen as two different manifestations of a single, more fundamental, electroweak interaction. The electroweak theory has had many successes, including the prediction of the W^{\pm} particles as carriers of the weak force, with masses of 81 \pm 2 GeV/ c^2 in excellent agreement with the measured values of 80.41 \pm 0.10 GeV/ c^2 (and similar accuracy for the Z⁰).

The combination of electroweak theory plus QCD for the strong interaction **Standard Model** is often referred to today as the **Standard Model**.

Leptons and the weak force

Unification

Electroweak theory

Higgs

 GUT

Theoreticians have wondered why the W and Z have large masses rather than being massless like the photon. Electroweak theory suggests an explanation by means of a new Higgs field and its particle, the Higgs boson, which interact with the W and Z to "slow them down." In being forced to go slower than the speed of light, they must acquire mass. The search for the Higgs boson will be a priority for experimental particle physicists when CERN's Large Hadron Collider (Section 32–1) starts running. So far, searches have excluded a Higgs lighter than 115 GeV/ c^2 . Yet it is expected to have a mass no larger than $200 \text{ GeV}/c^2$. We are narrowing in on it.

32-11 Grand Unified Theories

With the success of the unified electroweak theory, attempts are being made to incorporate it and OCD for the strong (color) force into a so-called grand unified theory (GUT). One type of such a grand unified theory of the electromagnetic, weak, and strong forces has been worked out in which there is only one class of particle—leptons and quarks belong to the same family and are able to change freely from one type to the other-and the three forces are different aspects of a single underlying force. The unity is predicted to occur, however, only on a scale of less than about 10^{-32} m corresponding to an extremely high energy of about 10^{16} GeV. If two elementary particles (leptons or quarks) approach each other to within this **unification scale**, the apparently fundamental distinction between them would not exist at this level, and a quark could readily change to a lepton, or vice versa. Baryon and lepton numbers would not be conserved. The weak, electromagnetic, and strong (color) force would blend to a force of a single strength.

Symmetry breaking

Unification of forces

What happens between the unification distance of 10^{-32} m and more normal (larger) distances is referred to as symmetry breaking. As an analogy, consider an atom in a crystal. Deep within the atom, there is much symmetry—in the innermost regions the electron cloud is spherically symmetric (Chapter 28). Farther out, this symmetry breaks down—the electron clouds are distributed preferentially along the lines (bonds) joining the atoms in the crystal. In a similar way, at 10^{-32} m the force between elementary particles is theorized to be a single force—it is symmetrical and does not single out one type of "charge" over another. But at larger distances, that symmetry is broken and we see three distinct forces. (In the "standard model" of electroweak interactions, Section 32–10, the symmetry breaking between the electromagnetic and the weak interactions occurs at about 10^{-18} m.)

FIGURE 32-15 Symmetry around a table. Example 32-9.

CONCEPTUAL EXAMPLE 32-9 Symmetry. The table in Fig. 32-15 has four identical place settings. Four people sit down to eat. Describe the symmetry of this table and what happens to it when someone starts the meal.

RESPONSE The table has several kinds of symmetry. It is symmetric to rotations of 90°: that is, the table will look the same if everyone moved one chair to the left or to the right. It is also north-south symmetric and east-west symmetric, so that swaps across the table don't affect the way the table looks. It also doesn't matter whether any person picks up the fork to the left of the plate or the fork to the right. But once that first person picks up either fork, the choice is set for all the rest at the table as well. The symmetry has been *broken*. The underlying symmetry is still there—the blue glasses could still be chosen either way—but some choice must get made and at that moment the symmetry of the diners is broken.

Proton decay?

Since unification occurs at such tiny distances and huge energies, the theory is difficult to test experimentally. But it is not completely impossible. One testable prediction is the idea that the proton might decay (via, for example, $p \rightarrow \pi^{0} + e^{+}$ and violate conservation of barvon number. This could happen if two quarks approached to within 10^{-31} m of each other. But it is very unlikely at normal temperature and energy, so the decay of a proton can only be an unlikely process. In the simplest form of GUT, the theoretical estimate of the proton lifetime for the decay mode $p \rightarrow \pi^0 + e^+$ is about 10³¹ yr, and this has just come within the realm of testability.[†] Proton decays have still not been seen, and experiments put the lower limit on the proton lifetime for the above mode to be about 10^{33} yr, somewhat greater than this prediction. This may seem a disappointment, but on the other hand, it presents a challenge. Indeed more complex GUTs are not affected by this result.

EXAMPLE 32-10 ESTIMATE Proton decay. An experiment uses 3300 tons of water waiting to see a proton decay of the type $p \rightarrow \pi^0 + e^+$. If the experiment is run for 4 years without detecting a decay, estimate the lower limit on the proton half-life.

APPROACH As with radioactive decay, the number of decays is proportional to the number of parent species (N) , the time interval (Δt) , and the decay constant (λ) which is related to the half-life T_1 by (see Eqs. 30–3 and 30–6):

$$
\Delta N = -\lambda N \, \Delta t = -\frac{\ln 2}{T_+} N \, \Delta t.
$$

SOLUTION Dealing only with magnitudes, we solve for T_1 :

$$
T_{\frac{1}{2}} = \frac{N}{\Delta N} \Delta t \ln 2.
$$

Thus for $\Delta N < 1$ over the four-year trial,

$$
T_{\frac{1}{2}} > N(4 \text{ yr})(0.693),
$$

where N is the number of protons in 3300 tons of water. To determine N , we note that each molecule of H₂O contains $(2 + 8 =)10$ protons. So one mole of water (18 g, 6×10^{23} molecules) contains $10 \times 6 \times 10^{23}$ protons in 18 g of water, or about 3×10^{26} protons per kilogram. One ton is 10^3 kg, so the chamber contains $(3.3 \times 10^6 \text{ kg})(3 \times 10^{26} \text{ protons/kg}) \approx 1 \times 10^{33} \text{ protons}.$ Then our very rough estimate for a lower limit on the proton half-life is $T_1 > (10^{33})(4 \text{ yr})(0.7) \approx 3 \times 10^{33} \text{ yr}.$

An interesting prediction of unified theories relates to cosmology (Chapter 33). It is thought that during the first 10^{-35} s after the theorized Big Bang that created the universe, the temperature was so extremely high that particles had energies corresponding to the unification scale. Baryon number would not have been conserved then, perhaps allowing an imbalance that might account for the observed predominance of matter $(B > 0)$ over antimatter $(B < 0)$ in the universe.

This last example is interesting, for it illustrates a deep connection between investigations at either end of the size scale: theories about the tiniest objects (elementary particles) have a strong bearing on the understanding of the universe on a large scale. We will look at this more in the next Chapter.

Connection with cosmology

[†]This is much larger than the age of the universe ($\approx 14 \times 10^9$ yr). But we don't have to wait 10³¹ yr to see. Instead we can wait for one decay among 10^{31} protons over a year (see Eqs. 30–3 and 30–6, $\Delta N = \lambda N \Delta t = 0.693N \Delta t/T_{\rm i}.$

32-12 Strings and Supersymmetry

Even more ambitious than grand unified theories are attempts to also incorporate gravity, and thus unify all four forces in nature into a single theory. (Such theories are sometimes referred to misleadingly as theories of everything.) There are consistent theories that attempt to unify all four forces called string **theories**, in which the elementary particles (Table $32-5$) are imagined not as points but as one-dimensional strings perhaps 10^{-35} m long.

String theory

Supersymmetry

A related idea is supersymmetry, which applied to strings is known as superstring theory. Supersymmetry predicts that interactions exist that would change fermions into bosons and vice versa, and that all known fermions have supersymmetric boson partners. Thus, for each quark we know (a fermion), there would be a *squark* (a *boson*) or "supersymmetric" quark. For every lepton there would be a *slepton*. Likewise, for every known boson (photons and gluons, for example), there would be a supersymmetric fermion (photinos and gluinos). Supersymmetry predicts also that a graviton, which transmits the gravity force, has a partner, the gravitino. Supersymmetric particles are sometimes called "SUSYs" for short, and may be a candidate for the "dark matter" of the universe (discussed in Chapter 33). But why hasn't this "missing part" of the universe ever been detected? The best guess is that supersymmetric particles might be heavier than their conventional counterparts, perhaps too heavy to have been produced in today's accelerators. Until a supersymmetric particle is found, and it may be possible at CERN's new LHC, supersymmetry is just an elegant guess.

The world of elementary particles is opening new vistas. What happens in the future is bound to be exciting.

Summary

Particle accelerators are used to accelerate charged particles, such as electrons and protons, to very high energy. Highenergy particles have short wavelength and so can be used to probe the structure of matter at very small distances in great detail. High kinetic energy also allows the creation of new particles through collision (via $E = mc^2$).

Cyclotrons and synchrotrons use a magnetic field to keep the particles in a circular path and accelerate them at intervals by high voltage. Linear accelerators accelerate particles along a line. Colliding beams allow higher interaction energy.

An antiparticle has the same mass as a particle but opposite charge. Certain other properties may also be opposite: for example, the antiproton has baryon number (nucleon number) opposite to that for the proton.

In all nuclear and particle reactions, the following conservation laws hold: momentum, angular momentum, mass-energy, electric charge, baryon number, and lepton numbers.

Certain particles have a property called strangeness, which is conserved by the strong force but not by the weak force. The properties charm, bottomness, and topness also are conserved by the strong force but not by the weak.

Just as the electromagnetic force can be said to be due to an exchange of photons, the strong nuclear force was first thought to be carried by *mesons* that have rest mass, but recent theory says the force is carried by massless gluons. The W and Z particles carry the weak force. These fundamental force carriers (photon, W and Z, gluons) are called gauge bosons.

Other particles can be classified as either leptons or hadrons. Leptons participate in the weak and electrically charged electromagnetic interactions. Hadrons, which today are considered to be made up of quarks, participate in the strong interaction as well. The hadrons can be classified as mesons, with baryon number zero, and baryons, with nonzero barvon number.

All particles, except for the photon, electron, neutrinos, and proton, decay with measurable half-lives varying from 10^{-25} s to 10^3 s. The half-life depends on which force is predominant. Weak decays usually have half-lives greater than about 10^{-13} s. Electromagnetic decays have half-lives on the order of 10^{-16} to 10^{-19} s. The shortest lived particles, called resonances, decay via the strong interaction and live typically for only about 10^{-23} s.

Today's standard model of elementary particles considers quarks as the basic building blocks of the hadrons. The six quark "flavors" are called up, down, strange, charmed, bottom, and top. It is expected that there are the same number of quarks as leptons (six of each), and that quarks and leptons are the truly elementary particles along with the gauge bosons $(\gamma, W, Z,$ gluons). Quarks are said to have color, and, according to quantum chromodynamics (QCD), the strong color force acts between their color charges and is transmitted by gluons. Electroweak theory views the weak and electromagnetic forces as two aspects of a single underlying interaction. QCD plus the electroweak theory are referred to as the Standard Model.

Grand unified theories of forces suggest that at very short distances (10^{-32} m) and very high energy, the weak, electromagnetic, and strong forces appear as a single force, and the fundamental difference between quarks and leptons disappears.
Questions

- 1. Give a reaction between two nucleons, similar to Eq. 32–4, that could produce a π^- .
- 2. If a proton is moving at very high speed, so that its kinetic energy is much greater than its rest energy (m_0c^2) , can it then decay via $p \rightarrow n + \pi^{+}$?
- 3. What would an "antiatom," made up of the antiparticles to the constituents of normal atoms, consist of? What might happen if *antimatter*, made of such antiatoms, came in contact with our normal world of matter?
- 4. What particle in a decay signals the electromagnetic interaction?
- 5. Does the presence of a neutrino among the decay products of a particle necessarily mean that the decay occurs via the weak interaction? Do all decays via the weak interaction produce a neutrino? Explain.
- 6. Why is it that a neutron decays via the weak interaction even though the neutron and one of its decay products (proton) are strongly interacting?
- 7. Which of the four interactions (strong, electromagnetic, weak, gravitational) does an electron take part in? A neutrino? A proton?
- 8. Check that charge and baryon number are conserved in each of the decays in Table 32-2.
- 9. Which of the particle decays in Table 32–2 occur via the electromagnetic interaction?
- 10. Which of the particle decays in Table 32-2 occur by the weak interaction?
- 11. By what interaction, and why, does Σ^{\pm} decay to Λ^{0} ? What about Σ^0 decaying to Λ^0 ?
- **12.** The Δ baryon has spin $\frac{3}{2}$, baryon number 1, and charge $Q = +2$, +1, 0, or -1. Why is there no charge state $Q = -2?$
- 13. Which of the particle decays in Table 32-4 occur via the electromagnetic interaction?
- 14. Which of the particle decays in Table 32-4 occur by the weak interaction?
- **15.** Quarks have spin $\frac{1}{2}$. How do you account for the fact that baryons have spin $\frac{1}{2}$ or $\frac{3}{2}$, and mesons have spin 0 or 1?
- 16. Suppose there were a kind of "neutrinolet" that was massless, had no color charge or electrical charge, and did not feel the weak force. Could you say that this particle even exists?
- 17. Is it possible for a particle to be both (a) a lepton and a baryon? (b) a baryon and a hadron? (c) a meson and a quark? (d) a hadron and a lepton? Explain.
- 18. Using the ideas of quantum chromodynamics, would it be possible to find particles made up of two quarks and no antiquarks? What about two quarks and two antiquarks?
- 19. Why do neutrons decay when they are free but not when they are inside the nucleus?
- **20.** Is the reaction $e^- + p \rightarrow n + \bar{\nu}_e$ possible? Explain.
- 21. Occasionally, the Λ will decay by the following reaction: $\Lambda^0 \rightarrow p^+ + e^- + \bar{\nu}_e$. Which of the four forces in nature is responsible for this decay? How do you know?

Problems

32-1 Particles and Accelerators

- 1. (I) What is the total energy of a proton whose kinetic energy is 6.35 GeV?
- 2. (I) Calculate the wavelength of 35-GeV electrons.
- 3. (I) What strength of magnetic field is used in a cyclotron in which protons make 2.8×10^7 revolutions per second?
- 4. (I) What is the time for one complete revolution for a very high-energy proton in the 1.0-km-radius Fermilab accelerator?
- 5. (I) If α particles are accelerated by the cyclotron of Example 32-2, what must be the frequency of the voltage applied to the dees?
- 6. (II) (a) If the cyclotron of Example $32-2$ accelerated α particles, what maximum energy could they attain? What would their speed be? (b) Repeat for deuterons $(^{2}_{1}H)$. (c) In each case, what frequency of voltage is required?
- 7. (II) Which is better for picking out details of the nucleus: 30-MeV alpha particles or 30-MeV protons? Compare each of their wavelengths with the size of a nucleon in a nucleus.
- 8. (II) The voltage across the dees of a cyclotron is 55 kV . How many revolutions do protons make to reach a kinetic energy of 25 MeV?
- 9. (II) What is the wavelength $(=$ maximum resolvable distance) of 7.0-TeV protons?
- $10.$ (II) A cyclotron with a radius of 1.0 m is to accelerate deuterons $(^{2}_{1}H)$ to an energy of 12 MeV. (a) What is the required magnetic field? (b) What frequency is needed for the voltage between the dees? (c) If the potential difference between the dees averages 22 kV, how many revolutions will the particles make before exiting? (d) How much time does it take for one deuteron to go from start to exit. (e) Estimate how far it travels during this time.
- 11. (II) The 4.25-km-radius tunnel that will be used to house the magnets for the Large Hadron Collider (LHC) calls for proton beams of energy 7.0 TeV. What magnetic field will be required?
- 12. (II) The 1.0-km radius Fermilab Tevatron takes about 20 seconds to bring the energies of the stored protons from 150 GeV to 1.0 TeV. The acceleration is done once per turn. Estimate the energy given to the protons on each turn. (You can assume that the speed of the protons is essentially c the whole time.)
- 13. (III) Show that the energy of a particle (charge e) in a synchrotron, in the relativistic limit ($v \approx c$), is given by E (in eV) = Brc, where B is magnetic field strength and r the radius of the orbit (SI units).
- 14. (III) What magnetic field intensity is needed at the 1.0-km-radius Fermilab synchrotron for 1.0-TeV protons?

32-2 to 32-6 Particle Interactions, Particle Exchange

15. (I) How much energy is released in the decay

 $\pi^+ \to \mu^+ + \nu_{\mu}$?

See Table 32-2.

- 16. (I) About how much energy is released when a Λ^0 decays to $n + \pi^{0}$? (See Table 32–2.)
- 17. (I) How much energy is required to produce a neutronantineutron pair?
- **18.** (I) Estimate the range of the strong force if the mediating particle were the kaon instead of the pion.
- 19. (II) Two protons are heading toward each other with equal speeds. What minimum kinetic energy must each have if a π^0 meson is to be created in the process? (See Table 32-2.)
- 20. (II) What minimum kinetic energy must two neutrons each have if they are traveling at the same speed toward each other, collide, and produce a K^+K^- pair in addition to themselves? (See Table 32–2.)
- 21. (II) Estimate the range of the weak force using Eq. $32-3$, given the masses of the W and Z particles as about 80 to 90 GeV/ c^2 .
- 22. (II) What are the wavelengths of the two photons produced when a proton and antiproton at rest annihilate?
- 23. (II) The Λ cannot decay by the following reactions. What conservation law is violated in each of the reactions?
	- (a) $\Lambda^0 \rightarrow n + \pi^+$
	- (b) $\Lambda^0 \rightarrow p + K^-$
	- $(c) \ \Lambda^0 \rightarrow \pi^+ + \pi$
- **24.** (II) For the decay $\Lambda^0 \rightarrow p + \pi^-$, calculate (a) the *Q*-value (energy released), and (b) the kinetic energy of the p and π^- , assuming the Λ^0 decays from rest. (Use relativistic formulas.)
- $25.$ (II) (*a*) Show, by conserving momentum and energy, that it is impossible for an isolated electron to radiate only a single photon. (b) With this result in mind, how can you defend the photon exchange diagram in Fig. 32-7?
- 26. (II) What would be the wavelengths of the two photons produced when an electron and a positron, each with 420 keV of kinetic energy, annihilate head on?
- 27. (II) In the rare decay $\pi^+ \to e^+ + \nu_e$, what is the kinetic energy of the positron? Assume the π^+ decays from rest.
- 28. (II) Which of the following reactions and decays are possible? For those forbidden, explain what laws are violated.
	- (a) π^- + p \to n + η^0 (b) $\pi^+ + p \to n + \pi^0$
	- (c) $\pi^+ + p \to p + e^+$
	- (d) $p \rightarrow e^+ + \nu_e$
	- (e) $\mu^+ \to e^+ + \bar{\nu}_{\mu}$
	- (f) $p \rightarrow n + e^{+} + \nu_e$
- 29. (II) Calculate the kinetic energy of each of the two products in the decay $\Xi^- \to \Lambda^0 + \pi^-$. Assume the Ξ^- decays from rest.
- 30. (III) Could a π^+ meson be produced if a 100-MeV proton struck a proton at rest? What minimum kinetic energy must the incoming proton have?
- 31. (III) Calculate the maximum kinetic energy of the electron in the decay $\mu^- \rightarrow e^- + \bar{\nu}_e + \nu_\mu$. [*Hint*: in what direction do the two neutrinos move relative to the electron in order to give the latter the maximum kinetic energy? Both energy and momentum are conserved; use relativistic formulas.]

32-7 to 32-11 Resonances, Standard Model, Quarks, **QCD, GUT**

- $32.$ (I) Use Fig. 32-11 to estimate the energy width and then the lifetime of the Δ resonance using the uncertainty principle.
- 33. (I) The measured width of the J/ψ meson is 88 keV. Estimate its lifetime.
- 34. (I) The measured width of the ψ (3685) meson is 277 keV. Estimate its lifetime.
- 35. (I) What is the energy width (or uncertainty) of (a) η^0 , and (b) Σ^0 ? See Table 32-2.
- 36. (I) The B⁻ meson is a bu quark combination. (a) Show that this is consistent for all quantum numbers. (b) What are the quark combinations for B^+ , B^0 , $\overline{B}{}^0$?
- 37. (II) Which of the following decays are possible? For those that are forbidden, explain which laws are violated.
	- (a) $\Xi^0 \rightarrow \Sigma^+ + \pi^-$ (b) $\Omega^- \rightarrow \Sigma^0 + \pi^- + \nu$ (c) $\Sigma^0 \rightarrow \Lambda^0 + \gamma + \gamma$
- 38. (II) What are the quark combinations that can form (a) a neutron, (b) an antineutron, (c) a Λ^0 , (d) a $\overline{\Sigma}{}^0$?
- 39. (II) What particles do the following quark combinations produce: (a) uud, (b) $\overline{u}\overline{u}\overline{s}$, (c) $\overline{u}s$, (d) $d\overline{u}$, (e) $\overline{c}s$?
- 40. (II) What is the quark combination needed to produce a D^0 meson $(Q = B = S = 0, c = +1)$?
- 41. (II) The D_S⁺ meson has $S = c = +1$, $B = 0$. What quark combination would produce it?
- 42. (II) Draw a possible Feynman diagram using quarks (as in Fig. 32–13c) for the reaction π^- + p $\rightarrow \pi^0$ + n.
- 43. (II) Draw a Feynman diagram for the reaction $n + \nu_{\mu} \rightarrow p + \mu^{-}$.

General Problems

- 44. What is the total energy of a proton whose kinetic energy is 25 GeV? What is its wavelength?
- 45. Assume there are 5.0×10^{13} protons at 1.0 TeV stored in the 1.0-km-radius ring of the Tevatron. (a) How much current (amperes) is carried by this beam? (b) How fast would a 1500-kg car have to move to carry the same kinetic energy as this beam?
- 46. Protons are injected into the 1.0-km-radius Fermilab Tevatron with an energy of 150 GeV. If they are accelerated by 2.5 MV each revolution, how far do they travel and approximately how long does it take for them to reach 1.0 TeV?
- 47. (a) How much energy is released when an electron and a positron annihilate each other? (b) How much energy is released when a proton and an antiproton annihilate each other? (All particles $KE \approx 0$.)
- 48. Which of the following reactions are possible, and by what interaction could they occur? For those forbidden, explain why.

(a)
$$
\pi^-
$$
 + p \rightarrow K⁺ + Σ^-
\n(b) π^+ + p \rightarrow K⁺ + Σ^+
\n(c) π^- + p \rightarrow Λ^0 + K⁰ + π^0
\n(d) π^+ + p \rightarrow Σ^0 + π^0
\n(e) π^- + p \rightarrow p + e⁻ + $\bar{\nu}_e$

- 49. Which of the following reactions are possible, and by what interaction could they occur? For those forbidden, explain why.
	- (a) π^- + p \to K⁰ + p + π^0 (b) K^- + $p \rightarrow \Lambda^0$ + π^0 (c) $K^+ + n \rightarrow \Sigma^+ + \pi^0 + \gamma$ (d) $K^+ \to \pi^0 + \pi^0 + \pi^+$ (e) $\pi^+ \to e^+ + \nu_e$
- 50. One decay mode for a π^+ is $\pi^+ \to \mu^+ + \nu_\mu$. What would be the equivalent decay for a π^{-} ? Check conservation rules.
- 51. Symmetry breaking occurs in the electroweak theory at about 10^{-18} m. Show that this corresponds to an energy that is on the order of the mass of the W^{\pm} .
- 52. The mass of a π^0 can be measured by observing the reaction π^- + p $\rightarrow \pi^0$ + n at very low incident π^- kinetic energy (assume it is zero). The neutron is observed to be emitted with a kinetic energy of 0.60 MeV. Use conservation of energy and momentum to determine the π^0 mass.
- 53. Calculate the *Q*-value for each of the reactions, Eq. $32-4$, for producing a pion.
- **54.** Calculate the *Q*-value for the reaction π^- + p $\rightarrow \Lambda^0$ + K⁰. when negative pions strike stationary protons. Estimate the minimum pion kinetic energy needed to produce this reaction. [*Hint*: assume Λ^0 and K^0 move off with the same velocity.]
- 55. How many fundamental fermions are there in a water molecule?
- 56. A proton and an antiproton annihilate each other at rest and produce two pions, π^- and π^+ . What is the kinetic energy of each pion?
- 57. (a) Show that the so-called unification distance of 10^{-32} m in grand unified theory is equivalent to an energy of about 10^{16} GeV. Use the uncertainty principle, and also de Broglie's wavelength formula, and explain how they apply. (b) Calculate the temperature corresponding to 10^{16} GeV.
- 58. For the reaction $p + p \rightarrow 3p + \bar{p}$, where one of the initial protons is at rest, use relativistic formulas to show that the threshold energy is $6m_p c^2$, equal to three times the magnitude of the Q-value of the reaction, where m_p is the proton mass. [*Hint*: assume all final particles have the same velocity.]
- 59. The lifetimes listed in Table 32–2 are in terms of *proper* time, measured in a reference frame where the particle is at rest. If a tau lepton is created with a kinetic energy of 450 MeV, how long would its track be as measured in the lab, on average, ignoring any collisions?
- 60. Identify the missing particle in the following reactions.

(a)
$$
p + p \rightarrow p + n + \pi^+ + \cdots
$$

$$
(b) p + ? \rightarrow n + \mu^+
$$

61. Use the quark model to describe the reaction

$$
\bar{p} + n \rightarrow \pi^- + \pi^0.
$$

62. What fraction of the speed of light c is the speed of a 7.0-TeV proton?

Answers to Exercises

A: 1.24×10^{-18} m.

 $B: s\overline{u}$.

This map of the entire sky (WMAP) is color-coded to represent slight temperature variations in the almost perfectly uniform 2.7-kelvin microwave background radiation that reaches us from all directions in the sky. Produced in 2003, it is providing detailed information on the origins of our universe and its structures. The red stripe across the middle is our own Galaxy, the Milky Way, showing up in the foreground. (It has been chosen as the "equator" for this projection of the full sky.)

To discuss the nature of the universe as we understand it today, we examine the latest theories on how stars and galaxies form and evolve, including the role of nucleosynthesis. We briefly discuss Einstein's general theory of relativity, which deals with gravity and curvature of space. We take a thorough look at the evidence for the expansion of

Astrophysics and Cosmology

n the previous Chapter, we studied the tiniest objects in the universe—the elementary particles. Now we leap to the largest—stars and galaxies. These two extreme realms, elementary particles and the cosmos, are among the most intriguing and exciting subjects in science. And, surprisingly, these two extreme realms are related in a fundamental way, as already hinted in Chapter 32.

Use of the techniques and ideas of physics to study the heavens is often referred to as **astrophysics**. Central to our present theoretical understanding of the universe (or cosmos) is Einstein's general theory of relativity and the modern theory of gravitation. Many other aspects of physics are involved, from electromagnetism and thermodynamics to atomic and nuclear physics as well as elementary particles. General Relativity serves also as the foundation for modern cosmology, which is the study of the universe as a whole. Cosmology deals especially with the search for a theoretical framework to understand the observed universe, its origin, and its future. The questions posed by cosmology are profound and difficult; the possible answers are often unimaginable. They are questions like "Has the universe always existed, or did it have a beginning in

CHAPTER

time?" Either alternative is difficult to imagine: time going back indefinitely into the past, or an actual moment when the universe began (but, then, what was there before?). And what about the size of the universe? Is it infinite in size? It is hard to imagine infinity. Or is it finite in size? This is also hard to imagine, for if the universe is finite, it does not make sense to ask what is beyond it, because the universe is all there is.

In the last few years, so much progress has occurred in astrophysics and cosmology that many scientists are calling recent work a "Golden Age" for cosmology. Our survey will be qualitative, but we will nonetheless touch on the major ideas. We begin with a look at what can be seen beyond the Earth.

33-1 Stars and Galaxies

According to the ancients, the stars, except for the few that seemed to move (the planets), were fixed on a sphere beyond the last planet. The universe was neatly self-contained, and we on Earth were at or near its center. But in the centuries following Galileo's first telescopic observations of the heavens in 1610, our view of the universe has changed dramatically. We no longer place ourselves at the center, and we view the universe as vastly larger. The distances involved are so great that we specify them in terms of the time it takes light to travel the given distance: for example, 1 light-second = $(3.0 \times 10^8 \text{ m/s})(1.0 \text{ s}) = 3.0 \times 10^8 \text{ m} = 300,000 \text{ km}$; 1 light-minute = 18×10^6 km; and 1 light-year (ly) is

$$
1 \text{ ly} = (2.998 \times 10^8 \text{ m/s})(3.156 \times 10^7 \text{ s/yr})
$$

= 9.46 × 10¹⁵ m ≈ 10¹³ km.

For specifying distances to the Sun and Moon, we usually use meters or kilometers, but we could specify them in terms of light. The Earth–Moon distance is 384,000 km, which is 1.28 light-seconds. The Earth–Sun distance is 1.50×10^{11} m, or 150,000,000 km; this is equal to 8.3 light-minutes. Far out in our solar system, the ninth planet, Pluto, is about 6×10^9 km from the Sun, or 6×10^{-4} ly. The nearest star to us, other than the Sun, is Proxima Centauri, about 4.3 ly away. (Note that the nearest star is about 10,000 times farther from us than the outer reaches of our solar system.)

On a clear moonless night, thousands of stars of varying degrees of brightness can be seen, as well as the long cloudy stripe known as the Milky Way (Fig. 33-1). Galileo first observed, with his telescope, that the Milky Way is comprised of countless individual stars. A century and a half later (about 1750), Thomas Wright suggested that the Milky Way was a flat disc of stars extending to great distances in a plane, which we call the **Galaxy** (Greek for "milky way").

FIGURE 33-1 A section of the Milky Way. The thin line is the trail of an artificial Earth satellite.

Light-year (unit)

FIGURE 33-2 Our Galaxy, as it would appear from the outside: (a) "edge view," in the plane of the disc; (b) "top view," looking down on the disc. (If only we could see it like this—from the outside!) (c) Infrared photograph of the inner reaches of the Milky Way, showing the central bulge of our Galaxy. This very wide angle photo extends over 180° of sky, and to be viewed properly it should be wrapped in a semicircle with your eyes at the center. The white dots are nearby stars.

 (c)

Our Galaxy has a diameter of almost 100,000 light-years and a thickness of roughly 2000 ly. It has a bulging central "nucleus" and spiral arms (Fig. 33–2). Our Sun, which seems to be just another star, is located about halfway from the galactic center to the edge, some 26,000 ly from the center. Our Galaxy contains roughly 100 billion (10^{11}) stars. The Sun orbits the galactic center approximately once every 250 million years or so, so its speed is about 200 km/s relative to the center of the Galaxy. The total mass of all the stars in our Galaxy is estimated to be about 3×10^{41} kg, which is ordinary matter. In addition, there is strong evidence that our Galaxy is surrounded by an invisible "halo" of "dark matter," which we discuss in Section 33-8.

EXAMPLE 33-1 ESTIMATE Our Galaxy's mass. Estimate the total mass of our Galaxy using the orbital data of the Sun (including our solar system) about the center of the Galaxy. Assume that most of the mass of the Galaxy is concentrated near the center of the Galaxy.

APPROACH We assume that the Sun and the solar system (total mass m) move in a circular orbit about the center of the Galaxy (total mass M), and that the mass M can be considered as being located at the center of the Galaxy. We then apply Newton's second law, $F = ma$, with a being the centripetal acceleration, $a = v^2/r$, and F being the universal law of gravitation (Chapter 5).

SOLUTION Our Sun and solar system orbit the center of the Galaxy, according to the best measurements as mentioned above, with a speed of about $v = 200 \text{ km/s}$ at a distance from the Galaxy center of about $r = 26,000$ ly. We use Newton's second law:

$$
F = ma
$$

$$
G\frac{Mm}{r^2} = m\frac{v^2}{r}
$$

where M is the mass of the Galaxy and m is the mass of our Sun and solar system. Solving this, we find

$$
M = \frac{rv^2}{G} \approx \frac{(26,000 \text{ ly})(10^{16} \text{ m/ly})(2 \times 10^5 \text{ m/s})^2}{6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2} \approx 2 \times 10^{41} \text{ kg}.
$$

NOTE In terms of *numbers* of stars, if they are like our Sun ($m = 2.0 \times 10^{30}$ kg), there would be about $(2 \times 10^{41} \text{ kg})/(2 \times 10^{30} \text{ kg}) \approx 10^{11} \text{ or about } 100 \text{ billion stars.}$

In addition to stars both within and outside the Milky Way, we can see by telescope many faint cloudy patches in the sky which were all referred to once as "nebulae" (Latin for "clouds"). A few of these, such as those in the constellations Andromeda and Orion, can actually be discerned with the naked eve on a clear night. Some are star clusters (Fig. 33-3), groups of stars that are so numerous they appear to be a cloud. Others are glowing clouds of gas or dust (Fig. 33–4), and it is for these that we now mainly reserve the word **nebula**. Most fascinating are those that belong to a third category: they often have fairly regular elliptical shapes and seem to be a great distance beyond our Galaxy. Immanuel Kant (about 1755) seems to have been the first to suggest that these latter might be circular discs, but appear elliptical because we see them at an angle, and are faint because they are so distant. At first it was not universally accepted that these objects were extragalactic—that is, outside our Galaxy. The very large telescopes constructed in the twentieth century revealed that individual stars could be resolved within these extragalactic objects and that many contain spiral arms. Edwin Hubble (1889–1953) did much of this observational work in the 1920s using the 2.5-m (100-inch) telescope^{\dagger} on Mt. Wilson near Los Angeles, California, then the world's largest. Hubble demonstrated that these objects were indeed extragalactic because of their great distances. The distance to our nearest large galaxy,^{\ddagger} Andromeda, is over 2 million light-years, a distance 20 times greater than the diameter of our Galaxy. It seemed logical that these nebulae must be galaxies similar to ours. (Note that it is usual to capitalize the word "galaxy" only when it refers to our own.) Today it is thought there are roughly 40×10^9 galaxies in the observable universe—that is, roughly as many galaxies as there are stars in a galaxy. See Fig. 33-5.

Many galaxies tend to be grouped in galaxy clusters held together by their mutual gravitational attraction. There may be anywhere from a few to many thousands

 $\frac{1}{2}$ = 100 inches) refers to the diameter of the curved objective mirror. The bigger the mirror, the more light it collects (greater intensity) and the less diffraction there is (better resolution), so more and fainter stars can be seen. See Chapter 25. Until recently, photographic films or plates were used to take long time exposures. Now large solid-state CCD sensors (Section 25-1) are available containing 100 million pixels (compared to 5 or 6 megapixels in a good-quality digital camera).

[‡]The *Magellanic clouds* are much closer than Andromeda, but are small and are usually considered small satellite galaxies of our own Galaxy.

FIGURE 33-5 Photographs of galaxies. (a) Spiral galaxy in the constellation Hydra. (b) Two galaxies: the larger and more dramatic one is known as the Whirlpool galaxy. (c) A false-color infrared image of the same galaxies as in (b), here showing the arms of the spiral as being more regular than in the visible light photo (b); the different colors correspond to different light intensities. Visible light is scattered and absorbed by interstellar dust much more than infrared is, so the latter gives us a clearer image.

FIGURE 33-3 This globular star cluster is located in the constellation Hercules.

FIGURE 33-4 This gaseous nebula, found in the constellation Carina, is about 9000 light-years from us.

TABLE 33-1 Heavenly Distances

of galaxies in each cluster. Furthermore, clusters themselves seem to be organized into even larger aggregates: clusters of clusters of galaxies, or superclusters. The farthest detectable galaxies are on the order of 10^{10} ly distant. See Table 33-1.

CONCEPTUAL EXAMPLE 33-2 Looking back in time. Astronomers often think of their telescopes as time machines, looking back toward the origin of the universe. How far back do they look?

RESPONSE The distance in light-years measures precisely how long in years the light has been traveling to reach us, so Table 33-1 tells us also how far back in time we are looking. For example, if we saw Proxima Centauri explode into a supernova today, then the event would have really occurred 4.3 years ago. The most distant galaxies, 10^{10} ly away, emitted the light we see now 10^{10} years ago; so what we see was how they were then, 10^{10} yr ago, close to the beginning of the universe.

EXERCISE A Suppose we could place a huge mirror 1 light-year away from us. What would we see in this mirror if it is facing us on Earth? When did it take place? (This might be called a "time machine.")

Besides the usual stars, clusters of stars, galaxies, and clusters and superclusters of galaxies, the universe contains a number of other interesting objects. Among these are stars known as red giants, white dwarfs, neutron stars, exploding stars called *novae* and *supernovae*, and *black holes* (very probably) whose gravity is so strong even light can not escape them. In addition, there is electromagnetic radiation that reaches the Earth but does not emanate from the bright pointlike objects we call stars: particularly important is the microwave background radiation that arrives nearly uniformly from all directions in the universe. We will discuss all these phenomena.

Quasar (QSO)

Finally, there are "active galactic nuclei" (AGN), which are very luminous pointlike sources of light in the centers of distant galaxies. The most dramatic examples of AGN are quasars ("quasistellar objects" or QSOs), which are so luminous that the surrounding starlight of the galaxy is drowned out. Their luminosity is thought to come from matter starting to fall into a giant black hole at a galaxy's center.

33-2 Stellar Evolution: The Birth and Death of Stars

The stars appear unchanging. Night after night the heavens reveal no significant variations. Indeed, on a human time scale, the vast majority of stars change very little (except for novae, supernovae, and certain variable stars). Although stars *seem* fixed in relation to each other, many move sufficiently for the motion to be detected. Speeds of stars relative to neighboring stars can be hundreds of km/s, but at their great distance from us, this motion is detectable only by careful measurement. Furthermore, there is a great range of brightness among stars. The differences in brightness are due to differences in the amount of light stars emit as well as to their different distances from us.

Luminosity and Brightness of Stars

A useful parameter for a star or galaxy is its luminosity (or "absolute luminosity"), L , by which we mean the total power radiated in watts. Also important is the apparent brightness, *l*, defined as the power crossing unit area at the Earth perpendicular to the path of the light. Given that energy is conserved, and ignoring any absorption in space, the total emitted power L when it reaches a distance d from the star will be spread over a sphere of surface area $4\pi d^2$. If d is the distance from the star to the Earth, then L must be equal to $4\pi d^2$ times l (power per unit area at Earth). That is,

$$
l = \frac{L}{4\pi d^2}.\tag{33-1}
$$

EXAMPLE 33-3 Apparent brightness. Suppose a particular star has absolute luminosity equal to that of the Sun but is 10 ly away from Earth. By what factor will it appear dimmer than the Sun?

APPROACH The luminosity L is the same for both stars, so the apparent brightness depends only on their relative distances. We use the inverse square law as stated in Eq. 33–1 to determine the relative brightness.

SOLUTION Using Eq. 33-1, we find that the star appears dimmer by a factor

 \sim \sim

$$
\frac{l_{\text{star}}}{l_{\text{sun}}} = \frac{d_{\text{sun}}^2}{d_{\text{star}}^2} = \frac{(1.5 \times 10^8 \text{ km})^2}{(10 \text{ ly})^2 (10^{13} \text{ km/ly})^2} \approx 2 \times 10^{-12}.
$$

Careful study of nearby stars has shown that the absolute luminosity for most stars depends on the mass:[†] the more massive the star, the greater its luminosity. Another important parameter of a star is its surface temperature, which can be determined from the spectrum of electromagnetic frequencies it emits, just as for a blackbody (Section 27-2). As we saw in Chapter 27, as the temperature of a body increases, the spectrum shifts from predominantly lower frequencies (and longer wavelengths, such as red) to higher frequencies (and shorter wavelengths such as blue). Quantitatively, the relation is given by Wien's law (Eq. $27-2$): the peak wavelength λ_p in the spectrum of light emitted by a blackbody (and stars are fairly good approximations to blackbodies) is inversely proportional to its kelvin temperature T; that is, $\lambda_p T = 2.90 \times 10^{-3} \text{ m} \cdot \text{K}$. The surface temperatures of stars typically range from about 3500 K (reddish) to perhaps 50,000 K (UV).

EXAMPLE 33-4 Determining star temperature and star size. Suppose that the distances from Earth to two nearby stars can be reasonably estimated, and that their measured apparent brightnesses suggest the two stars have about the same absolute luminosity, L. The spectrum of one of the stars peaks at about 700 nm (so it is reddish). The spectrum of the other peaks at about 350 nm (bluish). Use Wien's law (Eq. 27-2) and the Stefan-Boltzmann equation (Section 14–8) to determine (a) the surface temperature of each star, and (b) how much larger one star is than the other.

APPROACH We determine the surface temperature T for each star using Wien's law and each star's peak wavelength. Then, using the Stefan-Boltzmann equation (power output or luminosity $\propto AT^4$), we can find the surface area ratio and relative sizes of the two stars.

SOLUTION (a) Wien's law (Eq. 27-2) states that $\lambda_p T = 2.90 \times 10^{-3} \text{ m} \cdot \text{K}$. So the temperature of the reddish star is

$$
T_{\rm r} = \frac{2.90 \times 10^{-3} \,\mathrm{m} \cdot \mathrm{K}}{700 \times 10^{-9} \,\mathrm{m}} = 4140 \,\mathrm{K}.
$$

The temperature of the bluish star will be double this since its peak wavelength is half (350 nm vs. 700 nm); just to check:

$$
T_{\rm b} = \frac{2.90 \times 10^{-3} \,\mathrm{m} \cdot \mathrm{K}}{350 \times 10^{-9} \,\mathrm{m}} = 8280 \,\mathrm{K}.
$$

 (b) The Stefan-Boltzmann equation, which we discussed in Chapter 14 (see Eq. 14-5), states that the power radiated per unit area of surface from a body is proportional to the fourth power of the kelvin temperature, $T⁴$. Now the temperature of the bluish star is double that of the reddish star, so the bluish one must radiate $(2^4) = 16$ times as much energy per unit area. But we are given that they have the same luminosity (the same total power output); so the surface area of the blue star must be $\frac{1}{16}$ that of the red one. Since the surface area of a sphere is $4\pi r^2$, we conclude that the radius of the reddish star is $\sqrt{16}$ = 4 times larger than the radius of the bluish star (or $4^3 = 64$ times the volume). Luminosity increases with star's mass

^{*}Applies to "main-sequence" stars (see next page). The mass of a star can be determined by observing its gravitational effects. Many stars are part of a cluster, the simplest being a binary star in which two stars orbit around each other, allowing their masses to be determined using rotational mechanics.

H-R Diagram

 $H-R$ diagram

Main-sequence stars

Red giants White dwarfs An important astronomical discovery, made around 1900, was that for most stars, the color is related to the absolute luminosity and therefore to the mass. A useful way to present this relationship is by the so-called Hertzsprung–Russell $(H-R)$ diagram. On the H-R diagram, the horizontal axis shows the temperature T whereas the vertical axis is the luminosity L ; each star is represented by a point on the diagram, Fig. 33–6. Most stars fall along the diagonal band termed the main sequence. Starting at the lower right we find the coolest stars, reddish in color; they are the least luminous and therefore of low mass. Farther up toward the left we find hotter and more luminous stars that are whitish, like our Sun. Still farther up we find still more massive and more luminous stars, bluish in color. Stars that fall on this diagonal band are called *main-sequence stars*. There are also stars that fall outside the main sequence. Above and to the right we find extremely large stars, with high luminosities but with low (reddish) color temperature: these are called **red giants**. At the lower left, there are a few stars of low luminosity but with high temperature: these are the white dwarfs.

EXAMPLE 33-5 ESTIMATE Distance to a star using H-R and color. Suppose that detailed study of a certain star suggests that it most likely fits on the main sequence of an H-R diagram. Its measured apparent brightness is $l = 1.0 \times 10^{-12} \,\mathrm{W/m^2}$, and the peak wavelength of its spectrum is $\lambda_{P} \approx 600$ nm. Estimate its distance from us.

APPROACH We find the temperature using Wien's law, Eq. $27-2$. The absolute luminosity is estimated for a main sequence star on the H-R diagram of Fig. $33-6$, and then the distance is found using Eq. $33-1$.

SOLUTION The star's temperature, from Wien's law (Eq. 27-2), is

$$
T \approx \frac{2.90 \times 10^{-3} \,\mathrm{m} \cdot \mathrm{K}}{600 \times 10^{-9} \,\mathrm{m}} \approx 4800 \,\mathrm{K}
$$

A star on the main sequence of an H-R diagram at this temperature has absolute luminosity of about $L \approx 1 \times 10^{26}$ W, read off of Fig. 33–6. Then, from Eq. 33–1,

$$
d = \sqrt{\frac{L}{4\pi l}} \approx \sqrt{\frac{1 \times 10^{26} \,\mathrm{W}}{4(3.14)(1.0 \times 10^{-12} \,\mathrm{W/m^2})}} \approx 3 \times 10^{18} \,\mathrm{m}.
$$

Its distance from us in light-years is

$$
d = \frac{3 \times 10^{18} \,\mathrm{m}}{10^{16} \,\mathrm{m/ly}} \approx 300 \,\mathrm{ly}
$$

EXERCISE B Estimate the distance to a 6000 K star with an apparent brightness of 2.0×10^{-12} W/m².

Stellar Evolution: Nucleosynthesis

Why are there different types of stars, such as red giants and white dwarfs, as well as main-sequence stars? Were they all born this way, in the beginning? Or might each different type represent a different age in the life cycle of a star? Astronomers and astrophysicists today believe the latter is the case. Note, however, that we cannot actually follow any but the tiniest part of the life cycle of any given star since they live for ages vastly greater than ours, on the order of millions or billions of years. Nonetheless, let us follow the process of stellar evolution from the birth to the death of a star, as astrophysicists have theoretically reconstructed it today.

Stars are born, it is believed, when gaseous clouds (mostly hydrogen) contract due to the pull of gravity. A huge gas cloud might fragment into numerous contracting masses, each mass centered in an area where the density was only slightly greater than that at nearby points. Once such "globules" formed, gravity would cause each to contract in toward its center of mass. As the particles of such a *protostar* accelerate inward, their kinetic energy increases. When the kinetic energy is sufficiently high, the Coulomb repulsion between the positive charges is not strong enough to keep the hydrogen nuclei apart, and nuclear fusion can take place. In a star like our Sun, the "burning" of hydrogen[†] (that is, fusion) occurs via the *proton–proton* cycle (Section 31–3, Eqs. 31–6), in which four protons fuse to form a ${}_{2}^{4}$ He nucleus with the release of γ rays, positrons, and neutrinos: $4\overline{H} \rightarrow \overline{2}He + 2e^+ + 2\gamma$. These reactions require a temperature of about $10⁷$ K, corresponding to an average kinetic energy (kT) of about 1 keV (Eq. 13–8). In more massive stars, the carbon cycle produces the same net effect: Four ¹H produce a ⁴He—see Section $31-3$. The fusion reactions take place primarily in the core of a star, where T is sufficiently high. (The surface temperature is, of course, much lower-on the order of a few thousand kelvins.) The tremendous release of energy in these fusion reactions produces an outward pressure sufficient to halt the inward gravitational contraction; and our protostar, now really a young star, stabilizes on the main sequence. Exactly where the star falls along the main sequence depends on its mass. The more massive the star, the farther up (and to the left) it falls on the $H-R$ diagram of Fig. 33–6. To reach the main sequence requires perhaps 30 million years, if it is a star like our Sun, and it is expected to remain there^{\ddagger} about 10 billion years (10¹⁰ yr). Although most stars are billions of years old, there is evidence that stars are actually being born at this moment.

As hydrogen fuses to form helium, the helium that is formed is denser and tends to accumulate in the central core where it was formed. As the core of helium grows, hydrogen continues to fuse in a shell around it: see Fig. 33–7. When much of the hydrogen within the core has been consumed, the production of energy decreases at the center and is no longer sufficient Hydrogen to prevent the huge gravitational forces from once again causing the core to contract and heat up. The hydrogen in the shell around the core then fuses even more fiercely because of this rise in temperature, causing the outer envelope of the star to expand and to cool. The surface temperature, thus reduced, produces a spectrum of light that peaks at longer wavelength (reddish).

Contraction due to gravity

Fusion begins when T $(and \overline{KE})$ is large enough

Proton-proton cycle

Carbon cycle

Reaching the main sequence

FIGURE 33-7 A shell of "burning" hydrogen (fusing to become helium) surrounds the core where the newly formed helium gravitates.

[†]The word "burn" is put in quotation marks because these high-temperature fusion reactions occur via a nuclear process, and must not be confused with ordinary burning (of, say, paper, wood, or coal) in air, which is a *chemical* reaction, occurring at the *atomic* level (and at a much lower temperature).

[‡]More massive stars, since they are hotter and the Coulomb repulsion is more easily overcome, "burn" much more quickly, and so use up their fuel faster, resulting in shorter lives. A star 10 times more massive than our Sun, for example, will remain on the main sequence only for about $10⁷$ years. Stars less massive than our Sun live much longer than our Sun's 10^{10} yr.

FIGURE 33-8 Evolutionary "track" of a star like our Sun represented on an H-R diagram.

Nucleosynthesis

White dwarfs

Production of heavy elements

By this time the star has left the main sequence. It has become redder, and as it has grown in size, it has become more luminous. So it will have moved to the right and upward on the H-R diagram, as shown in Fig. 33–8. As it moves upward, it enters the **red giant** stage. Thus, theory explains the origin of red giants as a natural step in a star's evolution. Our Sun, for example, has been on the main sequence for about $4\frac{1}{2}$ billion years. It will probably remain there another 4 or 5 billion years. When our Sun leaves the main sequence, it is expected to grow in diameter (as it becomes a red giant) by a factor of 100 or more, swallowing up one or more of the inner planets (Mercury, Venus, maybe Earth).

If the star is like our Sun, or larger, further fusion can occur. As the star's outer envelope expands, its core is shrinking and heating up. When the temperature reaches about 10^8 K, even helium nuclei, in spite of their greater charge and hence greater electrical repulsion, can then reach each other and undergo fusion. The reactions are

$$
{}_{2}^{4}\text{He} + {}_{2}^{4}\text{He} \longrightarrow {}_{4}^{8}\text{Be}
$$

$$
{}_{2}^{4}\text{He} + {}_{4}^{8}\text{Be} \longrightarrow {}_{6}^{12}\text{C}
$$

(33-2)

with the emission of two γ rays. These two reactions must occur in quick succession (because ${}^{8}_{4}Be$ is very unstable), and the net effect is

$$
3\,{}^{4}_{2}\text{He} \longrightarrow {}^{12}_{6}\text{C}.\tag{Q = 7.3\,\text{MeV}}
$$

This fusion of helium causes a change in the star which moves rapidly to the "horizontal branch" on the H-R diagram (Fig. 33-8). Further fusion reactions are possible, with ${}_{2}^{4}$ He fusing with ${}_{6}^{12}$ C to form ${}_{8}^{16}$ O. In more massive stars, higher Z elements like ${}^{20}_{10}Ne$ or ${}^{24}_{12}Mg$ can be made. This process of creating heavier nuclei from lighter ones (or by absorption of neutrons which tends to occur at higher Z) is called **nucleosynthesis**.

The final fate of a star depends on its mass. Stars can lose mass as parts of their envelope drift off into space. Stars born with a mass less than about 8 (or perhaps 10) solar masses eventually end up with a residual mass less than about 1.4 solar masses, which is known as the Chandrasekhar limit. For them, no further fusion energy can be obtained. The core of such a "low mass" star (original mass ≤ 8 solar masses) contracts under gravity; the outer envelope expands again and the star becomes an even larger red giant. Eventually the outer layers escape into space, the core shrinks, the star cools, and typically follows the dashed route shown in Fig. 33-8, descending downward, becoming a white dwarf. A white dwarf with a mass equal to that of the Sun would be about the size of the Earth. A white dwarf contracts to the point at which the electron clouds start to overlap, but collapses no further because, as the Pauli exclusion principle claims, no two electrons can be in the same quantum state. Arriving at this point is called *electron degeneracy*. A white dwarf continues to lose internal energy by radiation, decreasing in temperature and becoming dimmer until its light goes out. It has then become a cold dark chunk of ash.

Stars whose residual mass is greater than the Chandrasekhar limit of 1.4 solar masses (original mass greater than about 8 or 10 solar masses) are thought to follow a quite different scenario. A star with this great a mass can contract under gravity and heat up even further. In the range $T = 2.5-5 \times 10^9$ K, nuclei as heavy as ${}^{56}_{26}Fe$ and ${}^{56}_{28}Ni$ can be made. But here the formation of heavy nuclei from lighter ones by fusion, ends. As we saw in Fig. 30–1, the average binding energy per nucleon begins to decrease for \vec{A} greater than about 60. Further fusions would *require* energy, rather than release it.

Elements heavier than Ni are thought to form mainly by neutron capture, particularly in supernova explosions. Large numbers of free neutrons, resulting from nuclear reactions, are present inside highly evolved stars and they can readily combine with, say, a $^{56}_{26}$ Fe nucleus to form (if three are captured) $^{59}_{26}$ Fe, which decays to $^{59}_{27}$ Co. The $^{59}_{27}$ Co can capture neutrons, also becoming neutron

rich and decaying by β^- to the next higher Z element, and so on. The highest Z elements are thought to form by such neutron capture during supernova explosions when hordes of neutrons are available.

Yet at these extremely high temperatures, well above 10^9 K, the kinetic energy of the nuclei is so high that fusion of elements heavier than iron is still possible even though the reactions require energy input. But the high-energy collisions can also cause the breaking apart of iron and nickel nuclei into He nuclei, and eventually into protons and neutrons:

$$
^{56}_{26}\text{Fe} \rightarrow 13 \, ^4_2\text{He} + 41
$$

$$
^{4}_2\text{He} \rightarrow 2p + 2n.
$$

These are energy-requiring (endothermic) reactions, but at such extremely high temperature and pressure there is plenty of energy available, enough even to force electrons and protons together to form neutrons in inverse β decay:

$$
e^- + p \to n + \nu.
$$

As the core collapses under the huge gravitational forces, the tremendous mass becomes essentially an enormous nucleus made up almost exclusively of neutrons. The size of the star is no longer limited by the exclusion principle applied to electrons, but rather applied to neutrons (neutron degeneracy), and the star begins to contract rapidly toward forming an enormously dense **neutron star**. The contraction of the core would mean a great reduction in gravitational potential energy. Somehow this energy would have to be released. Indeed, it was suggested in the 1930s that the final core collapse to a neutron star may be accompanied by a catastrophic explosion whose tremendous energy could form virtually all elements of the periodic table and blow away the entire outer envelope of the star (Fig. 33-9), spreading its contents into interstellar space. Such explosions are believed to produce some of the observed supernovae. The presence of heavy elements on Earth and in our solar system suggests that our solar system formed from the debris of supernovae.

Neutron stars

Supernovae

FIGURE 33-9 These glowing filaments, observed by the Hubble Space Telescope, are remnants of a supernova whose light would have reached Earth thousands of years ago. Inside is a powerful rotating neutron star called a pulsar.

The core of a neutron star contracts to the point at which all neutrons are as close together as they are in a nucleus. That is, the density of a neutron star is on the order of 10^{14} times greater than normal solids and liquids on Earth. A cupful of such dense matter would weigh billion of tons. A neutron star that has a mass 1.5 times that of our Sun would have a diameter of only about 20 km.

If the final mass of a neutron star is less than about two or three solar masses, its subsequent evolution is thought to be similar to that of a white dwarf. If the mass is greater than this, the star collapses under gravity, overcoming even the neutron exclusion principle. Gravity would then be so strong that even light emitted from it could not escape—it would be pulled back in by the force of gravity. Since no radiation could escape from such a star, we could not see it-it would be black. An object may pass by it and be deflected by its gravitational field, but if it came too close it would be swallowed up, never to escape. This is a black hole.

FIGURE 33-10 Hypothetical model for novae and type Ia supernovae, showing how a white dwarf could pull mass from its normal companion.

Type Ia supernovae

Novae and Supernovae

Novae (singular is *nova*, meaning "new" in Latin) are faint stars that have suddenly increased in brightness by as much as a factor of $10⁴$ and last for a month or two before fading. Novae are thought to be faint white dwarfs that have pulled mass from a nearby companion (they make up a *binary* system), as illustrated in Fig. 33–10. The captured mass of hydrogen fuses into helium at a high rate for a few weeks. Many novae (maybe all) are *recurrent*—they repeat their bright glow years later.

Supernovae are also brief explosive events, but release millions of times more energy than novae, up to 10^{10} times more luminous than our Sun. The peak of brightness may equal that of the entire galaxy in which they are located, but lasts only a few days. They remain bright but slowly fade over a few months. Many supernovae form by core collapse to a neutron star as described above.

Type Ia supernovae are different. They all seem to have very nearly the same luminosity. They are believed to be binary stars, one of which is a white dwarf that pulls mass from its companion, much like for a nova, Fig. 33-10. The mass is higher, and as mass is captured and the total mass reaches the Chandrasekhar limit of 1.4 solar masses, the star begins to collapse and then explodes as a supernova.

Distance Measurements

How astronomical distances are measured

We have talked about the vast distances of objects in the universe. But how do we measure these distances? One basic technique employs simple geometry to measure the **parallax** of a star. By parallax we mean the apparent motion of a star, against the background of more distant stars, due to the Earth's motion about the Sun. As shown in Fig. $33-11$, the sighting angle of a star relative to the plane of Earth's orbit (angle θ) can be determined at different times of the year. Since we know the distance d from Earth to Sun, we can reconstruct the right triangles shown in Fig. 33–11 and can determine[†] the distance D to the star.

[†]This is essentially the way the heights of mountains are determined, by "triangulation." See Example 1-9.

FIGURE 33-11 (a) Distance to a star determined by parallax (not to scale!). The imaginary triangles are right triangles and ϕ is a very small angle. (b) View of the sky showing the apparent position of the "nearby" star relative to more distant stars, at two different times (January and July). The viewing angle in January puts the star more to the right relative to distant stars, whereas in July it is more to the left (dashed circle shows January location).

924 CHAPTER 33 Astrophysics and Cosmology

EXAMPLE 33-6 ESTIMATE Distance to a star using parallax. Estimate the distance D to a star if the angle θ in Fig. 33–11 is measured to be 89.99994°

APPROACH From trigonometry, $\tan \phi = d/D$ in Fig. 33–11. The Sun–Earth distance is $d = 1.5 \times 10^8$ km.

 $\phi = 90^{\circ} - 89.99994^{\circ} = 0.00006^{\circ}$. **SOLUTION** The angle or about 1.0×10^{-6} radians. We can use tan $\phi \approx \phi$ since ϕ is very small. We solve for D in $\tan \phi = d/D$. The distance D to the star is

$$
D = \frac{d}{\tan \phi} \approx \frac{d}{\phi} = \frac{1.5 \times 10^8 \text{ km}}{1.0 \times 10^{-6} \text{ rad}} = 1.5 \times 10^{14} \text{ km},
$$

or about 15 ly.

Distances to stars are often specified in terms of parallax angle given in seconds of arc: 1 second (1") is $\frac{1}{60}$ of a minute (') of arc, which is $\frac{1}{60}$ of a degree, so $1'' = \frac{1}{3600}$ of a degree. The distance is then specified in parsecs (meaning *parallax* angle in seconds of arc), where the **parsec** (pc) is defined as $1/\phi$ with ϕ in seconds. In Example 33–6, $\phi = (6 \times 10^{-5})^{\circ} (3600) = 0.22^{\prime\prime}$ of arc, so we would say the star is at a distance of $1/0.22'' = 4.5$ pc. It is easy to show that the parsec is given by

$$
1 pc = 3.26 ly
$$

= (3.26 ly)(9.46 × 10¹⁵ m/ly) = 3.08 × 10¹⁶ m

Parallax can be used to determine the distance to stars as far away as about 100 light-years (\approx 30 parsecs) from Earth, and from an orbiting satellite perhaps 5 to 10 times farther. Beyond that distance, parallax angles are too small to measure. For greater distances, more subtle techniques must be employed. We might compare the apparent brightnesses of two galaxies and use the inverse square law (intensity drops off as the square of the distance) to roughly estimate their relative distances. We can't expect this technique to be very precise because we don't expect all galaxies to have the same intrinsic luminosity. A perhaps better estimate assumes the brightest stars in all galaxies (or the brightest galaxies in galaxy clusters) are similar and have about the same absolute luminosity. Consequently, their *apparent* brightness would be a measure of how far away they were.

Another technique makes use of the H-R diagram. Measurement of a star's surface temperature (from its spectra) places it at a certain point (within 20%) on the H-R diagram, assuming it is a main-sequence star, and then its luminosity can be estimated off the vertical axis (Fig. $33-6$). Its apparent brightness and Eq. 33–1 give its approximate distance; see Example 33–5.

A better estimate comes from comparing variable stars, such as Cepheid *variables* whose averaged intrinsic luminosity (varying in time) has been found to be correlated to their periods.

The largest distances are estimated by comparing the apparent brightnesses of type Ia supernovae (SNIa). Type Ia supernovae all have a similar origin (they collapse to a neutron star at 1.4 solar masses, as described on the previous page and Fig. 33-10), and their brief explosive burst of light is expected to be of nearly the same total luminosity. They are thus sometimes referred to as "standard candles."

Another important technique for estimating distance is from the "redshift" in the line spectra of elements and compounds. The redshift is related to the expansion of the universe, as discussed in Section 33–5. It is useful for objects further than 10^7 to 10^8 ly away.

As we look farther and farther away, the measurement techniques are less and less reliable, so there is more and more uncertainty in the measurements of large distances.

Parsec (unit)

Cepheid variables

SNIa as standard candles

We have seen that the force of gravity plays an important role in the processes that occur in stars. Gravity too is important for the evolution of the universe as a whole. The reasons gravity plays the dominant role in the universe, and not one of the other of the four forces in nature, are (1) it is long-range and (2) it is always attractive. The strong and weak nuclear forces act over very short distances only, on the order of the size of a nucleus; hence they do not act over astronomical distances (they do act between nuclei and nucleons in stars to produce nuclear reactions). The electromagnetic force, like gravity, acts over great distances. But it can be either attractive or repulsive. And since the universe does not seem to contain large areas of net electric charge, a large net force does not occur. But gravity acts as an attractive force between *all* masses, and there are large accumulations in the universe of only the one "sign" of mass (not $+$ and $-$ as with electric charge). However, the force of gravity as Newton described it in his law of universal gravitation shows discrepancies on a cosmological scale. Einstein, in his general theory of relativity, developed a theory of gravity that now forms the basis of cosmological dynamics.

In the special theory of relativity (Chapter 26), Einstein concluded that there is no way for an observer to determine whether a given frame of reference is at rest or is moving at constant velocity in a straight line. Thus the laws of physics must be the same in different inertial reference frames. But what about the more general case of motion where reference frames can be *accelerating*?

Einstein tackled the problem of accelerating reference frames in his general theory of relativity and in it also developed a theory of gravity. The mathematics of General Relativity is complex, so our discussion will be mainly qualitative.

We begin with Einstein's principle of equivalence, which states that

no experiment can be performed that could distinguish between a uniform gravitational field and an equivalent uniform acceleration.

If observers sensed that they were accelerating (as in a vehicle speeding around a sharp curve), they could not prove by any experiment that in fact they weren't simply experiencing the pull of a gravitational field. Conversely, we might think we are being pulled by gravity when in fact we are undergoing an "inertial" acceleration having nothing to do with gravity.

As a thought experiment, consider a person in a freely falling elevator near the Earth's surface. If our observer held out a book and let go of it, what would happen? Gravity would pull it downward toward the Earth, but at the same rate $(g = 9.8 \text{ m/s}^2)$ at which the person and elevator were falling. So the book would hover right next to the person's hand (Fig. 33-12). The effect is exactly the same as if this reference frame was at rest and no forces were acting. On the other hand, if the elevator was out in space where the gravitational field is essentially zero, the released book would float, just as it does in Fig. 33-12. Next, if the elevator (out in space) is accelerating upward at an acceleration of 9.8 m/s^2 , the book as seen by our observer would fall to the floor with an acceleration of 9.8 $m/s²$, just as if it were falling due to gravity at the surface of the Earth. According to the principle of equivalence, the observer could not determine whether the book fell because the elevator was accelerating upward, or because a gravitational field was acting downward and the elevator was at rest. The two descriptions are equivalent.

The principle of equivalence is related to the concept that there are two types of mass. Newton's second law, $F = ma$, uses inertial mass. We might say that inertial mass represents "resistance" to any type of force. The second type of mass is gravitational mass. When one body attracts another by the gravitational force (Newton's law of universal gravitation, $F = Gm_1m_2/r^2$, Chapter 5), the strength of the force is proportional to the product of the gravitational masses of the two bodies. This is much like the electric force

FIGURE 33-12 A freely falling elevator. The released book hovers next to the owner's hand; (b) is a few moments after (a).

 (b)

FIGURE 33-13 (a) Light beam goes straight across an elevator not accelerating. (b) The light beam bends (exaggerated) in an elevator accelerating in an upward direction.

between two bodies which is proportional to the product of their electric charges. The electric charge of a body is not related to its inertial mass; so why should we expect that a body's gravitational mass (call it gravitational charge if you like) be related to its inertial mass? All along we have assumed they were the same. Why? Because no experiment—not even of high precision—has been able to discern any measurable difference between inertial mass and gravitational mass. This is another way to state the equivalence principle: gravitational mass is equivalent to inertial mass.

The principle of equivalence can be used to show that light ought to be deflected due to the gravitational force of a massive body. Consider another thought experiment, in which an elevator is in free space where virtually no gravity acts. If a light beam enters a hole in the side of the elevator, the beam travels straight across the elevator and makes a spot on the opposite side if the elevator is at rest (Fig. 33–13a). If the elevator is accelerating upward, as in Fig. 33-13b, the light beam still travels straight across in a reference frame at rest. In the upwardly accelerating elevator, however, the beam is observed to curve downward. Why? Because during the time the light travels from one side of the elevator to the other, the elevator is moving upward at ever-increasing speed. Next we note that according to the equivalence principle, an upwardly accelerating reference frame is equivalent to a downward gravitational field. Hence, we can picture the curved light path in Fig. 33-13b as being the effect of a gravitational field. Thus, from the principle of equivalence, we expect gravity to exert a force on a beam of light and to bend it out of a straight-line path!

That light is affected by gravity is an important prediction of Einstein's general theory of relativity. And it can be tested. The amount a light beam would be deflected from a straight-line path must be small even when passing a massive body. (For example, light near the Earth's surface after traveling 1 km is predicted to drop only about 10^{-10} m, which is equal to the diameter of a small atom and not detectable.) The most massive body near us is the Sun, and it was calculated that light from a distant star would be deflected by 1.75" of arc (tiny but detectable) as it passed near the Sun (Fig. 33-14). However, such a measurement could be made only during a total eclipse of the Sun, so that the Sun's tremendous brightness would not overwhelm the starlight passing near its edge. An opportune eclipse occurred in 1919, and scientists journeyed to the South Atlantic to observe it. Their photos of stars around the Sun revealed shifts in accordance with Einstein's prediction.

If a light beam can follow a curved path, as discussed above, then perhaps we can say that *space itself is curved* and that it is the gravitational mass that causes the curvature. Indeed, the curvature of space—or rather, of fourdimensional space-time—is a basic aspect of Einstein's General Relativity (GR).

FIGURE 33-14 (a) Three stars in the sky. (b) If the light from one of these stars passes very near the Sun, whose gravity bends the rays, the star will appear higher than it actually is.

What is meant by curved space? To understand, recall that our normal method of viewing the world is via Euclidean plane geometry. In Euclidean geometry, there are many axioms and theorems we take for granted, such as that the sum of the angles of any triangle is 180° . Non-Euclidean geometries, which involve curved space, have also been imagined by mathematicians. It is hard enough to imagine three-dimensional curved space, much less curved fourdimensional space-time. So let us try to understand the idea of curved space by using two-dimensional surfaces.

Consider, for example, the two-dimensional surface of a sphere. It is clearly curved, Fig. 33–15, at least to us who view it from the outside—from our threedimensional world. But how would hypothetical two-dimensional creatures determine whether their two-dimensional space were flat (a plane) or curved? One way would be to measure the sum of the angles of a triangle. If the surface is a plane, the sum of the angles is 180°, as we learn in plane geometry. But if the space is curved, and a sufficiently large triangle is constructed, the sum of the angles will not be 180°. To construct a triangle on a curved surface, say the sphere of Fig. $33-15$, we must use the equivalent of a straight line: that is, the shortest distance between two points, which is called a geodesic. On a sphere, a geodesic is an arc of a great circle (an arc in a plane passing through the center of the sphere) such as the Earth's equator and the Earth's longitude lines. Consider, for example, the large triangle of Fig. 33-15: its sides are two longitude lines passing from the north pole to the equator, and the third side is a section of the equator as shown. The two longitude lines make 90° angles with the equator (look at a world globe to see this more clearly). They make an angle with each other at the north pole, which could be, say, 90° as shown; the sum of these angles is $90^{\circ} + 90^{\circ} + 90^{\circ} = 270^{\circ}$. This is clearly *not* a Euclidean space. Note, however, that if the triangle is small in comparison to the radius of the sphere, the angles will add up to nearly 180°, and the triangle (and space) will seem flat.

Another way to test the curvature of space is to measure the radius r and circumference C of a large circle. On a plane surface, $C = 2\pi r$. But on a two-dimensional spherical surface, C is less than $2\pi r$, as can be seen in Fig. 33–16. The proportionality between C and r is less than 2π . Such a surface is said to have *positive curvature*. On the saddlelike surface of Fig. 33–17, the circumference of a circle is greater than $2\pi r$, and the sum of the angles of a triangle is less than 180°. Such a surface is said to have a *negative curvature*.

Curvature of the Universe

Now, what about our universe? On a large scale (not just near a large mass), what is the overall curvature of the universe? Does it have positive curvature, negative curvature, or is it flat (zero curvature)?

The universe: open or closed?

If the universe had a positive curvature, the universe would be *closed*, or *finite* in volume. This would *not* mean that the stars and galaxies extended out to a certain boundary, beyond which there is empty space. There is no boundary or edge in such a universe. If a particle were to move in a straight line in a particular direction, it would eventually return to the starting point—perhaps eons of time later.

Geodesic

FIGURE $33-15$ On a twodimensional curved surface, the sum of the angles of a triangle may not be 180°.

FIGURE 33-16 On a spherical surface (a two-dimensional world) a circle of circumference C is drawn about point O as the center. The radius of the circle (not the sphere) is the distance r along the surface. (Note that in our threedimensional view, we can tell that $2\pi a = C$; since $r > a$, then $2\pi r > C$.)

On the other hand, if the curvature of space was zero or negative, the universe would be *open*. It could just go on forever. An open universe could be infinite, but not necessarily according to recent research.

Today the evidence is very strong that the universe on a large scale is very close to being flat. Indeed, it is so close to being flat that we can't tell if it might be very slightly positive or very slightly negative.

Black Holes

According to Einstein's theory, space-time is curved near massive bodies. We might think of space as being like a thin rubber sheet: if a heavy weight is hung from it, it curves as shown in Fig. 33–18. The weight corresponds to a huge mass that causes space (space itself!) to curve. Thus, in Einstein's theory[†] we do not speak of the "force" of gravity acting on bodies. Instead we say that bodies and light rays move as they do because space-time is curved. A body at rest or moving slowly near the great mass of Fig. 33–18 would follow a geodesic (the equivalent of a straight line in plane geometry) toward that body.

The extreme curvature of space-time shown in Fig. 33–18 could be produced by a **black hole**. A black hole, as we saw in the Section 33-2, is so dense that even light cannot escape from it. To become a black hole, a body of mass M must undergo gravitational collapse, contracting by gravitational selfattraction to within a radius called the **Schwarzschild radius**:

$$
R=\frac{2GM}{c^2},
$$

where G is the gravitational constant and c the speed of light.

The Schwarzschild radius also represents the event horizon of a black hole. By event horizon we mean the surface beyond which no signals can ever reach us, and thus inform us of events that happen. As a star collapses toward a black hole, the light it emits is pulled harder and harder by gravity, but we can still see it. Once the matter passes within the event horizon the emitted light cannot escape, but is pulled back in by gravity.

All we can know about a black hole is its mass, its angular momentum (there could be rotating black holes), and its electric charge. No other information, no details of its structure or the kind of matter it was formed of, can be known because no information can escape.

How might we observe black holes? We cannot see them because no light can escape from them. They would be black objects against a black sky. But they do exert a gravitational force on nearby bodies. The black hole believed to be at the center of our Galaxy was discovered by examining the motion of matter in its vicinity. Another technique is to examine stars which appear to be rotating as if they were members of a *binary system* (two stars rotating about their common center of mass), although the companion is invisible. If the unseen star is a black hole, it might be expected to pull off gaseous material from its visible companion (as in Fig. 33-10). As this matter approached the black hole, it would be highly accelerated and should emit X-rays of a characteristic type before plunging inside the event horizon. Such X-rays, plus a sufficiently high mass estimate from the rotational motion, can provide evidence for a black hole. One of the many candidates for a black hole is in the binary-star system Cygnus X-1.

[†] Alexander Pope (1688–1744) wrote an epitaph for Newton:

"Nature, and Nature's laws lay hid in night:

God said, Let Newton be! and all was light."

Sir John Squire (1884-1958), perhaps uncomfortable with Einstein's profound thoughts, added:

"It did not last: the Devil howling 'Ho! Let Einstein be!' restored the status quo." **Black holes** Weight

Event horizon

FIGURE 33-19 Atoms and molecules emit and absorb light of particular frequencies depending on the spacing of their energy levels, as we saw in Chapters 27, 28, and 29. (a) The spectrum of light received from a relatively slow-moving galaxy, where $Z = (\lambda - \lambda_0)/\lambda_0$. (b) Spectrum of a galaxy moving away from us at a much higher speed. Note how the peaks (or lines) in the spectrum have moved to longer wavelengths (the redshift).

Redshift parameter (defined)

33-5 The Expanding Universe: **Redshift and Hubble's Law**

We discussed in Section 33–2 how individual stars evolve from their birth to their death as white dwarfs, neutron stars, and black holes. But what about the universe as a whole: is it static, or does it change? One of the most important scientific results of the twentieth century was that distant galaxies are racing away from us, and that the farther they are from us, the faster they are moving away. How astronomers arrived at this astonishing idea, and what it means for the past history of the universe as well as its future, will occupy us for the remainder of the book.

That the universe is expanding was first put forth by Edwin Hubble in 1929. This idea was based on distance measurements of galaxies (Section 33–3), and determination of their velocities by the Doppler shift of spectra lines in the light received from them (Fig. $33-19$). In Chapter 12 we saw how the frequency and wavelength of sound are altered if the source is moving toward or away from an observer. If the source moves toward us, the frequency is higher and the wavelength is shorter. If the source moves away from us, the frequency is lower and the wavelength is longer. The Doppler effect occurs also for light, but the shifted wavelength or frequency is given by a formula slightly different[†] from that for sound. According to special relativity, the Doppler shift is given by

$$
\lambda = \lambda_0 \sqrt{\frac{1 + v/c}{1 - v/c}},
$$
 [source and observer moving
away from each other] (33-3)

where λ_0 is the emitted wavelength as seen in a reference frame at rest with respect to the source, and λ is the wavelength measured in a frame moving with velocity v away from the source along the line of sight. (For relative motion *toward* each other, $v < 0$ in this formula.) When a distant source emits light of a particular wavelength, and the source is moving away from us, the wavelength appears longer to us: the color of the light (if it is visible) is shifted toward the red end of the visible spectrum, an effect known as a redshift. (If the source moves toward us, the color shifts toward the blue or shorter wavelength.) The amount of a redshift is specified by the *redshift parameter*, z, defined as

$$
z = \frac{\lambda}{\lambda_0} - 1 = \frac{\lambda - \lambda_0}{\lambda_0} = \frac{\Delta \lambda}{\lambda_0}.
$$
 (33-4)

We can combine Eqs. $33-4$ and $33-3$ to obtain³

$$
z = \sqrt{\frac{1 + v/c}{1 - v/c}} - 1.
$$
 (33-5a)

For speeds not too close to the speed of light, it is easy to show (Problem 29) that z is proportional to the speed of the source to or away from us (as was the case for sound):

$$
z = \frac{\lambda - \lambda_0}{\lambda_0} \approx \frac{v}{c}.
$$
 [v \ll c] (33-5b)

But redshifts are not always small, in which case the approximation of Eq. 33–5b would not be valid. Modern telescopes regularly observe galaxies with $z \approx 5$.

⁷For light there is no medium and we can make no distinction between motion of the source and motion of the observer (special relativity), as we did for sound which travels in a medium (Chapter 12).

[‡]Equation 33–5a for z is not precisely correct because, strictly speaking, the redshift is due to the expansion of space, not motion through space (Doppler effect, Eq. 33-3).

EXAMPLE 33-7 Given z, what is v ? What is the speed of a galaxy whose redshift parameter is measured to be $z = 5$?

APPROACH We make an approximation by using the Doppler formula, Eq. 33–5a (see footnote \ddagger on previous page), and solve for v.

SOLUTION We add 1 to both sides of Eq. 33-5a:

$$
z + 1 = \sqrt{\frac{1 + v/c}{1 - v/c}}.
$$

We set $z = 5$ and square both sides of this equation, and then solve for v :

$$
62 = \frac{1 + v/c}{1 - v/c}
$$

$$
36\left(1 - \frac{v}{c}\right) = 1 + \frac{v}{c}.
$$

We collect terms in v/c on one side:

$$
35 = 37 \frac{v}{c},
$$

$$
v = \frac{35}{37} c = 0.95c.
$$

SO.

NOTE This speed represents how fast the universe (and space itself) is expanding at the position of this galaxy as viewed from Earth.

EXERCISE C If $v = 0.70c$, what is z?

In the spectra of stars in other galaxies, lines are observed that correspond to lines in the known spectra of particular atoms (see Section $27-11$). What Hubble found was that the lines seen in the spectra from distant galaxies were generally redshifted, and that the amount of shift seemed to be approximately proportional to the distance of the galaxy from us. That is, the velocity, v , of a galaxy moving away from us is proportional to its distance, d , from us:

 $v = Hd$.

This is Hubble's law, one of the most fundamental astronomical ideas. The constant H is called the **Hubble parameter**. Hubble's law does not work well for nearby galaxies-in fact nearby galaxies can even be "blueshifted" (moving toward us) which merely represents random local motion. For more distant galaxies, the velocity of recession (Hubble's law) is much greater than that of random motion, and so is dominant. We then say it is a cosmological redshift, and we have come to view it as due to the expansion of space itself. Indeed, we can think of the originally emitted wavelength λ_0 as being stretched out (becoming longer) along with the expanding space around it.

The value of H until recently was uncertain by over 20%, and thought to be between 50 and 80 km/s/Mpc. But recent (2003) measurements now put its value more precisely at

$$
H = 71 \,\mathrm{km/s/Mpc}
$$

(that is, 71 km/s per megaparsec of distance). The uncertainty is about 5% , or \pm 4 km/s/Mpc. If we use light-years for distance, then $H = 22$ km/s per million light-years of distance:

$$
H \approx 22 \text{ km/s/Mly}
$$

with an estimated uncertainty of $\pm 1 \text{ km/s/Mly.}$

SECTION 33-5 The Expanding Universe: Redshift and Hubble's Law 931

 $(33-6)$

Hubble parameter

HUBBLE'S LAW

What does it mean that distant galaxies are all moving away from us, and with ever greater speed the farther they are from us? It seems to suggest some kind of explosive expansion that started at some very distant time in the past. And at first sight we seem to be in the middle of it all. But we aren't. The expansion appears the same from any other point in the universe. To understand why, see Fig. 33-20. In Fig. 33-20a we have the view from Earth (or from our Galaxy). The velocities of surrounding galaxies are indicated by arrows, pointing away from us, and the arrows are longer for galaxies more distant from us. Now, what if we were on the galaxy labeled A in Fig. 33–20a? From Earth, galaxy A appears to be moving to the right at a velocity, call it \vec{v}_A , represented by the arrow pointing to the right. If we were on galaxy A, Earth would appear to be moving to the left at velocity $-\vec{v}_A$. To determine the velocities of other galaxies relative to A, we vectorially add the velocity vector, $-\vec{v}_A$, to all the velocity arrows shown in Fig. 33-20a. This yields Fig. 33-20b, where we see clearly that the universe is expanding away from galaxy A as well; and the velocities of galaxies receding from A are proportional to their distance from A.

FIGURE 33-20 Expansion of the universe looks the same from any point in the universe.

Thus the expansion of the universe can be stated as follows: All galaxies are racing away from each other at an average rate of about 71 km/s per megaparsec of distance between them. The ramifications of this idea are profound, and we discuss them in a moment.

Cosmological principle

A basic assumption in cosmology has been that on a large scale, the universe would look the same to observers at different places at the same time. In other words, the universe is both *isotropic* (looks the same in all directions) and homogeneous (would look the same if we were located elsewhere, say in another galaxy). This assumption is called the cosmological principle. On a local scale, say in our solar system or within our Galaxy, it clearly does not apply (the sky looks different in different directions). But it has long been thought to be valid if we look on a large enough scale, so that the average population density of galaxies and clusters of galaxies ought to be the same in different areas of the sky. This seems to be valid on distances greater than about 200 Mpc (700 Mly). The expansion of the universe (Fig. 33-20) is consistent with the cosmological principle; and the near uniformity of the cosmic microwave background radiation (discussed in Section 33–6) supports it.

The expansion of the universe, as described by Hubble's law, strongly suggests that galaxies must have been closer together in the past than they are now. This is, in fact, the basis of the Big Bang theory of the origin of the universe, which pictures the universe as a relentless expansion starting from a very hot and compressed beginning. We discuss the Big Bang in detail shortly, but first let us see what can be said about the age of the universe.

One way to estimate the age of the universe uses the Hubble parameter. With $H \approx 22 \text{ km/s}$ per 10⁶ light-years, the time required for the galaxies to arrive at their present separations would be approximately (starting with $v = d/t$ and using Hubble's law, Eq. 33–6),

$$
t = \frac{d}{v} = \frac{d}{Hd} = \frac{1}{H} \approx \frac{(10^6 \text{ ly})(0.95 \times 10^{13} \text{ km/ly})}{(22 \text{ km/s})(3.16 \times 10^7 \text{ s/yr})} \approx 13.7 \times 10^9 \text{ yr}
$$

or 13.7 billion years. The age of the universe calculated in this way is called the characteristic expansion time or "Hubble age." It is a rough estimate and assumes the rate of expansion of the universe was constant (which today we are quite sure is not true). Recent precise measurements (2003) give the age as 13.7×10^9 yr, in remarkable agreement with the rough Hubble age estimate.

* Steady-State Model

Before discussing the Big Bang in detail, we mention one alternative to the Big Bang—the steady-state model—which assumed that the universe is infinitely old and on average looks the same now as it always has. (This assumed uniformity in time as well as space was called the *perfect cosmological principle*.) According to the steady-state model, no large-scale changes have taken place in the universe as a whole, particularly no Big Bang. To maintain this view in the face of the recession of galaxies away from each other, mass-energy conservation must be violated. That is, matter must be created continuously to maintain the assumption of uniformity. The rate of mass creation required is very small—about one nucleon per cubic meter every 10⁹ years.

The steady-state model provided the Big Bang model with healthy competition in the mid-twentieth century. But the discovery of the cosmic microwave background radiation (next Section), as well as the observed expansion of the universe, has made the Big Bang model almost universally accepted.

33-6 The Big Bang and the **Cosmic Microwave Background**

The expansion of the universe seems to suggest that typical objects in the universe were once much closer together than they are now. This is the basis for the idea that the universe began about 13.7 billion years ago as an expansion from a state of very high density and temperature known affectionately as the Big Bang.

The Big Bang was not an explosion, because an explosion blows pieces out into the surrounding space. Instead, the Big Bang was the start of an expansion of space itself. The volume of the observable universe was very small at the start and has been expanding ever since. The initial tiny volume of extremely dense matter is not to be thought of as a concentrated mass in the midst of a much larger space around it. The initial tiny but dense volume was the universe—the entire universe. There wouldn't have been anything else. When we say that the universe was once smaller than it is now, we mean that the average separation between galaxies (or other objects) was less. Thus, it is the size of the universe itself that has increased since the Big Bang.

A major piece of evidence supporting the Big Bang is the cosmic microwave **background** radiation (or CMB) whose discovery came about as follows.

In 1964, Arno Penzias and Robert Wilson were experiencing difficulty with what they assumed to be background noise, or "static," in their radio telescope (a large antenna device for detecting radio waves from the heavens, Fig. 33–21). Eventually, they became convinced that it was real and that it was coming from outside our Galaxy. They made precise measurements at a wavelength $\lambda = 7.35$ cm, in the microwave region of the electromagnetic spectrum (Fig. 22–8). The intensity of this radiation was found initially not to vary by day or night or time of year, nor to depend on direction. It came from all directions in the universe with equal intensity, to a precision of better than 1% . It could only be concluded that this radiation came from the universe as a whole.

Age of the universe

The Big Bang

FIGURE 33-21 Robert Wilson (left) and Arno Penzias, and behind them their "horn antenna."

The 2.73-K cosmic microwave background radiation

The intensity of this cosmic microwave background radiation as measured at $\lambda = 7.35$ cm corresponds to blackbody radiation (see Section 27–2) at a temperature of about 3 K. When radiation at other wavelengths was measured, the intensities were found to fall on a blackbody curve as shown in Fig. 33-22, corresponding to a temperature of 2.725 K.

The remarkable uniformity of the cosmic microwave background radiation was in accordance with the cosmological principle. But theorists felt that there needed to be some small inhomogeneities, or "anisotropies," in the CMB that would have provided "seeds" around which galaxy formation could have started. Small areas of slightly higher density and temperature, which could have contracted under gravity to form stars and galaxies, were indeed found. These tiny inhomogeneities were detected first by the COBE (Cosmic Background Explorer) satellite experiment (1992) and by subsequent experiments with greater detail, culminating in 2003 with the WMAP (Wilkinson Microwave Anisotropy Probe) results. See Fig. 33–23. WMAP gives the CMB temperature as 2.725 ± 0.002 K.

The CMB provides strong evidence in support of the Big Bang, and gives us information about conditions in the very early universe. In fact, in the late 1940s, George Gamow and his collaborators calculated that a Big Bang origin of the universe should have generated just such a microwave background radiation.

FIGURE 33-23 The cosmic microwave background radiation over the entire sky, color-coded to represent differences in temperature from the average 2.725 K: the color scale ranges from $+200 \mu K$ (red) to $-200 \mu K$ (dark blue), representing slightly hotter and colder spots (and also variations in density). Results are from the WMAP satellite in 2003: the angular resolution is 0.2°. The larger version of WMAP at the start of this Chapter was done at a specific frequency band and includes our Galaxy in the foreground (red stripe) which here has been subtracted out.

microwave background radiation, showing blackbody curve and experimental measure-

Importance of CMB: the Big Bang

To understand why, let us look at what a Big Bang might have been like. The temperature must have been extremely high at the start, so high that there could not have been any atoms in the very early stages of the universe. Instead, the universe would have consisted solely of radiation (photons) and a plasma of charged electrons and other elementary particles. The universe would have been opaque—the photons in a sense "trapped," traveling very short distances before being scattered again, primarily by electrons. Indeed, the details of the microwave background radiation is strong evidence that matter and radiation were once in equilibrium at a very high temperature. As the universe expanded, the energy spread out over an increasingly larger volume and the temperature dropped. Only when the temperature had fallen to about 3000 K, some 380,000 years later, could nuclei and electrons combine together as atoms. With the disappearance of free electrons, as they combined with nuclei to form atoms, the radiation would have been freed-decoupled from matter, we say. The universe became *transparent* because photons were now free to travel nearly unimpeded straight through the universe.

As the universe expanded, so too the wavelengths of the radiation lengthened (you might think of standing waves, Section $11-13$), thus redshifting to longer wavelengths that correspond to lower temperature (recall Wien's law, $\lambda_p T$ = constant, Section 27-2), until they would have reached the 2.7-K background radiation we observe today.

* Looking Back toward the Big Bang—Lookback Time

Figure 33–24 shows our Earth point of view, looking out in all directions back toward the Big Bang and the brief (380,000 year long) period when radiation was trapped in the early plasma (yellow band). The time it takes light to reach us from an event (say 5×10^9 yr ago) is called its **lookback time**. The "close-up" insert in Fig. 33-24 shows a photon scattering repeatedly inside the plasma and then exiting the plasma in a straight line. No matter what direction we look, our view of the very early universe is blocked by this wall of plasma—we can see only as far as its surface, called the "surface of last scattering," but not into it. Wavelengths from there are redshifted by $z \approx 1000$. Time $\Delta t'$ in Fig. 33–24 is the lookback time (not real time that goes forward).

FIGURE 33-24 When we look out from the Earth, we look back in time. Any other observer in the universe would see the same thing. The farther an object is from us, the earlier in time the light we see left it. We cannot see quite as far as the Big Bang; we can see only as far as the "surface of last scattering," which represents the CMB. The blowup shows the earliest 380,000 years of the universe when it was opaque: a photon is shown scattering many times and then (at decoupling, 380,000 yr after the Big Bang) becoming free to travel in a straight line. If this photon wasn't heading our way when "liberated," many others were. Galaxies are not shown, but would be concentrated close to Earth in this diagram. Note: This diagram is not a normal map. Maps show a section of the world as might be seen all $at a given$ time. This diagram shows space (like a map), but each point is not at the same time. The light coming from a point a distance r from Earth took a time $\Delta t' = r/c$ to reach Earth, and thus shows an event that took place long ago, a time $\Delta t' = r/c$ in the past, which we call its "lookback time." The Big Bang happened $\Delta t_0' = 13.7$ Gyr ago.

33-7 The Standard Cosmological Model: the Early History of the Universe

In the last decade or two, a convincing theory of the origin and evolution of the universe has developed, now called the **standard cosmological model**, or (sometimes) the concordance model. Part of this theory is based on recent theoretical and experimental advances in elementary particle physics. Indeed, cosmology and elementary particle physics have cross-fertilized to a surprising extent.

Let us go back to the earliest of times—as close as possible to the Big Bang and follow a standard model scenario of events as the universe expanded and cooled after the Big Bang. Initially we talk of extremely small time intervals as well as extremely high temperatures, far beyond anything in the universe today. Figure 33–25 is a compressed graphical representation of the events, and it may be helpful to consult it as we go along.

FIGURE 33-25 Compressed graphical representation of the development of the universe after the Big Bang, according to modern cosmology. [The time scale is mostly logarithmic (each factor of 10 in time gets equal treatment), except at the start (there can be no $t = 0$ on a log scale), and just after $t = 10^{-35}$ (to save space). The vertical height is a rough idea of the size of the universe, mainly to suggest expansion of the universe.]

The History

Modern cosmology "scenario" of the history of the universe after the Big Bang

All four forces unified

We begin at a time only a minuscule fraction of a second after the Big Bang, 10^{-43} s. This is an unimaginably short time, and predictions can be only speculative. Earlier, we can say nothing because we do not yet have a theory of quantum effects on gravity which would be needed for the incredibly high densities and temperatures then. It is thought that prior to 10^{-35} s, perhaps as early as 10^{-43} s, the four forces in nature were unified—there was only one force. The temperature would have been about 10^{32} K, corresponding to particles moving about every which way with an average kinetic energy KE of 10^{19} GeV (see Eq. 13-8):

$$
\kappa \mathbf{E} \approx kT \approx \frac{(1.4 \times 10^{-23} \,\text{J/K})(10^{32} \,\text{K})}{1.6 \times 10^{-19} \,\text{J/eV}} \approx 10^{28} \,\text{eV} = 10^{19} \,\text{GeV}
$$

Symmetry broken (gravity condensed out)

(Note that the factor $\frac{3}{2}$ in Eq. 13–8 is usually ignored in such order of magnitude calculations.) At $t = 10^{-43}$ s, a kind of "phase transition" is believed to have occurred during which the gravitational force, in effect, "condensed out" as a separate force. This, and subsequent phase transitions, are analogous to the phase transitions water undergoes as it cools from a gas, condenses into a liquid, and with further cooling freezes into ice.[†] The symmetry of the four forces was broken, but the strong, weak, and electromagnetic forces were still unified, and the

[†]It may be fun to note that our story of origins here bears some resemblance to ancient accounts that mention the "void," "formless wasteland," "abyss," "divide the waters" (possibly a phase transition?), not to mention the sudden appearance of light.

universe entered the grand unified era (see Chapter 32). There was no distinction between quarks and leptons; baryon and lepton numbers were not conserved. Very shortly thereafter, as the universe expanded considerably and the temperature had dropped to about 10^{27} K, there was another phase transition and the strong force condensed out at about 10^{-35} s after the Big Bang. Now the universe was filled with a "soup" of leptons and quarks. The quarks were initially free, but soon began to "condense" into more normal particles: nucleons and the other hadrons and their antiparticles. With this confinement of quarks, the universe entered the hadron era.

About this time, when the universe was only 10^{-35} s old, a strange thing may have happened, according to theorists. A brilliant idea, proposed around 1980, suggests that the universe underwent an incredible exponential expansion, increasing in size by a factor of 10^{40} or 10^{50} in a tiny fraction of a second, perhaps 10^{-34} s. The usefulness of this **inflationary scenario** is that it solved major problems with earlier Big Bang models, such as explaining why the universe is flat, as well as the thermal equilibrium to provide the nearly uniform CMB.[†] Inflation is now a generally accepted aspect of Big Bang theory.

After the very brief inflationary period, the universe would have settled back into its more regular expansion. The universe was now a "soup" of leptons and hadrons. We can think of this "soup" as a grand mixture of particles and antiparticles, as well as photons-all in roughly equal numbers-colliding with one another frequently and exchanging energy.

By the time the universe was only about a microsecond $(10^{-6} s)$ old, it had cooled to about 10^{13} K, corresponding to an average kinetic energy of 1 GeV , and the vast majority of hadrons disappeared. To see why, let us focus on the most familiar hadrons: nucleons and their antiparticles. When the average kinetic energy of particles was somewhat higher than 1 GeV, protons, neutrons, and their antiparticles were continually being created out of the energies of collisions involving photons and other particles, such as

$$
\begin{array}{rcl}\n\text{photons} & \rightarrow \ p + \bar{p} \\
\rightarrow \ n + \bar{n}.\n\end{array}
$$

But just as quickly, particles and antiparticles would annihilate: for example

 $p + \overline{p} \rightarrow$ photons or leptons.

So the processes of creation and annihilation of nucleons were in equilibrium. The numbers of nucleons and antinucleons were high—roughly as many as there were electrons, positrons, or photons. But as the universe expanded and cooled, and the average kinetic energy of particles dropped below about 1 GeV, which is the minimum energy needed in a typical collision to create nucleons and antinucleons (about 940 MeV each), the process of nucleon creation could not continue. The process of annihilation could continue, however, with antinucleons annihilating nucleons, until there were almost no nucleons left. But not quite zero. To explain our present world, which consists mainly of matter (nucleons and electrons) with very little antimatter in sight, we must suppose that earlier in the universe, perhaps around 10^{-35} s after the Big Bang, a slight excess of quarks over antiquarks was formed. This would

[†]How inflation explains flatness might be understood by thinking of a sphere. If the sphere of Fig. 33-15, with obvious curvature of its surface, were to increase vastly in size, the surface would seem essentially flat to an observer on it. Inflation also explains why the CMB is so uniform. Without inflation, the tiny universe at 10^{-35} s was still too large for all parts of it to have been in contact so as to reach the same temperature (information cannot travel faster than c). Suppose the universe was about 1 cm in diameter at $t \approx 10^{-36}$ s, as per original Big Bang theory. In that 10^{-36} s light could have traveled $d = ct = (3 \times 10^8 \text{ m/s})(10^{-36} \text{/s}) \approx 10^{-27} \text{ m}$, way too small for opposite sides of a 1-cm-wide universe to have been in communication. But if the universe had been 10^{40} or 10^{50} times smaller, there could have been contact and thermal equilibrium to produce the observed nearly uniform CMB. Thus inflation allows the very early universe before inflation to have been so small that all parts could have been in thermal equilibrium, and after inflation large enough to give us today's universe.

Ouark confinement

Inflation

Most hadrons disappear

Why is there matter now?

SECTION 33-7 The Standard Cosmological Model: the Early History of the Universe 937

FIGURE 33-25 (repeated) Compressed graphical representation of the development of the universe after the Big Bang, according to modern cosmology.

have resulted in a slight excess of nucleons over antinucleons. And it is these "leftover" nucleons that we are made of today. The excess of nucleons over antinucleons was about one part in 10^9 . Earlier, during the hadron era, there should have been about as many nucleons as photons. After it ended, the "leftover" nucleons thus numbered only about one nucleon per $10⁹$ photons, and this ratio has persisted to this day. Protons, neutrons, and all other heavier particles were thus tremendously reduced in number by about 10^{-6} s after the Big Bang. The lightest hadrons, the pions, disappeared as the nucleons had; because they are the lightest mass hadrons (140 MeV), they were the last hadrons to go, about 10^{-4} s after the Big Bang. Lighter particles, including electrons and neutrinos, were the dominant form of matter, and the universe entered the lepton era.

Lepton era

Radiation-dominated universe

Making He nuclei

By the time the first full second had passed (clearly the most eventful second in history!), the universe had cooled to about 10 billion degrees, 10^{10} K. The average kinetic energy was about 1 MeV. This was still sufficient energy to create electrons and positrons and balance their annihilation reactions, since their masses correspond to about 0.5 MeV. So there were about as many e^+ and e^- as there were photons. But within a few more seconds, the temperature had dropped sufficiently so that e^+ and e^- could no longer be formed. Annihilation $(e^+ + e^- \rightarrow$ photons) continued. And, like nucleons before them, electrons and positrons all but disappeared from the universe—except for a slight excess of electrons over positrons (later to join with nuclei to form atoms). Thus, about $t = 10$ s after the Big Bang, the universe entered the **radiation era**. Its major constituents were photons and neutrinos. But the neutrinos, partaking only in the weak force, rarely interacted. So the universe, until then experiencing significant amounts of energy in matter and in radiation, now became radiation-dominated: much more energy was contained in radiation than in matter, a situation that would last tens of thousands of years (Fig. 33–25).

Meanwhile, during the next few minutes, crucial events were taking place. Beginning about 2 or 3 minutes after the Big Bang, nuclear fusion began to occur. The temperature had dropped to about 10^9 K, corresponding to an average kinetic energy $\overline{KE} \approx 100 \text{ keV}$, where nucleons could strike each other and be able to fuse (Section $31-3$), but now cool enough so newly formed nuclei would not be immediately broken apart by subsequent collisions. Deuterium, helium, and very tiny amounts of lithium nuclei were probably made. But the universe was cooling too quickly, and larger nuclei were not made. After only a few minutes, probably not even a quarter of an hour after the Big Bang, the temperature dropped far enough that nucleosynthesis stopped, not to start again for millions of years (in stars). Thus, after the first hour or so of the universe, matter consisted mainly of bare nuclei of hydrogen (about 75%) and helium (about 25%)[†] and electrons. But radiation (photons) continued to dominate.

Our story is almost complete. The next important event is presumed to have occurred 380,000 years later. The universe had expanded to about $\frac{1}{1000}$ of its present size, and the temperature had cooled to about 3000 K. The average kinetic energy of nuclei, electrons, and photons was less than an electron volt. Since ionization energies of atoms are on the order of eV, then as the temperature dropped below this point, electrons could orbit the bare nuclei and remain there (without being ejected by collisions), thus forming atoms. With the birth of atoms, the photons—which had been continually scattering from the free electrons-now became free to spread nearly unhindered throughout the universe. As mentioned in the previous Section, the photons became decoupled from matter. The total energy contained in radiation had been decreasing (lengthening in wavelength as the universe expanded), and even before decoupling (at about $t = 56,000 \text{ yr}$) the total energy contained in matter became dominant. The universe was said to have become matter-dominated. As the universe continued to expand, the electromagnetic radiation cooled further, to 2.7 K today, forming the cosmic microwave background radiation we detect from everywhere in the universe.

After the birth of atoms, then stars and galaxies could begin to form-presumably by self-gravitation around mass concentrations (inhomogeneities). Stars began to form about 200 million years after the Big Bang, galaxies after almost 10^9 years. The universe continued to evolve until today, some 13.7 billion years later.

This scenario is by no means "proven." But it does provide a workable picture, for the first time, of how the universe may have begun and evolved.

* * *

A major event, and something only discovered very recently, is that when the universe was about half as old as it is now $(5-7 \text{ Gyr ago})$, its expansion began to accelerate. This was a big surprise because it was assumed the expansion of the universe would slow down due to gravitational attraction of all objects to each other. Indeed, another major recent discovery is that ordinary matter makes up very little of the total mass-energy of the universe ($\approx 4\%$). Instead, as we discuss in the next Section, the major contributors to the energy density of the universe are dark matter and dark energy. On the right in Fig. 33–25 is a narrow vertical strip that represents the most recent 5 to 7 billion years of the universe, during which *dark energy* seems to have dominated.

33-8 Dark Matter and Dark Energy

According to the standard Big Bang model, the universe is evolving and changing. Individual stars are being created, evolving, and dying as white dwarfs, neutron stars, black holes. At the same time, the universe as a whole is expanding. One important question is whether the universe will continue to expand forever. Until the late 1990s, the universe was thought to be dominated by matter which interacts by gravity, and this question was connected to the curvature of space-time (Section 33-4). If the universe had *negative* curvature, the expansion of the universe would never stop, although the rate of expansion would decrease due to the gravitational attraction of its parts. Such a universe would be *open* and infinite. If the universe is *flat* (no curvature), it would still be open and infinite but its expansion would slowly approach a zero rate. Finally, if the universe had *positive* curvature, it would be *closed* and finite; the effect of gravity would be strong enough that the expansion would eventually stop and the universe would begin to contract, collapsing back onto itself in a big crunch.

[†]This standard model prediction of a 25% primordial production of helium agrees with what we observe today—the universe does contain about 25% He—and it is strong evidence in support of the standard Big Bang model. Furthermore, the theory says that 25% He abundance is fully consistent with there being three neutrino types, which is the number we observe. And it sets an upper limit of four to the maximum number of possible neutrino types. Here we have a situation where cosmology actually makes a specific prediction about fundamental physics.

Birth of stable atoms

Matter-dominated universe

Critical Density

According to the above scenario (which does not include the recently discovered acceleration of the universe), the fate of the universe would depend on the average mass density in the universe. For an average mass density greater than a critical value known as the critical density, estimated to be about

Critical density of the universe

 $\rho_c \approx 10^{-26}$ kg/m³

(i.e., a few nucleons/ $m³$ on average throughout the universe), gravity would prevent expansion from continuing forever. Eventually (if $\rho > \rho_c$) gravity would pull the universe back into a big crunch and space-time would have a positive curvature. If instead the actual density was equal to the critical density, $\rho = \rho_c$, the universe would be flat and open. If the actual density was less than the critical density, $\rho < \rho_c$, the universe would have negative curvature. See Fig. 33–26. Today we believe the universe is very close to flat. But recent evidence suggests the universe is expanding at an *accelerating* rate, as discussed below.

FIGURE 33-26 Three future possibilities for the universe, depending on the density ρ of ordinary matter, plus a fourth possibility that includes dark energy. Note that all curves have been chosen to have the same slope $(= H,$ the Hubble parameter) right now. Looking back in time, the Big Bang occurs where each curve touches the horizontal (time) axis.

Dark matter

Dark Matter

WMAP and other experiments have convinced scientists that the universe is flat and $\rho = \rho_c$. But this ρ cannot be only normal baryonic matter (atoms are 99.9% baryons—protons and neutrons—by weight). These recent experiments put the amount of normal baryonic matter in the universe at only 4% of the critical density. What is the other 96%? There is strong evidence for a significant amount of nonluminous matter in the universe referred to as **dark matter**. For example, observations of the rotation of galaxies suggest that they rotate as if they had considerably more mass than we can see. Recall from Chapter 5, Example 5–14 (p. 123), that for a satellite revolving around Earth (mass M)

$$
m\frac{v^2}{r} = G\frac{mM}{r^2}
$$

and hence $v = \sqrt{GM/r}$. If we apply this equation to stars in a galaxy, we see that their speed depends on galactic mass. Observations show that stars farther from the galactic center revolve much faster than expected from visible matter, suggesting a great deal of invisible matter. Similarly, observations of the motion of galaxies within clusters also suggest that they have considerably more mass than can be seen. What might this nonluminous matter in the universe be? We don't know yet. It cannot be made of ordinary (baryonic) matter, so it must consist of some other sort of elementary particle.

Dark matter makes up about 23% of the mass-energy of the universe, according to the latest experiments. Thus the total mass-energy is 23% dark matter plus 4% baryons for a total of 27%, which does not bring ρ up to ρ_c . What is the other 73%? We are not sure about that either, but we have given it the name "dark energy."

Dark Energy-Cosmic Acceleration

Just before the year 2000, cosmologists received a surprise. Gravity was assumed to be the predominant force on a large scale in the universe, and it was thought that the expansion of the universe ought to be slowing down in time because gravity acts as an attractive force between objects. But measurements on type Ia supernovae (SNIa, our best standard candles-see Section 33-3) unexpectedly showed that very distant (high z) SNIa's were dimmer than expected. That is, given their great distance d as determined from their low brightness, their speed v determined from the measured z was less than expected according to Hubble's law. This result suggests that nearer galaxies are moving away from us relatively faster than those very distant ones, meaning the expansion of the universe in more recent epochs has sped up. This acceleration in the expansion of the universe (in place of the expected deceleration due to gravitational attraction between masses) seems to have begun roughly 5 billion years ago (8 to 9 Gyr after the Big Bang).

What could be causing the universe to accelerate in its expansion, against the attractive force of gravity? Does our understanding of gravity need to be revised? We don't know the answers to these questions; many scientists say dark energy is the biggest mystery facing science today. There are several speculations. But somehow it seems to have a long-range *repulsive* effect on matter, causing objects to speed away from each other ever faster. Whatever it is, it has been given the name dark energy.

One idea is a sort of quantum field given the name "quintessence." Another possibility suggests an energy latent in space itself (vacuum energy) and relates to an aspect of General Relativity known as the cosmological constant (symbol Λ). When Einstein developed his equations, he found that they offered no solutions for a static universe. In those days (1917) it was thought the universe was static—unchanging and everlasting. Einstein added an arbitrary constant to his equations to provide solutions for a static universe. A decade later, when Hubble showed us an expanding universe, Einstein discarded his cosmological constant as no longer needed $(\Lambda = 0)$. But now it is being reconsidered: perhaps Λ is not zero. Theoretical attempts to calculate Λ have so far given unreal values.

There is increasing evidence that the effects of some form of dark energy are very real. The data from the WMAP survey and other recent experiments agree well with theories and computer models when they input dark energy as providing 73% of the mass-energy in the universe, and when the total mass-energy density equals the critical density ρ_c .

Today's best estimate of how the mass-energy in the universe is distributed is as follows:

It is rea as stars and galaxies.

The idea that the universe is dominated by a completely unknown form of energy seems bizarre. Nonetheless, the exquisite agreement between theory and the measured CMB anisotropy observations plus other experimental data (clustering of galaxies-see next Section) appears to be meaningful.

Acceleration

Dark energy

Cosmological constant

FIGURE 33-27 Distribution of some 50,000 galaxies in a 2.5° slice through almost half of the sky above the equator, as measured by the Sloan Digital Sky Survey (SDSS). Each dot represents a galaxy. The distance from us is obtained from the redshift and Hubble's law, and is given in units of 10^9 light-years (Gly). At greater distances, fewer galaxies are bright enough to be detected, thus resulting in an apparent thinning out of galaxies. The point 0 represents us, our observation point. Note the "walls" and "voids" of galaxies.

33-9 Large-Scale Structure of the Universe

The beautiful WMAP pictures of the sky (Fig. 33–23 and Chapter opening photo) show small but significant inhomogeneities in the temperature of the CMB. These anisotropies reflect compressions and expansions in the primordial plasma just before decoupling, from which stars, galaxies, and clusters of galaxies formed. Analysis of the irregularities in WMAP by mammoth computer simulations predict the distribution of clusters of galaxies and superclusters of galaxies very similar to what is seen today (Fig. 33–27). These simulations are very successful if they contain dark energy and dark matter; and the dark matter needs to be cold (slow speed—think of Eq. 13-8, $\frac{1}{2}m\overline{v}^2 = \frac{3}{2}kT$ where T is temperature), rather than "hot" dark matter such as neutrinos which move at or very near the speed of light. Indeed, the modern cosmological model is called the Λ CDM model, where lambda (Λ) stands for the cosmological constant, and CDM is cold dark matter.

Cosmologists have gained substantial confidence in this cosmological model from such a precise fit between observations and theory. They can also extract very precise values for cosmological parameters which previously were only known with low accuracy. The CMB is such an important cosmological observable that every effort is being made to extract all of the information it contains. More space missions are being prepared to observe even finer details. They could provide experimental evidence for inflation, perhaps detecting gravity waves as predicted by inflation models (detectable by their effect on the CMB) and also provide information about elementary particle physics at energies far beyond the reach of man-made accelerators.

$33-10$ Finally ...

When we look up into the night sky, we see stars; and with the best telescopes, we see galaxies and the exotic objects we discussed earlier, including rare supernovae. But even with our best instruments we do not see the processes going on inside stars or supernovae that we hypothesized (and believe). We are dependent on brilliant theorists who come up with viable theories and ideas and verifiable models. We depend on complicated computer models whose parameters are varied until the outputs compare favorably with our observables and analyses of WMAP and other experiments. And we now have a surprisingly precise idea about some aspects of our universe: it is flat, it is 13.7 billion years old, it contains only 4% "normal" baryonic matter (for atoms), and so on. These precise results might suggest that we live at a very interesting time.

ACDM cosmological model

The questions raised by cosmology are difficult and profound, and may seem removed from everyday "reality." We can always say, "the Sun is shining, it's going to burn on for an unimaginably long time, all is well." Nonetheless, the questions of cosmology are deep ones that fascinate the human intellect. One aspect that is especially intriguing is this: calculations on the formation and evolution of the universe have been performed that deliberately varied the values—just slightly—of certain fundamental physical constants. The result? A universe in which life as we know it could not exist. [For example, if the difference in mass between proton and neutron were zero, or small (less than the mass of the electron, 0.511 MeV/ c^2), there would be no atoms: electrons would be captured by protons never to be freed again.] Such results have given rise to a philosophical idea called the Anthropic principle, which says that if the universe were even a little different than it is, we could not be here. It might even seem that the universe is exquisitely tuned, almost as if to accommodate us.

Anthropic principle

Summary

The night sky contains myriads of stars including those in the Milky Way, which is a "side view" of our Galaxy looking along the plane of the disc. Our Galaxy includes about 10^{11} stars. Bevond our Galaxy are billions of other galaxies.

Astronomical distances are measured in light-vears $(1 \text{ ly } \approx 10^{13} \text{ km})$. The nearest star is about 4 ly away and the nearest large galaxy is 2 million ly away. Our Galactic disc has a diameter of about 100,000 ly. Distances are often specified in **parsecs**, where 1 parsec = 3.26 ly.

Stars are believed to begin life as collapsing masses of hydrogen gas (protostars). As they contract, they heat up (potential energy is transformed to kinetic energy). When the temperature reaches about 10 million degrees, nuclear fusion begins and forms heavier elements (nucleosynthesis), mainly helium at first. The energy released during these reactions heats the gas so its outward pressure balances the inward gravitational force, and the young star stabilizes as a main-sequence star. The tremendous luminosity of stars comes from the energy released during these thermonuclear reactions. After billions of years, as helium is collected in the core and hydrogen is used up, the core contracts and heats further. The envelope expands and cools, and the star becomes a red giant (larger diameter, redder color). The next stage of stellar evolution depends on the mass of the star, which may have lost much of its original mass as its outer envelope escaped into space. Stars of residual mass less than about 1.4 solar masses cool further and become white dwarfs, eventually fading and going out altogether. Heavier stars contract further due to their greater gravity: the density approaches nuclear density, the huge pressure forces electrons to combine with protons to form neutrons, and the star becomes essentially a huge nucleus of neutrons. This is a neutron star, and the energy released from its final core collapse is believed to produce supernovae explosions. If the star is very massive, it may contract even further and form a black hole, which is so dense that no matter or light can escape from it.

In the general theory of relativity, the equivalence principle states that an observer cannot distinguish acceleration from a gravitational field. Said another way, gravitational and inertial masses are the same. The theory predicts gravitational bending of light rays to a degree consistent with experiment. Gravity is treated as a curvature in space and time, the curvature being greater near massive bodies. The universe as a whole may be curved. With sufficient mass, the curvature of the universe would be positive, and the universe is *closed* and finite; otherwise, it would be open and infinite.

Distant galaxies display a redshift in their spectral lines, interpreted as a Doppler shift. The universe seems to be expanding, its galaxies racing away from each other at speeds (v) proportional to the distance (d) between them:

$$
v = Hd. \tag{33-6}
$$

which is known as Hubble's law $(H$ is the Hubble parameter). This expansion of the universe suggests an explosive origin, the **Big Bang**, which occurred about 13.7 billion years ago.

The cosmological principle assumes that the universe, on a large scale, is homogeneous and isotropic.

Important evidence for the Big Bang model of the universe was the discovery of the cosmic microwave background radiation (CMB), which conforms to a blackbody radiation curve at a temperature of 2.725 K.

The standard model of the Big Bang provides a possible scenario as to how the universe developed as it expanded and cooled after the Big Bang. Starting at 10^{-43} seconds after the Big Bang, according to this model, there was a series of phase transitions during which previously unified forces of nature "condensed out" one by one. The inflationary scenario assumes that during one of these phase transitions, the universe underwent a brief but rapid exponential expansion. Until about 10^{-35} s, there was no distinction between quarks and leptons. Shortly thereafter, quarks were confined into hadrons (the hadron era). About 10^{-4} s after the Big Bang, the majority of hadrons disappeared, having combined with anti-hadrons, producing photons, leptons and energy, leaving mainly photons and leptons to freely move, thus introducing the lepton era. By the time the universe was about 10s old, the electrons too had mostly disappeared, having combined with their antiparticles; the universe was radiation-dominated. A couple of minutes later, nucleosynthesis began, but lasted only a few minutes.

It then took several hundred thousand years before the universe was cool enough for electrons to combine with nuclei to form atoms. The background radiation had expanded and cooled so much that its total energy became less than the energy in matter, and matter dominated increasingly over radiation. Then stars and galaxies formed, producing a universe not much different than it is todaysome 13 billion years later.

Questions

- 1. The Milky Way was once thought to be "murky" or "milky" but is now considered to be made up of point sources. Explain.
- 2. A star is in equilibrium when it radiates at its surface all the energy generated at its core. What happens when it begins to generate more energy than it radiates? Less energy? Explain.
- 3. Describe a red giant star. List some of its properties.
- 4. Select a point on the H-R diagram. Mark several directions away from this point. Now describe the changes that would take place in a star moving in each of these directions.
- 5. Does the H-R diagram reveal anything about the core of a star?
- 6. Why do some stars end up as white dwarfs, and others as neutron stars or black holes?
- 7. Can we tell, by looking at the population on the H-R diagram, that hotter main-sequence stars have shorter lives? Explain.
- 8. If you were measuring star parallaxes from the Moon instead of Earth, what corrections would you have to make? What changes would occur if you were measuring parallaxes from Mars?
- 9. Cepheid variable stars change in luminosity with a typical period of several days. The period has been found to have a definite relationship with the absolute luminosity of the star. How could these stars be used to measure the distance to galaxies?
- 10. What is a geodesic? What is its role in General Relativity?

Problems

33-1 to 33-3 Stars, Galaxies, Stellar Evolution, Distances

- 1. (I) Using the definitions of the parsec and the light-year, show that $1 pc = 3.26 ly.$
- 2. (I) A star exhibits a parallax of 0.38 seconds of arc. How far away is it?
- 3. (I) The parallax angle of a star is 0.00019° . How far away is the star?
- 4. (I) A star is 36 pc away. What is its parallax angle? State (a) in seconds of arc, and (b) in degrees.
- 5. (I) What is the parallax angle for a star that is 55 ly away? How many parsecs is this?
- 6. (I) If one star is twice as far away from us as a second star, will the parallax angle of the farther star be greater or less than that of the nearer star? By what factor?
- 7. (II) A star is 35 pc away. How long does it take for its light to reach us?

Recent observations indicate that the universe is flat, that it contains an as-yet unknown type of dark matter, and that it is dominated by a mysterious dark energy which exerts a sort of negative gravity causing the expansion of the universe to accelerate.

Today the evidence suggests that the universe is flat and will continue to expand indefinitely. The total contributions of baryonic (normal) matter, dark matter, and dark energy sum up to the critical density.

- 11. If it were discovered that the redshift of spectral lines of galaxies was due to something other than expansion, how might our view of the universe change? Would there be conflicting evidence? Discuss.
- 12. All galaxies appear to be moving away from us. Are we therefore at the center of the universe? Explain.
- 13. If you were located in a galaxy near the boundary of our observable universe, would galaxies in the direction of the Milky Way appear to be approaching you or receding from you? Explain.
- 14. Compare an explosion on Earth to the Big Bang. Consider such questions as: Would the debris spread at a higher speed for more distant particles, as in the Big Bang? Would the debris come to rest? What type of universe would this correspond to, open or closed?
- 15. If nothing, not even light, escapes from a black hole, then how can we tell if one is there?
- 16. What mass will give a Schwarzschild radius equal to that of the hydrogen atom in its ground state?
- 17. The Earth's age is often given as about 4 billion years. Find that time on Fig. 33-25. People have lived on Earth on the order of a million years. Where is that on Fig. 33-25?
- 18. Explain what the 2.7-K cosmic microwave background radiation is. Where does it come from? Why is its temperature now so low?
- 19. Why were atoms, as opposed to bare nuclei, unable to exist until hundreds of thousands of years after the Big Bang?
- 20. Under what circumstances would the universe eventually collapse in on itself?
- 8. (II) We saw earlier (Chapter 14) that the rate energy reaches the Earth from the Sun (the "solar constant") is about 1.3×10^3 W/m². What is (*a*) the apparent brightness l of the Sun, and (b) the absolute luminosity L of the Sun?
- 9. (II) What is the relative brightness of the Sun as seen from Jupiter as compared to its brightness from Earth? (Jupiter is 5.2 times farther from the Sun than the Earth.)
- 10. (II) Estimate the angular width that our Galaxy would subtend if observed from the nearest galaxy to us (Table 33-1). Compare to the angular width of the Moon from Earth.
- **11.** (II) When our Sun becomes a red giant, what will be its average density if it expands out to the orbit of Earth $(1.5 \times 10^{11} \text{ m from the Sun})$?
- 12. (II) When our Sun becomes a white dwarf, it is expected to be about the size of the Moon. What angular width will it subtend from the present distance to Earth?
- 13. (II) Calculate the density of a white dwarf whose mass is equal to the Sun's and whose radius is equal to the Earth's. How many times larger than Earth's density is this?
- 14. (II) A neutron star whose mass is 1.5 solar masses has a radius of about 11 km. Calculate its average density and compare to that for a white dwarf (Problem 13) and to that of nuclear matter.
- 15. (II) Calculate the Q -values for the He burning reactions of Eq. 33-2. (The mass of the very unstable ${}^{8}_{4}Be$ is 8.005305 u.)
- 16. (II) Suppose two stars of the same apparent brightness l are also believed to be the same size. The spectrum of one star peaks at 800 nm whereas that of the other peaks at 400 nm. Use Wien's law (Section 27-2) and the Stefan-Boltzmann equation (Eq. $14-5$) to estimate their relative distances from us. [*Hint*: see Examples $33-4$ and $33-5$.]
- 17. (III) Stars located in a certain cluster are assumed to be about the same distance from us. Two such stars have spectra that peak at $\lambda_1 = 500$ nm and $\lambda_2 = 700$ nm, and the ratio of their apparent brightness is $l_1/l_2 = 0.091$. Estimate their relative sizes (give ratio of their diameters). [*Hint*: use the Stefan-Boltzmann equation, Eq. 14-5.]

33-4 General Relativity, Gravity and Curved Space

- 18. (I) Show that the Schwarzschild radius for a star with mass equal to that (a) of our Sun is 2.95 km, and (b) of Earth is 8.9 mm.
- 19. (II) What is the Schwarzschild radius for a typical galaxy (like ours)?
- 20. (II) Describe a triangle, drawn on the surface of a sphere, for which the sum of the angles is (a) 359° , and $(b) 180^\circ$
- 21. (II) What is the maximum sum-of-the-angles for a triangle on a sphere?

General Problems

34. Suppose that three main-sequence stars could undergo the three changes represented by the three arrows, A, B, and C, in the H-R diagram of Fig. 33-28. For each case, describe the changes in temperature, luminosity, and size.

FIGURE 33-28 Problem 34.

33-5 Redshift, Hubble's Law

- 22. (I) If a galaxy is traveling away from us at 1.0% of the speed of light, roughly how far away is it?
- 23. (I) The redshift of a galaxy indicates a velocity of 3500 km/s. How far away is it?
- 24. (I) Estimate the speed of a galaxy (relative to us) that is near the observable "edge" of the universe, say 12 billion lightvears away.
- 25. (II) Estimate the observed wavelength for the 656-nm line in the Balmer series of hydrogen in the spectrum of a galaxy whose distance from us is (a) 1.0×10^6 ly, (b) 1.0×10^8 ly, (c) 1.0×10^{10} ly.
- 26. (II) Estimate the speed of a galaxy, and its distance from us, if the wavelength for the hydrogen line at 434 nm is measured on Earth as being 610 nm.
- 27. (II) What is the speed of a galaxy with $z = 0.60$?
- 28. (II) What would be the redshift parameter ζ for a galaxy traveling away from us at $v = 0.50c$?
- $29.$ (II) Starting from Eq. 33-3, show that the Doppler shift in wavelength is $\Delta \lambda / \lambda_0 \approx v/c$ (Eq. 33–5b) for $v \ll c$. [*Hint*: use the binomial expansion.]

33-6 to 33-8 The Big Bang, CMB, Universe Expansion

- 30. (I) Calculate the wavelength at the peak of the blackbody radiation distribution at 2.7 K using Wien's law.
- 31. (II) The critical density for closure of the universe is $\rho_c \approx 10^{-26}$ kg/m³. State ρ_c in terms of the average number of nucleons per cubic meter.
- 32. (II) The scale of the universe (the average distance between galaxies) at any one moment is believed to have been inversely proportional to the absolute temperature. Estimate the size of the universe, compared to today, at (a) $t = 10^6$ yr, (b) $t = 1$ s, (c) $t = 10^{-6}$ s, and (d) $t = 10^{-35}$ s.
- 33. (II) At approximately what time had the universe cooled below the threshold temperature for producing (a) kaons $(M \approx 500 \,\mathrm{MeV}/c^2)$, (b) Y $(M \approx 9500 \,\mathrm{MeV}/c^2)$, and (c) muons $(M \approx 100 \,\text{MeV}/c^2$?
- 35. Assume that the nearest stars to us have an absolute luminosity about the same as the Sun's. Their apparent brightness, however, is about 10^{11} times fainter than the Sun. From this, estimate the distance to the nearest stars. (Newton did this calculation, although he made a numerical error of a factor of 100.)
- 36. Use conservation of angular momentum to estimate the angular velocity of a neutron star which has collapsed to a diameter of 20 km, from a star whose radius was equal to that of our Sun $(7 \times 10^8 \text{ m})$, of mass 1.5 times that of the Sun, and which rotated (like our Sun) about once a month.
- 37. By what factor does the rotational kinetic energy change when the star in Problem 36 collapses to a neutron star?
- 38. A certain pulsar, believed to be a neutron star of mass 1.5 times that of the Sun, with diameter 20 km, is observed to have a rotation speed of $1.0 \, \text{rev/s}$. If it loses rotational kinetic energy at the rate of 1 part in $10⁹$ per day, which is all transformed into radiation, what is the power output of the star?
- 39. The nearest large galaxy to our Galaxy is about 2×10^6 ly away. If both galaxies have a mass of 3×10^{41} kg, with what gravitational force does each galaxy attract the other?
- $40.$ Estimate what neutrino rest mass (in eV) would provide the critical density to close the universe. Assume the neutrino density is, like photons, about $10⁹$ times that of nucleons, and that nucleons make up only (a) 2% of the mass needed, or (b) 5% of the mass needed.
- 41. Two stars, whose spectra peak at 600 nm and 400 nm, respectively, both lie on the main sequence. Use Wien's law, the Stefan-Boltzmann equation, and the H-R diagram (Fig. 33-6) to estimate the ratio of their diameters. [*Hint*: see Examples 33-4 and 33-5.]
- 42. Suppose we can measure distances with parallax at 100 parsecs. What is our minimum angular resolution (in degrees), based on this information?
- 43. Through some coincidence, the Balmer lines from singly ionized helium in a distant star happen to overlap with the Balmer lines from hydrogen (Fig. $27-22$) in the Sun. How fast is the star receding from us?
- 44. What is the temperature that corresponds to 1.8-TeV collisions at the Fermilab collider? To what era in cosmological history does this correspond? [Hint: see Fig. 33-25.]
- 45. Astronomers have recently measured the rotation of gas around what might be a supermassive black hole of about 2 billion solar masses at the center of a galaxy. If the radius from the galactic center to the gas clouds is 60 light-years, what Doppler shift $\Delta\lambda/\lambda_0$ do you estimate they saw?
- 46. A galaxy is moving away from Earth. The "blue" hydrogen line at 434 nm emitted from the galaxy is measured on Earth to be 650 nm . (a) How fast is the galaxy moving? (b) How far is it from Earth?
- 47. In the later stages of stellar evolution, a star (if massive enough) will begin fusing carbon nuclei to form, for example, magnesium:

 $^{12}_{6}C + ^{12}_{6}C \rightarrow ^{24}_{12}Mg + \gamma.$

 (a) How much energy is released in this reaction (see Appendix B). (b) How much kinetic energy must each carbon nucleus have (assume equal) in a head-on collision if they are just to touch (use Eq. $30-1$) so that the strong force can come into play? (c) What temperature does this kinetic energy correspond to?

48. Consider the reaction

$$
^{16}_{8}O + ^{16}_{8}O \rightarrow ^{28}_{14}Si + ^{4}_{2}He,
$$

and answer the same questions as in Problem 47.

49. How large would the Sun be if its density equaled the critical density of the universe, $\rho_c \approx 10^{-26} \text{ kg/m}^3$? Express your answer in light-years and compare with the Earth-Sun distance and the size of our Galaxy.

Answers to Exercises

- A: Ourselves; 2 years ago.
- **B:** 600 ly (estimating L from Fig. 33–6 as $L \approx 8 \times 10^{26}$ W; note that on a log scale, 6000 K is closer to 7000 K than it is to 5000 K).
- $C: 1.4.$

Mathematical Review

A-1 Relationships, Proportionality, and Equations

One of the important aspects of physics is the search for relationships between different quantities—that is, determining how one quantity affects another. For example, how does temperature affect the air pressure in a tire? Or how does the net force on an object affect its acceleration? Sometimes a given quantity is affected by two or more quantities; for instance, the acceleration of an object is related to both its mass and the applied force. If you suspect that a relationship exists between two or more quantities, you can try to determine the precise nature of this relationship. This is done by varying one of the quantities and measuring how the other varies as a result. If it is likely that a particular quantity will be affected by more than one factor or quantity, only one quantity is varied at a time, while the others are held constant.[†]

As a simple example, the ancients found that if one circle has twice the diameter of a second circle, the first also has twice the circumference. If the diameter is three times as large, the circumference is also three times as large. In other words, an increase in the diameter results in a proportional increase in the circumference. We say that the circumference is *directly proportional to* the diameter. This can be written in symbols as $C \propto D$, where " \propto " means "is proportional to," and C and D refer to the circumference and diameter of a circle, respectively. The next step is to change this proportionality to an equation, which will make it possible to link the two quantities numerically. This merely entails inserting a proportionality constant, which in many cases is determined by measurement. (In some cases it can be chosen arbitrarily, if it involves only the definition of a new unit.) The ancients found that the ratio of the circumference to the diameter of any circle was 3.1416 (to keep only the first few decimal places). This number is designated by the Greek letter π . It is the constant of proportionality for the relationship $C \propto D$. To obtain an equation, we insert π into the proportion and change the α to =. Thus, $C = \pi D$.

Other kinds of proportionality occur as well. For example, the area of a circle is proportional to the *square* of its radius. That is, if the radius is doubled, the area becomes four times as large; and so on. In this case we can write $A \propto r^2$, where A stands for the area and r for the radius of the circle.

Sometimes two quantities are related in such a way that an increase in one leads to a proportional *decrease* in the other. This is called *inverse proportion*. For example, the time required to travel a given distance is inversely proportional to the speed of travel. The greater the speed, the less time it takes. We can write this inverse proportion as time $\propto 1$ /speed. The larger the denominator of a fraction, the lower the value of the fraction is as a whole. For example, $\frac{1}{4}$ is less than $\frac{1}{2}$. Thus, if the speed is doubled, the time is halved, which is what we want to express by this inverse proportionality relationship.

[†]When one quantity affects another, we often use the expression "is a function of" to indicate this dependence; for example, we say that the pressure in a tire is a function of the temperature.

Direct proportion

Inverse proportion

Whatever kind of proportion is found to hold, it can be changed to an equality by insertion of the proper proportionality constant. Quantitative statements or predictions about the physical world can then be made with the equation.

2 Exponents

When we write $10⁴$, we mean that you multiply 10 by itself four times: $10^4 = 10 \times 10 \times 10 \times 10 = 10,000$. The superscript 4 is called an *exponent*, and 10 is said to be raised to the fourth power. Any number or symbol can be raised to a power; special names are used when the exponent is 2 (a^2 is "*a* squared") or 3 (a^3 is "a cubed"). For any other power, we say a^n is "a to the nth power." If the exponent is 1, it is usually dropped: $a^1 = a$, since no multiplication is involved.

The rules for multiplying numbers expressed as powers are as follows:

$$
a^n(a)^n = a^{n+m}.\tag{A-1}
$$

That is, the exponents are added. To see why, consider the result of the multiplication of $3³$ by $3⁴$:

$$
(3^3)(3^4) = (3)(3)(3) \times (3)(3)(3)(3) = (3)^7
$$

Here the sum of the exponents is $3 + 4 = 7$, so rule A-1 works. Notice that this rule works only if the base numbers (a in Eq. A-1) are the same. Thus we *cannot* use the rule of summing exponents for $(6^3)(5^2)$; these numbers would have to be written out. However, if the base numbers are different but the exponents are the same, we can write a second rule:

$$
(an)(bn) = (ab)n.
$$
\n
$$
(an)(cn) = (2c)n.
$$
\n
$$
(an) = (ab)n.
$$

For example, $(5^3)(6^3) = (30)^3$ since

$$
(5)(5)(5)(6)(6)(6) = (30)(30)(30).
$$

The third rule involves a power raised to another power: $(a^3)^2$ means $(a^3)(a^3)$, which is equal to $a^{3+3} = a^6$. The general rule is then

$$
(a^n)^m = a^{nm}.\tag{A-3}
$$

In this case, the exponents are multiplied.

Negative exponents are used for reciprocals. Thus,

$$
\frac{1}{a} = a^{-1}, \qquad \frac{1}{a^3} = a^{-3},
$$

and so on. The reason for using negative exponents is to allow us to use the multiplication rules given above. For example, $(a^{5})(a^{-3})$ means

$$
\frac{(a)(a)(a)(a)(a)}{(a)(a)(a)} = a^2
$$

Rule A-1 gives us the same result:

$$
(a^5)(a^{-3}) = a^{5-3} = a^2.
$$

What does an exponent of zero mean? That is, what is a^{0} ? Any number raised to the zeroth power is defined as being equal to 1:

$$
a^0=1.
$$

This definition is used because it follows from the rules for adding exponents. For example,

$$
a^3a^{-3} = a^{3-3} = a^0 = 1.
$$

But *does* a^3a^{-3} actually equal 1? Yes, because

$$
a^3a^{-3} = \frac{a^3}{a^3} = 1.
$$

Fractional exponents are used to represent *roots*. For example, $a^{\frac{1}{2}}$ means the square root of a; that is, $a^{\frac{1}{2}} = \sqrt{a}$. Similarly, $a^{\frac{1}{3}}$ means the cube root of a, and so on. The fourth root of a means that if you multiply the fourth root of a by itself four times, you again get a :

$$
(a^{\frac{1}{4}})^4 = a.
$$

This is consistent with rule A-3 since $(a^{\frac{1}{4}})^4 = a^{\frac{4}{4}} = a^1 = a$.

A-3 Powers of 10, or Exponential Notation

Writing out very large and very small numbers such as the distance of Neptune from the Sun, 4,500,000,000 km, or the diameter of a typical atom, 0.00000001 cm, is inconvenient and prone to error. It also leaves in question (see Section $1-4$) the number of significant figures. (How many of the zeros are significant in the number 4,500,000,000 km?) We therefore make use of the "powers of 10," or exponential notation. The distance from Neptune to the Sun is then expressed as 4.50×10^9 km (assuming that the value is significant to three digits), and the diameter of an atom 1.0×10^{-8} cm. This way of writing numbers is based on the use of exponents, where $aⁿ$ signifies a multiplied by itself *n* times. For example, $10^4 = 10 \times 10 \times 10 \times 10 = 10,000$. Thus, $4.50 \times 10^9 = 4.50 \times 1,000,000,000 = 4,500,000,000$. Notice that the exponent (9 in this case) is just the number of places the decimal point is moved to the right to obtain the fully written-out number (4.500,000,000.)

When two numbers are multiplied (or divided), you first multiply (or divide) the simple parts and then the powers of 10. Thus, 2.0 \times 10³ multiplied by 5.5 \times 10⁴ equals $(2.0 \times 5.5) \times (10^3 \times 10^4) = 11 \times 10^7$, where we have used the rule for adding exponents (Appendix A–2). Similarly, 8.2 \times 10⁵ divided by 2.0 \times 10² equals

$$
\frac{8.2 \times 10^5}{2.0 \times 10^2} = \frac{8.2}{2.0} \times \frac{10^5}{10^2} = 4.1 \times 10^3.
$$

For numbers less than 1, say 0.01, the exponent power of 10 is written with a negative sign: $0.01 = 1/100 = 1/10^2 = 1 \times 10^{-2}$. Similarly, $0.002 = 2 \times 10^{-3}$. The decimal point has again been moved the number of places expressed in the exponent. Thus, $0.020 \times 3600 = 72$; in exponential notation $(2.0 \times 10^{-2}) \times (3.6 \times 10^{3}) = 7.2 \times 10^{1} = 72.$

Notice also that $10^1 \times 10^{-1} = 10 \times 0.1 = 1$, and by the law of exponents, $10^1 \times 10^{-1} = 10^0$. Therefore, $10^0 = 1$.

When writing a number in exponential notation, it is usual to make the simple number be between 1 and 10. Thus it is conventional to write 4.5×10^9 rather than 45×10^8 , although they are the same number.[†] This notation also allows the number of *significant figures* to be clearly expressed. We write 4.50×10^9 if this value is accurate to three significant figures, but 4.5×10^9 if it is accurate to only two.

4 Algebra

Physical relationships between quantities can be represented as equations involving symbols (usually letters of the alphabet) that represent the quantities. The manipulation of such equations is the field of algebra, and it is used a great deal in physics. An equation involves an equals sign, which tells us that the quantities on either side of the equals sign have the same value. Examples of equations are

$$
3 + 8 = 11
$$

$$
2x + 7 = 15
$$

$$
a2b + c = 6.
$$

The first equation involves only numbers, so is called an arithmetic equation. The other two equations are algebraic since they involve symbols. In the third equation, the quantity a^2b means the product of a times a times b: $a^2b = a \times a \times b$.

[†]Another convention used, particularly with computers, is that the simple number be between 0.1 and 1. Thus we could write 4,500,000,000 as 0.450×10^{10} .

Solving for an Unknown

Often we wish to solve for one (or more) symbols, and we treat it as an *unknown*. For example, in the equation $2x + 7 = 15$, x is the unknown; this equation is true, however, only when $x = 4$. Determining what value (or values) the unknown(s) can have to satisfy the equation(s) is called *solving the* equation. To solve an equation, the following rule can be used:

An equation will remain true if any operation performed on one side is also *performed on the other side:* for example, (a) addition or subtraction of a number or symbol; (b) multiplication or division by a number or symbol; (c) raising each side of the equation to the same power, or taking the same root (such as square root).

EXAMPLE A-1 Solve for x in the equation

 $2x + 7 = 15$.

APPROACH We perform the same operations on both sides of the equation to isolate x as the only variable on the left side of the equals sign.

SOLUTION We first subtract 7 from both sides:

$$
2x + 7 - 7 = 15 - 7
$$

or

 $2x = 8$.

Then we divide both sides by 2 to get

$$
\frac{2x}{2} = \frac{8}{2}
$$

or, carrying out the divisions,

 $x=4$

and this solves the equation.

EXAMPLE A-2 (*a*) Solve the equation

$$
a^2b + c = 24
$$

for the unknown a in terms of b and c. (b) Solve for a assuming that $b = 2$ and $c = 6$.

APPROACH We perform operations to isolate a as the only variable on the left side of the equals sign.

SOLUTION (a) We are trying to solve for a, so we first subtract c from both sides:

 $a^2b = 24 - c$,

then divide by b:

$$
a^2 = \frac{24-c}{b},
$$

and finally take square roots:

$$
a = \sqrt{\frac{24 - c}{b}}.
$$

(b) If we are given that $b = 2$ and $c = 6$, then

$$
a = \sqrt{\frac{24 - 6}{2}} = 3.
$$

NOTE Whenever we take a square root, the number can be either positive or negative. Thus $a = -3$ is also a solution. Why? Because $(-3)^2 = 9$, just as $(+3)^2 = 9$. So we actually get two solutions: $a = +3$ and $a = -3$.

To check a solution, we put it back into the original equation (this is really a check that we did all the manipulations correctly). In the equation

$$
a^2b + c = 24,
$$

we put in $a = 3$, $b = 2$, $c = 6$ and find

$$
(3)^{2}(2) + (6) \stackrel{?}{=} 24
$$

24 = 24,

which checks.

EXERCISE A Put $a = -3$ into the equation of Example A-2 and show that it works too.

Two or More Unknowns

If we have two or more unknowns, one equation is not sufficient to find them. In general, if there are n unknowns, n independent equations are needed. For example, if there are two unknowns, we need two equations. If the unknowns are called x and y , a typical procedure is to solve one equation for x in terms of y, and substitute this into the second equation.

EXAMPLE A-3 Solve the following pair of equations for x and y.

$$
3x - 2y = 19
$$

$$
x + 4y = -3.
$$

APPROACH We have two unknowns and two equations; we can start by solving the second equation for x in terms of y . Then we substitute this result for x into the first equation.

SOLUTION We subtract 4y from both sides of the second equation:

 $x = -3 - 4y$.

We substitute this expression for x into the first equation, and simplify:

$$
3(-3-4y) - 2y = 19
$$

\n
$$
-9 - 12y - 2y = 19
$$
 (carried out the multiplication by 3)
\n
$$
-14y = 28
$$
 (added 9 to both sides)
\n
$$
y = -2.
$$
 (divided both sides by -14)

Now that we know $y = -2$, we substitute this into the expression for x:

 $x = -3 - 4y$ $= -3 - 4(-2) = -3 + 8 = 5.$

Our solution is $x = 5$, $y = -2$. We check this solution by putting these values back into the original equations:

$$
3x - 2y \stackrel{?}{=} 19
$$

3(5) - 2(-2) $\stackrel{?}{=} 19$
15 + 4 $\stackrel{?}{=} 19$
19 = 19 (it checks)
 $x + 4y \stackrel{?}{=} -3$

and

$$
x + 4y \stackrel{?}{=} -3
$$

5 + 4(-2) $\stackrel{?}{=} -3$
-3 = -3. (it checks)

Other methods for solving two or more equations, such as the method of determinants, can be found in an algebra textbook.

The Quadratic Formula

We sometimes encounter equations that involve an unknown, say x , that appears not only to the first power, but squared as well. Such a quadratic equation can be written in the form

$$
ax^2 + bx + c = 0.
$$

The quantities a, b, and c are typically numbers or constants that are given.[†] The general solutions to such an equation are given by the *quadratic formula*:

Quadratic formula

$$
x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}.
$$
 (A-4)

The \pm sign indicates that there are two solutions for x; one where the plus sign is used, the other where the minus sign is used.

EXAMPLE A-4 Find the solutions for
$$
x
$$
 in the equation

 $3x^2 - 5x = 2$.

APPROACH Here x appears both to the first power and squared, so we use the quadratic equation.

SOLUTION First we write this equation in the standard form

 $ax^2 + bx + c = 0$

by subtracting 2 from both sides:

 $3x^2 - 5x - 2 = 0.$

In this case, a, b, and c in the standard formula take the values $a = 3$, $b = -5$, and $c = -2$. The two solutions for x are

> $x = \frac{+5 + \sqrt{25 - (4)(3)(-2)}}{(2)(3)} = \frac{5 + 7}{6} = 2$ $+5 = \sqrt{25 - (4\sqrt{21} - 2)}$

and

$$
x = \frac{+5 - \sqrt{25 - (4)(3)(-2)}}{(2)(3)} = \frac{5 - 7}{6} = -\frac{1}{3}.
$$

In this Example, the two solutions are $x = 2$ and $x = -\frac{1}{3}$. In physics problems, it sometimes happens that only one of the solutions corresponds to a real-life situation; in this case, the other solution is discarded. In other cases, both solutions may correspond to physical reality.

Notice, incidentally, that b^2 must be greater than 4*ac*, so that $\sqrt{b^2 - 4ac}$ yields a real number. If $(b^2 - 4ac)$ is less than zero (negative), there is no real solution. The square root of a negative number is called *imaginary*.

A second-order equation—one in which the highest power of x is 2—has two solutions; a third-order equation—involving x^3 —has three solutions; and so on.

5 The Binomial Expansion

Sometimes we end up with a quantity of the form $(1 + x)^n$. That is, the quantity $(1 + x)$ is raised to the *n*th power. This can be written as an infinite sum of terms, known as a series expansion, as follows:

$$
(1+x)^n = 1 + nx + \frac{n(n-1)}{2!}x^2 + \cdots
$$
 (A-5)

This formula is useful for us mainly when x is very small compared to one $(x \ll 1)$. In this case, each successive term is much smaller than the preceding

[†]Or one or more of them could be variables, in which case additional equations are needed.

term. For example, if $x = 0.01$, and $n = 2$, say, then whereas the first term equals 1, the second term is $nx = (2)(0.01) = 0.02$, and the third term is $[(2)(1)/2](0.01)^2 = 0.0001$, and so on. Thus, when x is small, we can ignore all but the first two (or three) terms and can write

$$
(1+x)^n \approx 1 + nx. \tag{A-6}
$$

This approximation often allows us to solve an equation easily that otherwise might be very difficult. Some examples are

$$
(1 + x)^2 \approx 1 + 2x,
$$

\n
$$
\frac{1}{1 + x} = (1 + x)^{-1} \approx 1 - x,
$$

\n
$$
\sqrt{1 + x} = (1 + x)^{\frac{1}{2}} \approx 1 + \frac{1}{2}x,
$$

\n
$$
\frac{1}{\sqrt{1 + x}} = (1 + x)^{-\frac{1}{2}} \approx 1 - \frac{1}{2}x,
$$

where $x \ll 1$.

As a numerical example, let us evaluate $\sqrt{1.02}$ using the binomial expansion since $x = 0.02$ is much smaller than 1:

$$
\sqrt{1.02} = (1.02)^{\frac{1}{2}} = (1 + 0.02)^{\frac{1}{2}} \approx 1 + \frac{1}{2}(0.02) = 1.01.
$$

You can check with a calculator (and maybe not even more quickly) that $\sqrt{1.02} \approx 1.01$.

6 Plane Geometry

We review here a number of theorems involving angles and triangles that are useful in physics.

- 1. Equal angles. Two angles are equal if any of the following conditions are true: (a) They are vertical angles (Fig. A–1); or
	- (b) the left side of one is parallel to the left side of the other, and the right side of one is parallel to the right side of the other (the left and right sides are as seen from the vertex, where the two sides meet; Fig. $A-2$); or
	- (c) the left side of one is perpendicular to the left side of the other, and the right sides are likewise perpendicular (Fig. $A-3$).
- 2. The sum of the angles in any plane triangle is 180°.
- 3. Similar triangles. Two triangles are said to be similar if all three of their angles are equal (in Fig. A-4, $\theta_1 = \phi_1$, $\theta_2 = \phi_2$, and $\theta_3 = \phi_3$). Similar triangles thus have the same basic shape but may be different sizes and have different orientations. Two useful theorems about similar triangles are:
	- (a) Two triangles are similar if any two of their angles are equal. (This follows because the third angles must also be equal since the sum of the angles of a triangle is 180° .)
	- (b) The ratios of corresponding sides of two similar triangles are equal. That is (Fig. A-4),

$$
\frac{a_1}{b_1} = \frac{a_2}{b_2} = \frac{a_3}{b_3}
$$

- 4. Congruent triangles. Two triangles are congruent if one can be placed precisely on top of the other. That is, they are similar triangles and they have the same size. Two triangles are congruent if any of the following holds: (a) The three corresponding sides are equal.
	- (b) Two sides and the enclosed angle are equal ("side-angle-side").
	- (c) Two angles and the enclosed side are equal ("angle-side-angle").

 θ

- 5. Right triangles. A right triangle has one angle that is 90° (a right angle); that is, the two sides that meet at the right angle are perpendicular (Fig. $A-5$). The two other (acute) angles in the right triangle add up to 90°.
- 6. Pythagorean theorem. In any right triangle, the square of the length of the hypotenuse (the side opposite the right angle) is equal to the sum of the squares of the lengths of the other two sides. In Fig. $A-5$,

 $c^2 = a^2 + b^2$.

7 Trigonometric Functions and Identities

Trigonometric functions for any angle θ are defined by constructing a right triangle about that angle as shown in Fig. A–6; opp and adj are the lengths of the sides opposite and adjacent to the angle θ , and hyp is the length of the hypotenuse:

Figure A-7 shows the signs $(+)$ or $-)$ that cosine, sine, and tangent take on for angles θ in the four quadrants (0° to 360°). Note that angles are measured counterclockwise from the x axis as shown; negative angles are measured from below the x axis, clockwise: for example, $-30^{\circ} = +330^{\circ}$, and so on.

The following are some useful identities among the trigonometric functions:

$$
\sin^2 \theta + \cos^2 \theta = 1
$$

\n
$$
\sin 2\theta = 2 \sin \theta \cos \theta
$$

\n
$$
\cos 2\theta = \cos^2 \theta - \sin^2 \theta = 2 \cos^2 \theta - 1 = 1 - 2 \sin^2 \theta
$$

\n
$$
\tan 2\theta = \frac{2 \tan \theta}{1 - \tan^2 \theta}
$$

\n
$$
\sin(A \pm B) = \sin A \cos B \pm \cos A \sin B
$$

\n
$$
\cos(A \pm B) = \cos A \cos B \mp \sin A \sin B
$$

\n
$$
\tan(A \pm B) = \frac{\tan A \pm \tan B}{1 \mp \tan A \tan B}
$$

\n
$$
\sin(180^\circ - \theta) = \sin \theta
$$

\n
$$
\cos(180^\circ - \theta) = \cos \theta
$$

\n
$$
\cos(90^\circ - \theta) = \sin \theta
$$

\n
$$
\sin \frac{1}{2}\theta = \sqrt{\frac{1 - \cos \theta}{2}}
$$

\n
$$
\cos \frac{1}{2}\theta = \sqrt{\frac{1 + \cos \theta}{2}}
$$

\n
$$
\tan \frac{1}{2}\theta = \sqrt{\frac{1 - \cos \theta}{2}}
$$

\n
$$
\sin A \pm \sin B = 2 \sin \left(\frac{A \pm B}{2}\right) \cos \left(\frac{A \mp B}{2}\right).
$$

\n
$$
\sin \frac{\sin \alpha}{a} = \frac{\sin \beta}{b} = \frac{\sin \gamma}{c}
$$
 (law of sines)
\n
$$
\frac{\sin \alpha}{a} = \frac{\sin \beta}{b} = \frac{\sin \gamma}{c}
$$
 (law of sines)

Trigonometric Table: Numerical Values of Sin, Cos, Tan

SECTION A-7 Trigonometric Functions and Identities A-9

Logarithms are defined in the following way:

if
$$
y = A^x
$$
, then $x = \log_A y$.

That is, the logarithm of a number y to the base A is that number which, as the Common logs exponent of A , gives back the number y . For *common logarithms*, the base $is 10, so$

if
$$
y = 10^x
$$
, then $x = \log y$

Natural logs

The subscript 10 on log_{10} is usually omitted when dealing with common logs. Another base sometimes used is the exponential base $e = 2.718 \dots$, a natural number.[†] Such logarithms are called *natural logarithms* and are written ln. Thus,

if $y = e^x$, then $x = \ln y$.

For any number y, the two types of logarithm are related by

$$
\ln y = 2.3026 \log y
$$
.

Some simple rules for logarithms are as follows:

$$
\log(ab) = \log a + \log b. \tag{A-7}
$$

This is true because if $a = 10^n$ and $b = 10^m$, then $ab = 10^{n+m}$. From the definition of logarithm, $\log a = n$, $\log b = m$, and $\log (ab) = n + m$; hence, $log (ab) = n + m = log a + log b$. In a similar way, we can show that

$$
\log\left(\frac{a}{b}\right) = \log a - \log b \tag{A-8}
$$

and

$$
\log a^n = n \log a. \tag{A-9}
$$

These three rules apply not only to common logs but to natural or any other kind of logarithm.

Logs were once used as a technique for simplifying certain types of calculation. Because of the advent of electronic calculators and computers, they are not often used any more for this purpose. However, logs do appear in certain physical equations, so it is helpful to know how to deal with them. If you do not have a calculator that calculates logs, you can easily use a log *table*, such as the small one shown here (Table $A-1$). The number N is given to two digits (some tables give N to three or more digits); the first digit is in the vertical column to the left, the second digit is in the horizontal row across the top. For example, the Table tells us that $log 1.0 = 0.000$, $log 1.1 = 0.041$, and $log 4.1 = 0.613$. Table A-1 does not include the decimal point—it is understood. The Table gives logs for numbers between 1.0 and 9.9; for larger or smaller numbers, we use rule A-7:

$$
\log(ab) = \log a + \log b.
$$

For example,

 $log(380) = log(3.8 \times 10^2) = log(3.8) + log(10^2).$

From the Table, $log 3.8 = 0.580$; and from rule A-9,

 $\log{(10^2)} = 2 \log{(10)} = 2,$

since $log(10) = 1$. [This follows from the definition of the logarithm: if

^{\dagger}The exponential base e can be written as an infinite series:

$$
e = 1 + \frac{1}{1} + \frac{1}{1 \cdot 2} + \frac{1}{1 \cdot 2 \cdot 3} + \frac{1}{1 \cdot 2 \cdot 3 \cdot 4} + \cdots
$$

 $10 = 10¹$, then $1 = \log(10)$. Thus,

$$
log (380) = log (3.8) + log (102)
$$

= 0.580 + 2
= 2.580.

Similarly,

$$
log (0.081) = log (8.1) + log (10-2)
$$

= 0.908 - 2 = -1.092.

Sometimes we need to do the reverse process: find the number N whose log is, say, 2.670. This is called "taking the antilogarithm." To do so, we separate our Antilogs number 2.670 into two parts, making the separation at the decimal point:

> $log N = 2.670 = 2 + 0.670$ $=$ log $10^2 + 0.670$.

We now look at Table $A-1$ to see what number has its log equal to 0.670; none does, so we must *interpolate*: we see that $log 4.6 = 0.663$ and $log 4.7 = 0.672$. So the number we want is between 4.6 and 4.7, and closer to the latter by $\frac{7}{9}$. Approximately we can say that $log 4.68 = 0.670$. Thus

$$
\log N = 2 + 0.670
$$

= $\log (10^2) + \log (4.68) = \log (4.68 \times 10^2)$,

so $N = 4.68 \times 10^2 = 468$.

If the given logarithm is negative, say, -2.180 , we proceed as follows:

$$
\log N = -2.180 = -3 + 0.820
$$

= $\log 10^{-3} + \log 6.6 = \log 6.6 \times 10^{-3}$,

so $N = 6.6 \times 10^{-3}$. Notice that we added to our given logarithm the next largest integer (3 in this case) so that we have an integer, plus a decimal number between 0 and 1.0 whose antilogarithm can be looked up in the Table.

Rotating Frames of Reference; Inertial Forces; Coriolis Effect

Inertial and Noninertial Reference Frames

In Chapters 5 and 8 we examined the motion of objects, including circular and rotational motion, from the outside, as observers fixed on the Earth. Sometimes it is convenient to place ourselves (in theory, if not physically) into a reference frame that is rotating. Let us examine the motion of objects from the point of view, or frame of reference, of persons seated on a rotating platform such as a merry-go-round. It looks to them as if the rest of the world is going around *them*. But let us focus on what they observe when they place a tennis ball on the floor of the rotating platform, which we assume is frictionless. If they put the ball down gently, without giving it any push, they will observe that it accelerates from rest and moves outward as shown in Fig. C-1a. According to Newton's first law, an object initially at rest should stay at rest if no force

FIGURE C-1 Path of a ball released on a rotating merry-goround as seen (a) in the reference frame of the merry-go-round, and (b) in a reference frame fixed on the ground.

acts on it. But, according to the observers on the rotating platform, the ball starts moving even though there is no force applied to it. To observers on the ground, this is all very clear: the ball has an initial velocity when it is released (because the platform is moving), and it simply continues moving in a straight-line path as shown in Fig. $C-1b$, in accordance with Newton's first law.

But what shall we do about the frame of reference of the observers on the rotating platform? Clearly, Newton's first law, the law of inertia, does not hold in this rotating frame of reference. For this reason, such a frame is called a noninertial reference frame. An inertial reference frame (as discussed in Chapter 4) is one in which the law of inertia—Newton's first law—does hold, and so do Newton's second and third laws. In a noninertial reference frame, such as our rotating platform, Newton's second law also does not hold. For instance in the situation described above, there is no net force on the ball; yet, with respect to the rotating platform, the ball accelerates.

Fictitious (Inertial) Forces

Because Newton's laws do not hold when observations are made with respect to a rotating frame of reference, calculation of motion can be complicated. However, we can still apply Newton's laws in such a reference frame if we make use of a trick. The ball on the rotating platform of Fig. C-1a flies outward when released (as if a force were acting on it—though as we saw above, no force actually does act on it); so the trick we use is to write down the equation $\Sigma F = ma$ as if a force equal to mv^2/r (or $m\omega^2r$) were acting radially outward on the object in addition to any other forces that may be acting. This extra force, which might be designated as "centrifugal force" since it seems to act outward, is called a fictitious force or pseudoforce. It is a pseudoforce ("pseudo" means "false") because there is no object that exerts this force. Furthermore, when viewed from an inertial reference frame, the effect doesn't exist at all. We have made up this pseudoforce so that we can make calculations in a noninertial frame using Newton's second law, $\Sigma F = ma$. Thus the observer in the noninertial frame of Fig. C-1a uses Newton's second law for the ball's outward motion by assuming that a force equal to mv^2/r acts on it. Such pseudoforces are also called **inertial forces** since they arise only because the reference frame is not an inertial one.

We can examine the motion of a particle in a centrifuge (Section $5-5$) from the frame of reference of the rotating test tube. In this frame of reference, the particles move in a more-or-less straight path down the tube. (From the reference frame of the Earth, the particles go round and round.) The acceleration of a particle with respect to the rotating tube can then be calculated using $F = ma$ if we include a pseudoforce, "F," equal to $m\omega^2r = m(v^2/r)$ acting down the tube, in addition to the drag force F_D exerted by the fluid on the particle (Fig. C-2) up the tube.

In Section 5-3 we discussed the forces on a person in a car going around a curve (Fig. $5-11$) from the point of view of an inertial frame. The car, on the other hand, is not an inertial frame. Passengers in such a car could interpret this being pressed outward as the effect of a "centrifugal" force. But they need to recognize that it is a pseudoforce because there is no identifiable object exerting it. It is an effect of being in a noninertial frame of reference.

The Earth itself is rotating on its axis. Thus, strictly speaking, Newton's laws are not valid on the Earth. However, the effect of the Earth's rotation is usually so small that it can be ignored, although it does influence the movement of large air masses and ocean currents. Because of the Earth's rotation, the material of the Earth is concentrated slightly more at the equator. The Earth is thus not a perfect sphere but is slightly fatter at the equator than at the poles.

Fictitious force (pseudoforce)

Inertial force

FIGURE C-2 The forces on a particle in a test tube rotating in a centrifuge, seen in the reference frame of the test tube.

Coriolis Effect

In a reference frame that rotates at a constant angular speed ω (relative to an inertial frame), there exists another pseudoforce known as the Coriolis force. It appears to act on a body in a rotating reference frame only if the body is moving relative to that reference frame, and it acts to deflect the body sideways. It, too, is an effect of the reference frame being noninertial and hence is referred to as an *inertial force*. To see how the Coriolis force arises, consider two people, A and B, at rest on a platform rotating with angular speed ω , as shown in Fig. C-3a. They are situated at distances r_A and r_B , respectively, from the axis of rotation (at O). The woman at A throws a ball with a horizontal velocity \vec{v} (in her reference frame) radially outward toward the man at B on the outer edge of the platform. In Fig. $C-3a$, we view the situation from an inertial reference frame. The ball initially has not only the velocity \vec{v} radially outward, but also a tangential velocity \vec{v}_A due to the rotation of the platform. Now Eq. 8–4 tells us that $v_A = r_A \omega$, where r_A is the woman's radial distance from the axis of rotation at O. If the man at B had this same velocity v_A , the ball would reach him perfectly. But his speed is greater than v_A (Fig. C-3a) since he is farther from the axis of rotation. His speed is $v_{\rm B} = r_{\rm B}\omega$, which is greater than $v_{\rm A}$ because $r_{\rm B} > r_{\rm A}$. Thus, when the ball reaches the outer edge of the platform, it passes a point that the man at B has already passed because his speed in that direction is greater than the ball's. So the ball passes behind him.

Figure C-3b shows the situation as seen from the rotating platform as frame of reference. Both A and B are at rest, and the ball is thrown with velocity \vec{v} toward B, but the ball deflects to the right as shown and passes behind B as previously described. This is not a centrifugal-force effect, for the latter acts radially outward. Instead, this effect acts sideways, perpendicular to \vec{v} , and is called a **Coriolis acceleration**; it is said to be due to the Coriolis force, which is a fictitious inertial force. Its explanation as seen from an inertial system was given above: it is an effect of being in a rotating system, wherein points that are farther from the rotation axis have higher linear speeds. On the other hand, when viewed from the rotating system, we can describe the motion using Newton's second law, $\Sigma \vec{F} = m\vec{a}$, if we add a "pseudoforce" term corresponding to this Coriolis effect.

Let us determine the magnitude of the Coriolis acceleration for the simple case described above. (We assume v is large and distances are short, so we can ignore

FIGURE C-3 The origin of the Coriolis effect. Looking down on a rotating platform, (a) as seen from a nonrotating inertial system, and (b) as seen from the rotating platform as frame of reference.

A-18 APPENDIX C Rotating Frames of Reference; Inertial Forces; Coriolis Effect

gravity.) We do the calculation from the inertial reference frame (Fig. C-3a). The ball moves radially outward a distance $r_B - r_A$ at speed v in a time t given by

$$
r_{\rm B} \,-\,r_{\rm A}=\,v t.
$$

During this time, the ball moves to the side a distance s_A given by

 $s_{\rm A} \, = \, v_{\rm A} t.$

The man at B, in this time t , moves a distance

$$
s_{\mathrm{B}}\,=\,v_{\mathrm{B}}t.
$$

The ball therefore passes behind him a distance s (Fig. C-3a) given by

$$
s = s_B - s_A = (v_B - v_A)t.
$$

We saw earlier that $v_A = r_A \omega$ and $v_B = r_B \omega$, so

$$
s = (r_{\rm B} - r_{\rm A})\omega t.
$$

We substitute $r_{\rm B} - r_{\rm A} = vt$ (see above) and get

$$
s = \omega vt^2.
$$

This same s equals the sideways displacement as seen from the noninertial rotating system (Fig. $C-3b$).

We see immediately that Eq. $C-1$ corresponds to motion at constant acceleration. For as we saw in Chapter 2 (see Eq. 2–11b), $y = \frac{1}{2}at^2$ for a constant acceleration (with zero initial velocity in the y direction). Thus, if we write Eq. C–1 in the form $s = \frac{1}{2} a_{\text{Cor}} t^2$, we see that the Coriolis acceleration a_{Cor} is

$$
a_{\text{Cor}} = 2\omega v. \tag{C-2}
$$

This relation is valid for any velocity in the plane of rotation—that is, in the plane perpendicular to the axis of rotation (in Fig. $C-3$, the axis through point O perpendicular to the page).

Because the Earth rotates, the Coriolis effect has some interesting manifestations on the Earth. It affects the movement of air masses and thus has an influence on weather. In the absence of the Coriolis effect, air would rush directly into a region of low pressure, as shown in Fig. C-4a. But because of the Coriolis effect, the winds are deflected to the right in the Northern Hemisphere (Fig. C-4b), since the Earth rotates from west to east. So there tends to be a counterclockwise wind pattern around a low-pressure area. The reverse is true in the Southern Hemisphere. Thus cyclones rotate counterclockwise in the Northern Hemisphere and clockwise in the Southern Hemisphere. The same effect explains the easterly trade winds near the equator: any winds heading south toward the equator will be deflected toward the west (that is, as if coming from the east).

The Coriolis effect also acts on a falling body. A body released from the top of a high tower will not hit the ground directly below the release point, but will be deflected slightly to the east. Viewed from an inertial frame, this is because the top of the tower revolves with a slightly higher speed than does the bottom of the tower.

 $(C-1)$

 (c)

FIGURE C-4 (a) Winds (moving air masses) would flow directly toward a low-pressure area if the Earth did not rotate; (b) and (c): because of the Earth's rotation, the winds are deflected to the right in the Northern Hemisphere (as in Fig. $C-3$) as if a fictitious (Coriolis) force were acting.

APPENDIX

Molar Specific Heats for Gases, and the Equipartition of Energy

Molar Specific Heats for Gases

The values of the specific heats for gases depend on how the thermodynamic process is carried out. Two important processes are those in which either the volume or the pressure is kept constant, and Table D-1 shows how different they can be.

The difference in specific heats for gases is nicely explained in terms of the first law of thermodynamics and kinetic theory. For gases we usually use molar specific heats, C_V and C_P , which are defined as the heat required to raise 1 mol of a gas by 1° at constant volume and at constant pressure, respectively. In analogy to Eq. 14–2, the heat Q needed to raise the temperature of n moles of gas by ΔT is

Molar specific heats

It is clear from the definition of molar specific heat (compare Eqs. 14-2 and $D-1$) that

$$
C_V = Mc_V \quad \text{and} \quad C_P = Mc_P,
$$

where M is the molecular mass of the gas $(M = m/n \text{ in grams/mol})$. The values for molar specific heats are included in Table $D-1$. These values are nearly the same for different gases that have the same number of atoms per molecule.

Now we use kinetic theory of gases to see, first, why the specific heats of gases are higher for constant-pressure processes than for constant-volume processes.

Imagine that an ideal gas is slowly heated via these two processes—first at constant volume, and then at constant pressure. In both processes, we let the temperature increase by the same amount, ΔT . In the constant-volume process, no work is done since $\Delta V = 0$. Thus, according to the first law of thermodynamics, the heat added (denoted by Q_V) all goes into increasing the internal energy of the gas:

$$
Q_V = \Delta U.
$$

In the constant-pressure process, work is done. Hence the heat added, Q_p , must not only increase the internal energy but also is used to do work $W = P \Delta V$. Thus, for the same ΔT , more heat must be added in the process at constant pressure than at constant volume. For the process at constant pressure, the first law of thermodynamics gives

$$
Q_P = \Delta U + P \Delta V.
$$

Since ΔU is the same in the two processes (we chose ΔT to be the same), we can combine the two above equations:

$$
Q_P - Q_V = P \Delta V.
$$

From the ideal gas law, $V = nRT/P$, so for a process at constant pressure $\Delta V = nR \Delta T / P$. Putting this into the above equation and using Eqs. D-1, we find

$$
nC_P \Delta T - nC_V \Delta T = P\left(\frac{nR \Delta T}{P}\right)
$$

or, after cancellations.

$$
C_P - C_V = R. \tag{D-2}
$$

Since the gas constant $R = 8.315 \text{ J/mol} \cdot \text{K} = 1.99 \text{ cal/mol} \cdot \text{K}$, we predict that C_P will be larger than C_V by about 1.99 cal/mol·K. Indeed, this is very close to what is obtained experimentally, as the last column in Table $D-1$ shows.

Now we calculate the molar specific heat of a monatomic gas using the kinetic theory. For a process carried out at constant volume, no work is done, so the first law of thermodynamics tells us that

$$
\Delta U = Q_V.
$$

 $C_V = \frac{3}{2}$

For an ideal monatomic gas, the internal energy, U , is the total kinetic energy of all the molecules.

$$
U = N\left(\frac{1}{2}m\overline{v^2}\right) = \frac{3}{2}nRT
$$

as we saw in Section 14–2. Then, using Eq. D–1a, we write $\Delta U = Q_V$ as

$$
\Delta U = \frac{3}{2} nR \Delta T = nC_V \Delta T \tag{D-3}
$$

or

$$
R.
$$

Since $R = 8.315 \text{ J/mol} \cdot \text{K} = 1.99 \text{ cal/mol} \cdot \text{K}$, kinetic theory predicts that $C_V = 2.98 \text{ cal/mol} \cdot \text{K}$ for an ideal monatomic gas. This is very close to the experimental values for monatomic gases such as helium and neon (Table $D-1$). From Eq. D-2, C_P is predicted to be about 4.97 cal/mol·K, also in agreement with experiment (Table D-1).

Equipartition of Energy

The measured molar specific heats for more complex gases (Table $D-1$), such as diatomic (two-atom) and triatomic (three-atom) gases, increase with the increased number of atoms per molecule. We can explain this by assuming that the internal energy includes not only translational kinetic energy but other forms of energy as well. For example, in a diatomic gas (Fig. $D-1$), the two atoms can rotate about two different axes (but rotation about a third axis passing through the two atoms would give rise to neglible energy, since the moment of inertia is so small). The molecules can have rotational as well as translational kinetic energy.

FIGURE D-1 A diatomic molecule can rotate about two different axes.

APPENDIX D Molar Specific Heats for Gases, and the Equipartition of Energy A-21

 $(D-4)$

Degrees of freedom

Equipartition of energy

FIGURE D-2 A diatomic molecule can vibrate, as if the two atoms were connected by a spring. Of course they are not, but rather they exert forces on each other that are electrical in nature-of a form that resembles a spring force.

It is useful to introduce the idea of **degrees of freedom**, by which we mean the number of independent ways molecules can possess energy. For example, a monatomic gas has three degrees of freedom, because an atom can have velocity along the x, y, and z axes. These are considered to be three independent motions because a change in any one of the components would not affect the others. A diatomic molecule has the same three degrees of freedom associated with translational kinetic energy plus two more degrees of freedom associated with rotational kinetic energy (Fig. $D-1$), for a total of five degrees of freedom.

Table D-1 indicates that the C_V for diatomic gases is about $\frac{5}{3}$ times as great as for a monatomic gas—that is, in the same ratio as their degrees of freedom. This led nineteenth-century physicists to the principle of equipartition of energy. This principle states that energy is shared equally among the active degrees of freedom, and each active degree of freedom of a molecule has on the average an energy equal to $\frac{1}{2}kT$. Thus, the average energy for a molecule of a monatomic gas would be $\frac{3}{2}kT$ (which we already knew) and of a diatomic gas $\frac{5}{2}kT$. Hence the internal energy of a diatomic gas would be $U = N(\frac{5}{2}kT) = \frac{5}{2}nRT$, where n is the number of moles. Using the same argument we did for monatomic gases, we see that for diatomic gases the molar specific heat at constant volume would be $\frac{5}{2}R = 4.97 \text{ cal/mol} \cdot \text{K}$, in accordance with measured values. More complex molecules have even more degrees of freedom and thus greater molar specific heats.

However, measurements showed that for diatomic gases at very low temperatures, C_V has a value of only $\frac{3}{2}R$, as if there were only three degrees of freedom. And at very high temperatures, C_V was about $\frac{7}{2}R$, as if there were seven degrees of freedom. The explanation is that at low temperatures, nearly all molecules have only translational kinetic energy, so, no energy goes into rotational energy and only three degrees of freedom are "active." At very high temperatures, all five degrees of freedom are active plus two additional ones. We interpret the two new degrees of freedom as being associated with the two atoms vibrating, as if they were connected by a spring (Fig. $D-2$). One degree of freedom comes from the kinetic energy of the vibrational motion, and the second from the potential energy of vibrational motion $(\frac{1}{2}kx^2)$. At room temperature, these two degrees of freedom are apparently not active. Why fewer degrees of freedom are "active" at lower temperatures was eventually explained by Einstein using the quantum theory.

Solids

The principle of equipartition of energy can be applied to solids as well. The molar specific heat of any solid at high temperature is close to $3R$ (6.0 cal/mol·K), Fig. $D-3$. This is called the *Dulong and Petit value* after the scientists who first measured it in 1819. (Note that Table 14-1 gave the specific heats per kilogram, not per mole.) At high temperatures, each atom apparently has six degrees of freedom, although some are not active at low temperatures. Each atom in a crystalline solid can vibrate about its equilibrium position as if it were connected by springs to each of its neighbors (Fig. $D-4$). Thus it can have three degrees of freedom for kinetic energy and three more associated with potential energy of vibration in each of the x , y , and z directions, which is in accord with measured values.

FIGURE D-4 The atoms in a crystalline solid can vibrate about their equilibrium positions as if they were connected to their neighbors by springs. (The forces between atoms are actually electrical in nature.)

A-22 APPENDIX D Molar Specific Heats for Gases, and the Equipartition of Energy

 $\overline{}$ APPENDIX

Galilean and Lorentz Transformations

e now examine in detail the mathematics of relating quantities in one inertial reference frame to the equivalent quantities in another. In particular, we will see how positions and velocities *transform* (that is, change) as we go from one frame of reference to another.

We begin with the classical, or Galilean, viewpoint. Consider two reference frames S and S' which are each characterized by a set of coordinate axes, Fig. E-1. The axes x and y (z is not shown) refer to S, and x' and y' refer to S'. The x' and x axes overlap one another, and we assume that frame S' moves to the right (in the x direction) at speed v with respect to S. For simplicity let us assume the origins O and O' of the two reference frames are superimposed at time $t = 0$.

Now consider an event that occurs at some point P (Fig. E-1) represented by the coordinates x' , y' , z' in reference frame S' at the time t'. What will be the coordinates of P in S? Since S and S' overlap precisely initially, after a time t , S' will have moved a distance vt'. Therefore, at time t', $x = x' + vt'$. The v and z coordinates, on the other hand, are not altered by motion along the x axis; thus $y = y'$ and $z = z'$. Finally, since time is assumed to be absolute in Galilean–Newtonian physics, clocks in the two frames will agree with each other; so $t = t'$. We summarize these in the following Galilean transformation equations:

> $x = x' + vt'$ $y = y'$ **Galilean** $(E-1)$ $z = z'$ transformations $t = t'$.

These equations give the coordinates of an event in the S frame when those in the S' frame are known. If those in the S system are known, then the S' coordinates are obtained from

 $x' = x - vt$, $y' = y$, $z' = z$, $t' = t$.

These four equations are the "inverse" transformation and are very easily obtained from Eqs. E-1. Notice that the effect is merely to exchange primed and unprimed quantities and replace v by $-v$. This makes sense because from the S' frame, S moves to the left (negative x direction) with speed v .

FIGURE E-1 Inertial reference frame S' moves to the right at speed v with respect to inertial frame S.

Now suppose that the point P in Fig. $E-1$ represents an object that is moving. Let the components of its velocity vector in S' be u'_x , u'_y , and u'_z (we use u to distinguish it from the relative velocity of the two frames, v). Now $u'_x = \Delta x'/\Delta t'$, $u'_y = \Delta y'/\Delta t'$, and $u'_z = \Delta z'/\Delta t'$, where all quantities are as measured in the S' frame. For example, if at time t_1 ' the particle is at x_1 ' and a short time later, t'_2 , it is at x'_2 , then

$$
u'_x = \frac{x'_2 - x'_1}{t'_2 - t'_1} = \frac{\Delta x'}{\Delta t'}.
$$

Now the velocity of P as seen from S will have components u_x, u_y , and u_z . We can show how these are related to the velocity components in S' by using Eqs. $E-1$. For example,

$$
u_x = \frac{\Delta x}{\Delta t} = \frac{x_2 - x_1}{t_2 - t_1} = \frac{(x'_2 + vt'_2) - (x'_1 + vt'_1)}{t'_2 - t'_1}
$$

=
$$
\frac{(x'_2 - x'_1) + v(t'_2 - t'_1)}{t'_2 - t'_1}
$$

=
$$
\frac{\Delta x'}{\Delta t'} + v = u'_x + v.
$$

For the other components, $u'_y = u_y$ and $u'_z = u_z$, so we have

These are known as the Galilean velocity transformation equations. We see that the y and z components of velocity are unchanged, but the x components differ by v . This is just what we have used before when dealing with relative velocity. For example, if S' is a train and S the Earth, and the train moves with speed v with respect to Earth, a person walking toward the front of the train with speed u'_x will have a speed with respect to the Earth of $u_x = u'_x + v$.

Relativity theory

The Galilean transformations, Eqs. $E-1$ and $E-2$, are valid only when the velocities involved are not relativistic (Chapter 26)—that is, much less than the speed of light, c. We can see, for example, that the first of Eqs. $E-2$ will not work for the speed of light, c , which is the same in all inertial reference frames (a basic postulate in the theory of relativity). That is, light traveling in S' with speed $u'_x = c$ will have speed $c + v$ in S, according to Eq. E-2, whereas the theory of relativity insists it must be c in S. Clearly, then, a new set of transformation equations is needed to deal with relativistic velocities.

We will derive the required equations in a simple way, again looking at Fig. E-1. We assume the transformation is linear and of the form

$$
x = \gamma(x' + vt'), \qquad y = y', \qquad z = z'.
$$

That is, we modify the first of Eqs. E-1 by multiplying by a factor γ which is yet to be determined. But we assume the y and z equations are unchanged because we expect no length contraction in these directions. We won't assume a form for t , but will derive it. The inverse equations must have the same form with v replaced by $-v$. (The principle of relativity demands it, since S' moving to the right with respect to S is equivalent to S moving to the left with respect to S'.) Therefore

$$
x' = \gamma(x - vt).
$$

Now if a light pulse leaves the common origin of S and S' at time $t = t' = 0$, after a time t it will have traveled along the x axis a distance $x = ct$ (in S), or $x' = ct'$ (in S'). Therefore, from the equations for x and x' above,

$$
ct = \gamma(ct' + vt') = \gamma(c + v)t',
$$

$$
ct' = \gamma(ct - vt) = \gamma(c - v)t.
$$

We substitute t' from the second equation into the first and find $ct = \gamma(c + v)\gamma(c - v)(t/c) = \gamma^2(c^2 - v^2)\hat{i}/c$. We cancel out the t on each side and solve for γ to find

$$
\gamma = \frac{1}{\sqrt{1 - v^2/c^2}}.
$$

Now that we have found γ , we need only find the relation between t and t'. To do so, we combine $x' = \gamma(x - vt)$ with $x = \gamma(x' + vt')$:

$$
x' = \gamma(x - vt) = \gamma[\gamma(x' + vt') - vt].
$$

We solve for t and find $t = \gamma(t' + vx'/c^2)$. In summary,

$$
x = \frac{1}{\sqrt{1 - v^2/c^2}} (x' + vt'),
$$

\n
$$
y = y',
$$

\n
$$
z = z',
$$

\n
$$
t = \frac{1}{\sqrt{1 - v^2/c^2}} \left(t' + \frac{vx'}{c^2} \right).
$$
\n(E-3)

These are called the Lorentz transformation equations. They were first proposed, in a slightly different form, by Lorentz in 1904 to explain the null result of the Michelson-Morley experiment and to make Maxwell's equations take the same form in all inertial systems. A year later, Einstein derived them independently based on his theory of relativity. Notice that not only is the x equation modified as compared to the Galilean transformation but so is the t equation. Indeed, we see directly in this last equation, as well as in the first, how the space and time coordinates mix.

The relativistically correct velocity equations are readily obtained. For example, using Eqs. E-3 (we let $\gamma = 1/\sqrt{1 - v^2/c^2}$),

$$
u_x = \frac{\Delta x}{\Delta t} = \frac{\gamma(\Delta x' + v \Delta t')}{\gamma(\Delta t' + v \Delta x'/c^2)} = \frac{(\Delta x'/\Delta t') + v}{1 + (v/c^2)(\Delta x'/\Delta t')}
$$

$$
= \frac{u'_x + v}{1 + vu'_x/c^2}.
$$

The others are obtained in the same way, and we collect them here:

$$
u_x = \frac{u'_x + v}{1 + vu'_x/c^2},
$$
\n
$$
u_y = \frac{u'_y \sqrt{1 - v^2/c^2}}{1 + vu'_x/c^2},
$$
\n
$$
u_z = \frac{u'_z \sqrt{1 - v^2/c^2}}{1 + vu'_x/c^2}.
$$
\n(E-4) velocity transformations

The first of these equations is Eq. $26-9$, which we used in Section $26-11$ where we discussed how velocities do not add in our commonsense (Galilean) way, because of the denominator $(1 + vu_x'/c^2)$. We can now also see that the y and z components of velocity are also altered and that they depend on the x' component of velocity.

Lorentz

transformations

EXAMPLE E-1 Length contraction. Derive the length contraction formula, Eq. 26–2, from the Lorentz transformation equations.

SOLUTION Let an object of length L_0 be at rest on the x axis in S. The coordinates of its two end points are x_1 and x_2 , so that $x_2 - x_1 = L_0$. At any instant in S', the end points will be at x'_1 and x'_2 as given by the Lorentz transformation equations. The length measured in S' is $L = x'_2 - x'_1$. An observer in S' measures this length by measuring x'_2 and x'_1 at the same time (in the S' frame), so $t'_2 = t'_1$. Then, from the first of Eqs. E-3,

$$
L_0 = x_2 - x_1 = \frac{1}{\sqrt{1 - v^2/c^2}} (x_2' + vt_2' - x_1' - vt_1').
$$

Since $t'_2 = t'_1$, we have

$$
L_0 = \frac{1}{\sqrt{1 - v^2/c^2}} (x_2' - x_1') = \frac{L}{\sqrt{1 - v^2/c^2}},
$$

$$
L = L_0 \sqrt{1 - \frac{v^2}{c^2}},
$$

which is Eq. $26-2$.

or

EXAMPLE E-2 Time dilation. Derive the time dilation formula, Eq. 26-1, from the Lorentz transformation equations.

SOLUTION The time Δt_0 between two events that occur at the same place $(x'_2 = x'_1)$ in S' is measured to be $\Delta t_0 = t'_2 - t'_1$. Since $x'_2 = x'_1$, then from the last of Eqs. E-3, the time Δt between the events as measured in S is

$$
\Delta t = t_2 - t_1 = \frac{1}{\sqrt{1 - v^2/c^2}} \left(t_2' + \frac{vx_2'}{c^2} - t_1' - \frac{vx_1'}{c^2} \right)
$$

$$
= \frac{1}{\sqrt{1 - v^2/c^2}} (t_2' - t_1')
$$

$$
= \frac{\Delta t_0}{\sqrt{1 - v^2/c^2}},
$$

which is Eq. $26-1$. Notice that we chose S' to be the frame in which the two events occur at the same place, so that $x'_1 = x'_2$, and the terms containing x'_1 and x'_2 cancel out.

- 37. 5.50 eV.
- **39.** (a) 9.4×10^{-2} eV; (*b*) 6.3×10^{-10} m.
- 41. 6.47×10^{-4} eV.
- 43. (a) 146 V \leq $V_{\text{supply}} \leq 362$ V; (*b*) 3.34 k $\Omega \leq R_{\text{load}} < \infty$.

CHAPTER 30

- 1. 0.149 u.
- 3. 3726 MeV/ c^2 .
- 5. (b) 180 m; (c) 2.58×10^{-10} m.
- 7. 6×10^{26} , no, nucleon density is essentially the same for all nuclei.
- 9. 340 MeV.
- 11. 2.224 MeV.
- 13. 7.799 MeV.
- **15.** ${}^{23}_{11}$ Na: 8.11 MeV/ nucleon, $^{24}_{11}$ Na: 8.06 MeV/ nucelon.
- 17. (b) stable.
- 19. 0.783 MeV.
- **21.** (a) β^+ ;
	- (b) ${}^{22}_{11}Na \rightarrow {}^{22}_{10}Ne + e^+ + \nu$, 1.819 MeV.
- **23.** (a) $^{234}_{90}$ Th;
- (b) 234.04367 u.
- 25. 0.0855 MeV.
- **27.** (a) $^{32}_{16}S$;
- (b) 31.97152 u.
- 29. 0.862 MeV.
- 31. 0.9602 MeV, 0.9602 MeV, 0 MeV.
- 33. 5.31 MeV.
- 37. (a) 1.5×10^{-10} yr⁻¹; (b) 2.3 h. 39. $1/16$ (or 0.0625). 41. 1.31×10^{-20} nuclei. 43. (a) 3.13×10^{12} decays/s; (b) 3.12 \times 10¹² decays/s; (c) 4.26×10^5 decays/s. 45. 0.77 g. 47. 1.68×10^{-13} kg. 49. 2.6 min. 51. 2.58 \times 10⁻³ g. **53.** $T_{\frac{1}{2}}(^{218}_{84}\text{Po})$: $T_{\frac{1}{2}}(^{214}_{84}\text{Po}) = (1.2 \times 10^6)$: 1.
- 55. ${}^{232}_{90}Th \rightarrow {}^{228}_{88}Ra \rightarrow {}^{228}_{89}Ac \rightarrow$
- ${}^{228}_{90}Th \rightarrow {}^{224}_{88}Ra \rightarrow {}^{220}_{88}Rn$, ${}^{235}_{92}U \rightarrow {}^{231}_{90}Th \rightarrow {}^{231}_{91}Pa \rightarrow$
	- ${}^{227}_{89}\text{Ac} \rightarrow {}^{227}_{90}\text{Th} \rightarrow {}^{223}_{88}\text{Ra}.$
- 57. $N_{\rm D} = N_0(1 e^{-\lambda t}).$
- 59. 2.3×10^4 yr.
- 61. 41 yr.
- 63. 6.64 half-lives.
- 65. (b) 98%.
- 67. (a) $\frac{191}{77}$ Ir;
	- (b)

 $^{191}_{76}$ Os

 β ⁻ (0.14 MeV) 191 Ir* γ (0.042 MeV) $^{191}_{77}$ Ir* γ (0.129 MeV) 191 Ir

to the higher excited state.

- 69. 550 MeV, 2.5×10^{12} J.
- 71. (a) 2.4×10^5 yr;
	- (b) 2.5×10^5 yr, carbon dating is not useful for times on the order of 10⁵ yr or longer.
- 73. (a) KE_{α} : $KE_{\beta} = 5.48 \times 10^{-4}$: 1.
- 75. (a) 1.6%;
	- (b) 0.67%.
- 77. 0.18 decays/s or 11 decays/min.

CHAPTER 31

- **1.** $^{28}_{13}$ Al, β^- , $^{28}_{14}$ Si.
- 3. possible.
- 5. 5.701 MeV is released.
- 7. (a) yes;
	- (b) 19.85 MeV.
- 9. 4.730 MeV.
- 11. $n + \frac{14}{7}N \rightarrow \frac{14}{6}C + p$, 0.626 MeV.
- 13. (*a*) ${}_{2}^{3}$ He picks up a neutron;
	- (b) $^{11}_{6}C$;
	- (c) 1.856 MeV, exothermic.
- 15. 18.000953 u.
- 17. 173.3 MeV.

A-40 Answers to Odd-Numbered Problems

19. 1/1100. **21.** 3.7 \times 10⁻⁷ kg. 23. 630 kg. 25. 2.1×10^{-16} J or 1.3 keV. 29. $6.0 \times 10^{23} \,\text{MeV/g}$, $4.9 \times 10^{23} \,\text{MeV/g},$ 2.1×10^{24} MeV/g, 5.1×10^{23} MeV/g. 31. 0.38 g. 33. 5.3×10^3 kg/h. 35. (b) 26.73 MeV; (c) 1.94 MeV, 2.22 MeV, 7.55 MeV, 7.30 MeV, 2.75 MeV, 4.97 MeV; (d) greater repulsion from higher-Z nuclei. 37. 4.0 Gy. 39. 250 rads. 41. 200 counts/s. 43. 2.5 days. 45. 8.25 \times 10⁻⁷ Gy/day. 47. (a) $^{131}_{53}I \rightarrow ^{131}_{54}Xe + e^- + \bar{\nu}$; (b) 27 days; (c) 8×10^{-12} kg. 49. (a) $^{218}_{84}P_Q$; (b) radioactive, α decay: $^{218}_{84}Po \rightarrow ^{214}_{82}Pb + ^{4}_{2}He$, β decay: $^{218}_{84}Po \rightarrow ^{218}_{85}At + e^{-}$, 3.1 min for both; (c) chemically reacting; (d) 5.7×10^6 decays/s, 2.5×10^4 decays/s. 51. (a) $^{12}_{6}C$; (b) 5.701 MeV. 53. v_{235} : $v_{238} = 1.0043$: 1. 55. 5.1×10^{-2} rem/yr. 57. 4.7 m. 59. (a) 1300 kg; (b) 4.1×10^6 Ci. 61. (a) 4.0×10^{26} W; (*b*) 3.7 \times 10³⁸ protons/s; (c) 1.0×10^{11} yr. 63. (a) 3700 decays/s; (b) 5.2×10^{-4} Sv/yr, about 15% of background. 65. 7.274 MeV. 67. 96 yr. 69. 3 mCi.

CHAPTER 32

- 1. 7.29 GeV.
- 3. 1.8 T.
- 5. 13 MHz.

7. alpha particles: $\lambda_{\text{alpha}} = 2.2 \times$ nucleon size. $\lambda_{\text{proton}} = 4.4 \times \text{nucleon size.}$ 9. 1.8×10^{-19} m. 11. 5.5 T. 15. 33.9 MeV. 17. 1879.2 MeV. 19. 67.5 MeV. 21. 2.3×10^{-18} m. 23. (a) charge (and strangeness); (b) energy; (c) baryon number (and strangeness). 27. 69.3 MeV. 29. $KE_{A} = 8.6 \text{ MeV}, KE_{\pi} = 57.4 \text{ MeV}.$ 31. 52.3 MeV. 33. 7.5 \times 10⁻²¹ s. 35. (a) 1.3 keV; (b) 8.9 keV. 37. (a) forbidden, energy is not conserved; (b) forbidden, lepton number is not conserved: (c) possible. 39. (a) p; $(b) \overline{\Sigma}^-;$ (c) K⁻; $(d) \pi^{-}$; (e) D_{S}^- . 41. $D_{S}^{+} = c\overline{s}$. 43. W 45. (a) 0.38 A; (*b*) 1.0×10^2 m/s. 47. (a) 1.022 MeV; (b) 1876.6 MeV. 49. (a) forbidden by charge conservation: (b) possible by the strong interaction; (c) forbidden by strangeness conservation for the strong interaction, possible by the weak interaction; (d) forbidden by strangeness conservation for the strong interaction, possible by the weak interaction:

 (e) possible by weak interaction.

CHAPTER 33

3. 4.8 ly. 5. 0.059", 17 pc. 7. 110 yr. 9. 3.7 \times 10⁻². 11. 1.4×10^{-4} kg/m³. 13. 1.83×10^9 kg/m³, 3.33×10^5 times larger. 15. -0.092 MeV, 7.366 MeV. 17. $d_1/d_2 = 0.15$. 19. 4×10^{14} m. 21. 540°. **23.** 1.6 \times 10⁸ ly. 25. Double-slit experiment, 787-89 for electrons, 787-89 for light, 668-71 Down quark, 904 Drift speed, 509 Driving, around curve, 112-13 Dry cell, 495 Dry ice, 373 Duality, wave-particle, 765-68, 781 Dulong and Petit value, A-22 DVD player, 805, 806 Dye lasers, 805 Dynamic lift, 272-73 Dynamic rope, 105 pr Dynamics, 19, 72 ff rotational, 206 ff Dynamo (see Electric generator) Dyne (unit), 76 Dynodes, 856-57 $E = mc^2$, 744-47 Ear, human, 328-29 sensitivity of, 327, 328 Earthquakes, 304, 305, 306, 313 ECG. 487 Echolocation, 304 Eddy currents (eddies), 268, 594-95 Edison, Thomas, 485 Effective dose, 878 Effective values, 507 Efficiency, of heat engine, 160, 418 Carnot, 420 Einstein, Albert, 3, 353, 727-49, 758, 871, 914, 926 EKG, 487 Elastic collisions, 175-77 Elastic limit, 237 Elastic modulus, 238 and speed of sound, waves, 304 Elastic potential energy, 147, 289 Elastic region, 237 Elastic spring, 147 Elasticity, 237-41 Electric battery, 494-97, $520 - 21$ Electric cell, 494-95 Electric charge, 439 ff accelerating, gives rise to EM wave, 619 in atom, 441 calculating, 535 conservation of, 440-41, 523, 528-29, 848, 898 of electron, 445, 754-56 elementary, 445 induced, 442-43 motion of in magnetic field, $560 - 63$ point, 446, 450-51, 476-79 quantization of, 445 \overline{r} test." 450 Electric circuit ac, 506-8, 603-8

complete, 496, 497 containing capacitors, $533 - 35,603 - 8$ containing resistors, 498 ff, $520 - 45$ dc, 493 ff, 520-45 digital, 831 grounding, 539-41 household, 505 integrated, 830-31 and Kirchhoff's rules, 528 ff $LC, 608, 627$ $LR, 602-3$ LRC, 606-7 open, 496 RC, 535-37 rectifier, 829 resonant. 608 time constants of, 536, 602 Electric current, 493 and ff alternating (ac), 506-8, $603 - 8$ conduction (defn), 617 conventional (defn), 497 direct (dc) $(defn)$, 506 dicement, 617 hazards splaof, 538-41 induced, 584 leakage, 541 magnetic force on, 558-59 measuring, 541-45 microscopic view of, 509-10 and Ohm's law, 498-500 peak, 506-7 produced by changing magnetic field, 584 ff produces magnetic field, 557 rms, 507 Electric dipole, 455, 479-80, 818 Electric energy, 470-87 production of, 430 storage of, 484-85 Electric field, 450-54 and conductors, 456-57 Coulomb's law to determine, 458 in dielectric, 482-83 in Em wave, 617-19 energy stored in, 485 and equipotential lines, $474 - 75$ Gauss's law to determine, 458 lines of, 454-56 magnetic field produced by changing, 616 ff of point charge, 451 produced by changing magnetic field or flux, 591, 617 ff relation to electric potential, 474 Electric field lines, 454-56 Electric flux, 457-58, 617 Electric force, 439 ff Coulomb's law for, 444-47

Index $A-45$

Electric force (cont.) in molecular biology, 460-62, 479.818-21 Electric generator, 473, 520, 584, 592-93 Electric hazards, 538-41 Electric motor, 571-72 counter emf in, 593-94 Electric potential, 470-87 (see also Potential difference) of dipole, 479-80 relation to electric field, 474 of single point charge, $476 - 79$ Electric power, 502-5 in ac circuits, 606 in household circuits, 506-7 transmission, 595-97 Electric power generation, $430 - 31$ Electric shocks, 538-41 Electrical shielding, 457 Electricity, 439-545, 584 ff, $615 ff$ Gauss's law, 457-59 static, 440-41 Electrocardiogram (ECG, EKG), 487 Electrode, 494 Electrolyte, 494 Electromagnet, 567 Electromagnetic blood-flow measurement, 590 Electromagnetic (EM) waves, 615-28, 664 ff, 726-27, 729,730 Doppler effect for, 341 momentum transfer and radiation pressure, 625-26 Electromagnetic force, 128, 558-63, 586 ff, 616, 895-97 and ff Electromagnetic induction, 584 ff Electromagnetic oscillations, 608 Electromagnetic pumping, 576 pr Electromagnetic spectrum, $619 - 22$ Electromagnetism, 584-631 Electrometer, 443 Electromotive force (see Emf) Electron, 754-56, 766-68 charge on, 445, 754-56 discovery of, 754-56 in double slit experiment, 787-89 e/m of, 755 free, 442 lepton number of, 899 mass of, 756 in pair production, 764-65 as ‰ particle, 845-47 wave nature, 766-68, 780-81,789 "what is an," 768 Electron band theory, 825-26 Electron capture, 847

Electron cloud, 794, 796, 813 Electron configuration, 798-99 Electron degeneracy, 922 Electron microscopes, 754, $768 - 69$ Electron spin, 574, 795 Electron volt (unit), 476, 746, 838 Electronic devices, 485-86, 541-45, 626-28, 827-31 Electroscope, 442-43 Electrostatic unit (esu), 445 fn Electrostatics, 439-87 in photocopy machines and computer printers, 462-63 Electroweak theory, 128, 906-8 Elementary charge (defn), 445 Elementary particle physics, $889 - 910$ Elementary particles, 889-910 Elements ($defn$), 353 fn of lens, 711 periodic table of, 798-800 (see also inside back cover) production of, 922-23 transmutation of, 842, $863 - 66$ Elevator and counterweight, 88 Ellipse, 125 e/m for electron, 755 EM waves (see Electromagnetic (EM) waves) Emf. 520-22, (defn. 520) back, 593-94 counter, 593-94 of generator, 592-95 induced, 584 ff induced in moving conductor, 590-91 motional, 590 in series and in parallel, $532 - 34$ source of, 520-21 Emission spectrum, 771 Emission tomography, 881-82 Emissivity, 399-400 Emitter (transistor), 830-31 Emulsion detector, 857 Endoergic reaction (defn), 864 Endoscope, 646 Endothermic reaction, 864 Energy, 136, 141-60, 744-47 activation, 371, 816 binding, 775, 813, 816-17, 838-41 bond, 813, 817 conservation, 149-57, 389, 409, 529, 848, 898 degradation, 427 disintegration, 843 distinguished from heat and temperature, 386 electric (see Electric energy) in EM waves, 623-24 equipartition of, A-21-A-22 and first law of

thermodynamics, 408-10

molecular rotational and vibrational, 387, 822-23 nuclear, 431, 863-84 of photon, 762-63 potential, 144 ff, 470-71 quantization of, 756, 758, 795 reaction, 864 related to work, 141 ff relativistic, 744-47 rest, 744 rotational, 210-13, 822-23 in simple harmonic motion, 289-91 solar, 431 stored in electric field, $484 - 85$ stored in magnetic field, 602 thermal, 156, 386 threshold, 865, 888 pr total mechanical energy $(defn), 149$ transformation of, 155-56, $744 - 47$ unavailability of, 426-27 and uncertainty principle, 789-92 units of, 143 vibrational, 289-91, 823 of waves, 305-6 zero-point, 823 Energy bands, 825-26 Energy "buckets," 290 Energy conservation, law of, 149-57, 389, 409, 529, 848, 898 Energy density, 485, 602, 623 in electric field, 485 in EM wave, 623 in magnetic field, 602 Energy gap, 825 Energy levels: atomic, 775-76, 794 ff for fluorescence, 803 for lasers, 803-5 in molecules, 821-23 nuclear, 847 in solids, 825-26 Energy production and resources, 430-31 Energy states: in atoms, 775-76, 794-96 in molecules, 821-23 in nuclei, 847 Energy transfer, heat as, $385 - 86$ Engine, heat, 416-21, 430 Enriched uranium, 868 Entropy, 408, 424-25 in life processes, 427 second law of thermodynamics and, $424 - 25$

geothermal, 431

 $744 - 47$

ionization, 775, 778

mass and, 744-47

mechanical, 149-55

internal, 386-87, 408-15

kinetic, 141-44, 210-13,

statistics and, 428-29 Environmental pollution, 430 Enzymes, 817 Equally tempered chromatic scale, 329 Equation of continuity, 268-69 Equation of state, 361 for an ideal gas, 364 Equilibrium, 226-55, (defn, 227) conditions for, 227-29 stable, unstable, neutral, 236 thermal, 357 Equilibrium position (vibrational motion), 287 Equilibrium state (defn), 361 Equipartition of energy, $A - 21 - A - 22$ Equipotential lines, 474-75 Equipotential surfaces, 474-75 Equivalence principle, 926, 927 Erg (unit), 137, 143 Escherichia coli, 769 Estimated uncertainty, $5 fm, 6$ Estimating, 12-14 Esu (unit), 445 fn Ether, 730 Euclidean space, 928 Evaporation, 373-74, 395 Event, (defn, 731) Event horizon, 929 Everest, Mt., 121 Evolution: biological, 427 stellar, 918-24 Exchange particles (carriers of force), 896 Excited state: of atom, 775 of nucleon, 902 of nucleus, 847 Exclusion principle, 797-98, 813 Exoergic reaction, 864 Exothermic reaction, 864 Expansion, binomial, A-6-A-7 (see also inside back cover) Expansion joints, 354 Expansion of universe, 930-41 Expansion (rarefaction), 303, 324 Expansion, thermal, 354, $357 - 60$ Experimentation, 2 Exponential curves, 535, 602, 849 Exponential decay, 849 Exponential notation, A-3 Exponents and exponential notation, A-2-A-3 (see also inside back cover) Extensor muscles, 234 Extragalactic (defn), 917 Eye, 701-4, 711, 715-16 accommodation of, 702 far and near points of, 702 normal (defn), 702 resolution of, 715-16 structure and function of, $701 - 4$

Eyeglass lenses, 701-4 Eyepiece, 706, 707-9 f-stop, 698 Fahrenheit temperature scale, $355 - 56$ Falling bodies, 31-35 Fallout, radioactive, 871 Far point of eye, 702 Farad (unit), 481 Faraday, Michael, 450, 584 Faraday's law, 616 Farsighted eye, 702 Fermi, Enrico, 14, 766, 787, 797 fn, 846, 866, 868, 902 Fermilab, 893 Fermions, 797 fn, 906 Ferris wheel, 111 Ferromagnetism, 555, 573-75 Feynman diagram, 896 Feynman, Richard, 896 Fiber optics, 645-46 Fick's law of diffusion, 377 Fictitious (inertial) force, A-17 Field, 450, 895 (see also Electric field; Gravitational field; Magnetic field) Figure skating, spins in, 214 Film badge, 878 Film speed, 698 fn Filter (electrical), 605 Fine structure, 786, 795 First harmonic, 311 First law of thermodynamics, $408 - 15$ human metabolism and, $414 - 15$ in isobaric and isovolumetric processes, 413 First overtone, 332 Fission, 866-71 Fission bomb, 871 Fission fragments, 866 Flashlight bulb, 495 Flavor (of elementary particles), 906 Flexor muscles, 234 Floating objects, and density, 263, 266 Florence cathedral, 245 Flow of fluids, 268-74 laminar (defn), 268 streamline (defn), 268 in tubes, 275-76 turbulent, 268 Flow rate, 268-69, 275 Fluids, 255-85 (see also Gases) longitudinal wave speed in, 304 Fluorescence, 802-3 Fluorescent light bulbs, 803 Flux: electric, 617 magnetic, 586, 591 Flying buttress, 244 FM radio, 627 Focal length, 636, 641, 648, 650-51,656 Focal plane, 648

Focal point, 636, 641, 647 Focus, 636 Focusing, of camera, 698-99 Football, 58, 61, 66 pr, 67 pr Foot-pound (unit), 137, 143 Forbidden energy gap, 825 Forbidden transition, 797, 803 fn Force, 72-105, (defn, 73, 76), 128 (see also Electric force; Gravitational force) buoyant, 263-67 centrifugal, 110 centripetal, 109 color, 906-8 conservative, 148 ff contact, 81, 128, 450 Coriolis, A-18-A-19 Coulomb (defn), 447 (see also Electric force) dissipative, 156-58 elastic, 147, 237-41 electric, 439 ff electromagnetic, 128, 895 ff in equilibrium, 226-55 exerted by inanimate objects, 79 fictitious, A-17-A-18 of friction, 90-95, 112-14 of gravity, 80-83, 117-28, 897, 926-29 inertial, A-17 long-range, 841 in magnetic fields on charges and currents, 558-63 measurement of, 73 in muscles and joints, 234-35 net (defn), 76, 84 in Newton's laws, 75 ff nonconservative, 148 normal, 81 ff nuclear, 838-41, 855, 895 ff per unit mass, 456 pseudoforce, A-17 relation of momentum to, 168-69 relationship to acceleration, $75 - 77$ restoring, 287 short-range, 841 strong nuclear, 128, 840 ff, 895 ff, 897 types of in nature, 128, 897 units of, 76 van der Waals, 817-21 weak, 128, 841 ff, 846, 897 ff work done by, 137 ff Force diagram, 84 ff, 228 Force pump, 278 Forced convection, 397 Forced vibrations, 299 Formulas, mathematical (see inside back cover) Forward biased diode, 828 Fossil-fuel power plants, 430, 431, 592 Foucault, Jean, 666-67 Four-dimensional space-time, 742, 928

Fourier analysis, 334 Four-stroke-cycle engine, 417 Fovea, 701 Fractions (see inside back cover) Fracture, 237, 241-43 Frame of reference (see Reference frames) Franklin, Benjamin, 440 Franklin, Rosalind, 718 Free fall, 124 Free space, permittivity of, 445 Free-body diagram, 84 ff, 228 Freedom, degrees of, A-22 Freezing point (defn), 355 fn, 373 table of, 392 Frequency, 108, 200, 288, $292 - 93$ of audible sound, 323 beat, 337 carrier, 626 of circular motion, 108 cyclotron, 892 fundamental, 310, 311, $330 - 34$ infrasonic, 324 of light, 620 natural, 299, 310 resonant, 299, 310, 329, 608 of rotation, 200 ultrasonic, 343 of vibration, 286 of wave, 302, 305, 306-7 Frequency modulation (FM), 627 Fresnel, Augustin, 673 Friction, 73-74, 90-95, 112-14 coefficients of, 90, 91 kinetic, 90 ff in rolling, 90, 211-12 static, 90, 91-92, 211-12 Fringes, interference (defn), 668 Frisch, Otto, 866 Full-wave rectifier, 829 Fundamental constants (see inside front cover) Fundamental frequency, 310, 311, 330-34 Fuse, 505-6 Fusion bomb, 874 Fusion, heat of, 392 Fusion, nuclear, 871-75 in stars, 872, 873, 921, 938 Fusion reactor, 874-75 Galaxies, 915-18, 940 clusters, 917-18 mass of, 916 Galilean telescope, 708 Galilean transformation. $A-23-A-26$ Galilean velocity transformations, A-2, $A - 24 - A - 25$ Galilean-Newtonian relativity, 727-30, A-23-A-24

Galileo, 2, 19, 31-32, 54-55, 73-74, 297, 354, 622, 633, 706 fn, 708, 727, 728, 742, 915 Galvani, Luigi, 4, 494 Galvanometer, 541-44, 571 Gamma camera, 881 Gamma decay, 842, 847-48 Gamma rays, 620, 842, 847-48 Gamow, George, 726, 934 Gas constant, 364 Gas lasers, 805 Gas laws, 361-67 Gas tank overflow, 359 Gases, 255, 353-54, 361-73, $410 - 14$ change of phase, 371-73, $391 - 92$ definition, 255, 353, 372 ideal, 363-67 light emitted by, 771-73 molar specific heats for, $A-20-A-21$ real, 371-73 work done by, 410-14 Gauge bosons, 901, 905, 907 Gauge pressure, 259 Gauge theory, 907 Gauges, pressure, 260-62 Gauss, Karl Friedrich, 457 Gauss' Law, 457-59, 616 Gauss (unit), 559 Gav-Lussac, Joseph, 363 Gay-Lussac's law, 363 Geiger counter, 856-57 Gell-Mann, M., 904 General theory of relativity, 914, 926-29 Generator, electric, 430, 473. 520, 584, 592-93 Genetic code, 820 Genetic damage, 876, 878 Geodesic. 928 Geological time scale dating, $854 - 55$ Geometric optics, 632-56, $(defn, 632)$ Geometry, plane, A-7-A-8 (see also inside back cover) Geometry (review), A-7-A-8 Geophysical applications, 122 Geosynchronous satellite, 123 Geothermal energy, 431 Germanium, 826, 827 Germer, L. H., 767 GeV (see Electron volt (unit)) Glaser, D. A., 857 Glashow, S., 907 Glasses, eye, 701-4 Global positioning system (GPS), 17 pr, 134 pr, 739 Global warming, 430 Glueballs, 906 fn Gluino, 910 Gluons, 890, 897, 906-7 Gophers, air supply, 274 GPS, 17 pr, 134 pr, 739 Gradient: concentration, 377 temperature, 396 velocity, 274

Gram (unit), 9,76 Grand unified era, 937 Grand unified theory, 128. $908 - 9$ Graphical analysis: of linear motion, 36-37 for work, 141 Grating, diffraction, 676-78 Gravitation, universal law of, 117-20, 445, 926 Gravitational collapse, 929 Gravitational constant, 119 Gravitational field, 456, 926-29 Gravitational force, 80-83. 117-28, 897, 926-29 Gravitational mass, 926-27 Gravitational potential energy, $144 - 45$ Gravitational slingshot effect, 193 pr Graviton, 897, 910 Gravity, 32-34, 80-83, 117-28, $926 - 29$ acceleration of, 32-34, 118, 121 center of, 183-84, 229 and curvature of space, $926 - 29$ effect on light, 927, 929 on Moon, 109 specific, 256 Gravity anomalies, 122 Gravity waves, 942 Gray (unit), 877 Greek alphabet (see inside front cover) Grid (electrode), 486 Grimaldi, Francesco, 666, 670 Ground fault, 599 Ground fault circuit interrupter (GFCI), 599 Ground state of atom (defn), 775 Grounds and grounding, electrical, 497, 539-41 Groves, Leslie, 871 Guanine, 460-61, 818 Gun recoil, 172 GUT, 908-10 h-bar (h) , 791 Hadron, 901-2, 937 Hadron era, 937 Hahn, Otto, 866 Hair dryer, 508 Half-life, 848 ff Half-wave rectification, 829 Halley's comet, 133 pr Halogens, 799 Hammer: action-reaction pair in striking, 78 work done by, 143 Hard drive and bit speed, 200 Harmonic motion: damped, 298

 $332 - 33$ Hazards of electricity, 538-41 Head, magnetic, 598 Hearing in humans, 325, 328-29 threshold of, 329 Heart, defibrillator for, 485, 538 fn Heart, human, 278-79 and blood flow, 269, 275-76 ECG, 487 pacemakers, 538 as pump, 278-79 Heartbeats, number of, 13 Heat, 384-407, (defn, 385) compared to work, 408 conduction, convection, radiation, 395-402 distinguished from internal energy and temperature, 386 in first law of thermodynamics, 408 ff as flow of energy, 385-86 and human metabolism, $414 - 15$ latent, 391-95 loss through windows, 396 lost by body, 399, 400 mechanical equivalent of, 385 specific, 387-88 Heat capacity, 405 pr (see also Specific heat) Heat death, 426-27 Heat engines, 416-21, 430 efficiency of, 418 temperature difference and, 417 and thermal pollution, 430 Heat of fusion, 392 Heat of vaporization, 392 Heat pump, 423 Heat reservoir (defn), 410 Heat transfer, 395-402 Heating, convection, house, 398 Heating duct, 269 Heavy elements, 922-23 Heavy water, 868 Heisenberg uncertainty principle, 789-92 Heisenberg, Werner, 787, 790 Helium nuclei, 770, 838-39, 842-44, 872-74, 938 Helium-neon laser, 805 Henry, Joseph, 584, 600 Henry (unit), 600 Hertz, Heinrich, 619-20 Hertz (unit), 200, 288 Hertzsprung-Russell diagram, 920 ff Higgs boson, 908 Higgs field, 908 High jump, 185 High-energy physics, 889-910 High-temperature superconductors, 510 Highway buckling, 361

Harmonics, 310, 311, 330 fn,

Highway mirages, 667 Hiking trail, convection, 398-99 Holes (in semiconductor), 826, 827 Hologram and holography, $806 - 7$ Hooke, Robert, 237, 680 fn Hooke's law, 147, 237, 287 ff Horsepower (unit), 158 Hot wires, 540 H-R diagram, 920 ff Hubble age, 933 Hubble, Edwin, 917, 930 Hubble space telescope, 134 pr, 713, 923 Hubble's constant, 931 Hubble's law, 931 and ff Human body: balance and, 236 center of mass for, 184-85 energy, metabolism of, $414 - 15$ radiative heat loss of, 400 temperature, 356, 395 Human ear, 325, 328-29 Humidity, 375-76 partial pressure and, $375 - 76$ relative, 375-76 Huygens, Christiaan, 665 Huygens' principle, 665-66 Hydraulic brakes, 260 Hydraulic lift, 260 Hydrodynamics, 268 ff Hydroelectric power, 431 Hydrogen atom: Bohr theory of, 773-79 ground state and excited state of, 775 mass of, 367 quantum mechanics, 794-97 spectrum of, 771-73 Hydrogen bomb, 874 Hydrogen bond, 818-20 Hydrogen molecule, 813-16, 823 Hydrometer, 266-67 Hyperopia, 702 Hysteresis, 573-75 Hysteresis loop, 575 Ice, 360-61, 373, 393, 422 Ice skating, action-reaction pair in. 78 Ideal gas, 368 internal energy of, 368, $386 - 87$ Ideal gas law, 363-67 Identities, trigonometric, A-7 (see also inside back cover) Image distance, 634, 638 Image formation, 637 Images, 634 ff CAT scan, 718-21

fiber optic, 645-46

formed by lens, 647-50 formed by plane mirror, $633 - 35$ formed by spherical mirror, $635 - 42$ MRI, 882-84 NMR, 882-84 PET and SPET, 881-82 picture sharpness, 700 real (defn), 634, 637, 649 tomographic, 719 virtual (defn), 634, 640, 650 X-ray, 718-19 Imaging: CAT, 718-21 medical, 343-45, 718-21, 880-84 MRI, 882-84 PET, SPET, 881-82 thermography, 402 ultrasound, 343-45 Impedance, 606-7 Impulse, 173-75 Incidence, angle of, 308, 312, 633, 643 Incident wave, 308 Inclines, motion on, 94-95. $211 - 12$ Incoherent sources of light, 671 Indeterminancy principle (see Uncertainty principle) Index of refraction, 642, 672 Induced charge, 584-85 Induced electric charge, 442-43 Induced emf, 584 ff in generator, 592-95 in transformer, 595-97 Inductance, 600-601 in ac circuits, 603-4 mutual, 600 self, 600-601 solenoid, 601 Induction: electromagnetic, 584 ff Faraday's law of, 586 ff pulse, 595 Induction stove, 588 Inductive reactance, 604 Inductor, 600 ff Inelastic collisions, 175-76, 178-79 Inertia, 74 law of, 74 moment of, 206 and ff, (defn, 207) rotational, 206-8 Inertial confinement, 875 Inertial forces, A-17 Inertial mass, 926-27 Inertial reference frame, 74, 727, A-16-A-17 Infarct, 487 Inflationary scenario, 937, 942 Infrared radiation, 399, 620, 671 Infrasonic waves, 324 Insect, on water, 276-77 Insertions (muscle attachment points), 234

forced, 299

simple, 287-97

Instantaneous angular acceleration, 197 Instantaneous angular velocity, 196 Instruments electrical, 541-45 musical, 329-35 Insulation, thermal, 396-97 Insulators: electrical, 441-42, 825 thermal, 396 Integrated circuits, 830-31 Intensity: of EM waves, 624 of general waves, 305, 306-7 of light, 671 of sound, 325-27 Intensity level, 325, 328-29 Interference, 308-9, 335-36, 668 ff constructive, 308-9, 335-36, 668 destructive, 308-9, 310, 335-36, 668 of electrons, 788-89 of light waves, 668 ff of sound waves, 335-37 thin film, 679-83 in time, 336-37 of water waves, 309 of waves on a string, 308 Interference fringes, 668 ff Interference microscope, 716 Interferometer, 684 Internal combustion engine, $416 - 17$ Internal conversion, 847-48 Internal energy, 386-87, $408 - 15$ Internal reflection, 645-46 Internal resistance, 521 Interneuron, 511 Intervertebral disc, 235 Intrinsic semiconductor, 826, 827 Inverse proportion, A-1 Inverted population, 803 Ion $(defn), 441$ in axons, 511 Ionic bonds, 814, 815, 817, 824 Ionization energy, 775, 778 Ionizing radiation (defn), 876 IR radiation, 399, 620, 671 **Iris**, 701 Irreversible process (defn), 419 Isobaric process, 411 Isochoric (isovolumetric) process, 411 Isomer, 847-48 Isotherm, 410 Isothermal process, 410, 412 Isotopes, 573, 836, A-12-A-15 mean life of, 850 in medicine, 880-81 Iterative technique, 720 Jeweler's loupe, 705 Joints:

expansion, 354 human, forces in, 234-35 Joule, James Prescott, 385 Joule (unit), 137, 143, 204 fn, 385 Jumping, impulse on landing after, 174-75 Junction diode, 828-29 Junction rule (see Kirchhoff's rules) Junction transistor, 830 Jupiter, 133 K lines, 800 K 2, cover, 10, 11 Kant, Immanuel, 917 Kaon, 901 K-capture, 847 Kelvin temperature scale, 355, $362 - 63$ Kelvin (unit), 362 Kelvin-Planck statement of second law of thermodynamics, 421 Kepler, Johannes, 125 Keplerian telescopes, 706 Kepler's laws, 125-28 Kicked football, 58, 61, 66 pr, 67_{pr} Kilocalorie (unit), 385 Kilogram (unit), 9,75 Kilowatt-hour (unit), 164, 504 Kinematic equations, 27, 56, 201 Kinematics: for rotational motion, 201-3 translational motion, 19-71 for uniform circular motion, $106 - 9$ Kinetic energy, 141-44, 210-13, $744 - 47$ in collisions, 175-79 definition, 142 molecular, 370 relativistic, 744-47 rotational, 210-13 translational, 142 ff Kinetic friction, 90 ff Kinetic theory, 352, 367-71, 395 postulates of, 368 Kirchhoff, G. R, 528 Kirchhoff's rules, 528-31 Lake, volume of, 12-13 Laminar flow (defn), 268 Laminated armatures, 594 Laminated iron cores, 595 Land, Edwin, 685 Landing, impulse on, 174-75 Lanthanides, 800

Zweig, G., 904

CHAPTER 1: Introduction, Measurement, Estimating

Answers to Questions

- 1. (*a*) Fundamental standards should be accessible, invariable, indestructible, and reproducible. A particular person's foot would not be very accessible, since the person could not be at more than one place at a time. The standard would be somewhat invariable if the person were an adult, but even then, due to swelling or injury, the length of the standard foot could change. The standard would not be indestructible – the foot would not last forever. The standard could be reproducible – tracings or plaster casts could be made as secondary standards.
	- (*b*) If any person's foot were to be used as a standard, "standard" would vary significantly depending on the person whose foot happened to be used most recently for a measurement. The standard would be very accessible, because wherever a measurement was needed, it would be very easy to find someone with feet. The standard would be extremely variable – perhaps by a factor of 2. That also renders the standard as not reproducible, because there could be many reproductions that were quite different from each other. The standard would be almost indestructible in that there is essentially a limitless supply of feet to be used.
- 2. There are various ways to alter the signs. The number of meters could be expressed in one significant figure, as "900 m (3000 ft)". Or, the number of feet could be expressed with the same precision as the number of meters, as "914 m (2999 ft)". The signs could also be moved to different locations, where the number of meters was more exact. For example, if a sign was placed where the elevation was really 1000 m to the nearest meter, then the sign could read "1000 m (3280 ft)".
- 3. Including more digits in an answer does not necessarily increase its accuracy. The accuracy of an answer is determined by the accuracy of the physical measurement on which the answer is based. If you draw a circle, measure its diameter to be 168 mm and its circumference to be 527 mm, their quotient, representing π , is 3.136904762. The last seven digits are meaningless – they imply a greater accuracy than is possible with the measurements.
- 4. The problem is that the precision of the two measurements are quite different. It would be more appropriate to give the metric distance as 11 km, so that the numbers are given to about the same precision (nearest mile or nearest km).
- 5. A measurement must be measured against a scale, and the units provide that scale. Units must be specified or the answer is meaningless – the answer could mean a variety of quantities, and could be interpreted in a variety of ways. Some units are understood, such as when you ask someone how old they are. You assume their answer is in years. But if you ask someone how long it will be until they are done with their task, and they answer "five", does that mean five minutes or five hours or five days? If you are in an international airport, and you ask the price of some object, what does the answer "ten" mean? Ten dollars, or ten pounds, or ten marks, or ten euros?
- 6. If the jar is rectangular, for example, you could count the number of marbles along each dimension, and then multiply those three numbers together for an estimate of the total number of marbles. If the jar is cylindrical, you could count the marbles in one cross section, and then multiply by the number of layers of marbles. Another approach would be to estimate the volume of one marble. If we assume that the marbles are stacked such that their centers are all on vertical and horizontal lines, then each marble would require a cube of edge 2R, or a volume of $8R³$, where R is the radius of a marble. The number of marbles would then be the volume of the container divided by $8R³$.
- 7. The result should be written as 8.32 cm. The factor of 2 used to convert radius to diameter is exact it has no uncertainty, and so does not change the number of significant figures.
- 8. $\sin 30.0^{\circ} = 0.500$ $\sin 30.0^{\circ} = 0.500$
- 9. Since the size of large eggs can vary by 10%, the random large egg used in a recipe has a size with an uncertainty of about $\pm 5\%$. Thus the amount of the other ingredients can also vary by about $\pm 5\%$ and not adversely affect the recipe.
- 10. In estimating the number of car mechanics, the assumptions and estimates needed are: the population of the city the number of cars per person in the city the number of cars that a mechanic can repair in a day
	- the number of days that a mechanic works in a year
	- the number of times that a car is taken to a mechanic, per year

We estimate that there is 1 car for every 2 people, that a mechanic can repair 3 cars per day, that a mechanic works 250 days a year, and that a car needs to be repaired twice per year.

(*a*) For San Francisco, we estimate the population at one million people. The number of mechanics is found by the following calculation.

$$
(1 \times 10^{6} \text{ people}) \left(\frac{1 \text{ car}}{2 \text{ people}}\right) \left(\frac{2 \frac{\text{repairs}}{\text{year}}}{1 \text{ car}}\right) \left(\frac{1 \text{ yr}}{250 \text{ workdays}}\right) \left(\frac{1 \text{ mechanic}}{3 \frac{\text{repairs}}{\text{workday}}}\right) = \boxed{1300 \text{ mechanics}}
$$

(*b*) For Upland, Indiana, the population is about 4000. The number of mechanics is found by a similar calculation, and would be $\overline{5}$ mechanics. There are actually two repair shops in Upland, employing a total of 6 mechanics.

Solutions to Problems

[1] (a) 14 billion years =
$$
1.4 \times 10^{10}
$$
 years
\n(b) $(1.4 \times 10^{10} \text{ y})(3.156 \times 10^{7} \text{s/1 y}) = 4.4 \times 10^{17} \text{s}$

2. (*a*) 214 3 significant figures (*b*) 81.60 4 significant figures (*c*) 7.03 3 significant figures (*d*) 0.03 1 significant figure (*e*) 0.0086 2 significant figures (*f*) 3236 4 significant figures (*g*) 8700 2 significant figures

- 3. (*a*) $1.156 = 1.156 \times 10^0$ $1.156 = 1.156 \times 10^{9}$
	- (*b*) $21.8 = 2.18 \times 10^1$ $21.8 = 2.18 \times 10^{1}$
	- (c) $0.0068 = 6.8 \times 10^{-3}$ $0.0068 = 6.8 \times 10^{-3}$
	- (*d*) $27.635 = 2.7635 \times 10^{1}$ $27.635 = [2.7635 \times 10^1]$
	- (e) 0.219 = 2.19×10^{-1} $0.219 = 2.19 \times 10^{-1}$
	- (*f*) $444 = 4.44 \times 10^2$ $444 = 4.44 \times 10^2$
- 4. (*a*) $8.69 \times 10^4 = 86,900$ $8.69 \times 10^4 = 86,900$ (*b*) $9.1 \times 10^3 = |9,100|$ $9.1 \times 10^3 = |9,100|$
	- (c) $8.8 \times 10^{-1} = 0.88$ $8.8 \times 10^{-1} = 0.88$
	- (d) $4.76 \times 10^2 = 476$ $4.76 \times 10^{2} = 476$
	- (*e*) $3.62 \times 10^{-5} = 0.0000362$ $3.62 \times 10^{-5} = 0.0000362$
- 5. The uncertainty is taken to be 0.01 m. 0.01 m 1000 m % uncertainty = $\frac{0.01 \text{ m}}{100\%}$ = $\frac{1\%}{100\%}$ 1.57 m

6. % uncertainty =
$$
\frac{0.25 \text{ m}}{3.76 \text{ m}} \times 100\%
$$
 = 6.6%

7. (a) % uncertainty =
$$
\frac{0.2 \text{ s}}{5 \text{ s}} \times 100\% = \boxed{4\%}
$$

\n(b) % uncertainty = $\frac{0.2 \text{ s}}{50 \text{ s}} \times 100\% = \boxed{0.4\%}$
\n(c) % uncertainty = $\frac{0.2 \text{ s}}{300 \text{ s}} \times 100\% = \boxed{0.07\%}$

8. To add values with significant figures, adjust all values to be added so that their exponents are all the same.

$$
9.2 \times 10^3 s + 8.3 \times 10^4 s + 0.008 \times 10^6 s = 9.2 \times 10^3 s + 83 \times 10^3 s + 8 \times 10^3 s = (9.2 + 83 + 8) \times 10^3 s
$$

= $100 \times 10^3 s =$ $\boxed{1.00 \times 10^5 s}$

When adding, keep the least accurate value, and so keep to the "ones" place in the parentheses.

- 9. $(2.079 \times 10^2 \text{ m})(0.082 \times 10^{-1}) = 1.7 \text{ m}$. When multiplying, the result should have as many digits as the number with the least number of significant digits used in the calculation.
- 10. To find the approximate uncertainty in the area, calculate the area for the specified radius, the minimum radius, and the maximum radius. Subtract the extreme areas. The uncertainty in the area is then half this variation in area. The uncertainty in the radius is assumed to be 0.1×10^4 cm. 0.1×10^4 cm.

$$
A_{\text{specified}} = \pi r_{\text{specified}}^2 = \pi \left(3.8 \times 10^4 \text{ cm}\right)^2 = 4.5 \times 10^9 \text{ cm}^2
$$

\n
$$
A_{\text{min}} = \pi r_{\text{min}}^2 = \pi \left(3.7 \times 10^4 \text{ cm}\right)^2 = 4.30 \times 10^9 \text{ cm}^2
$$

\n
$$
A_{\text{max}} = \pi r_{\text{max}}^2 = \pi \left(3.9 \times 10^4 \text{ cm}\right)^2 = 4.78 \times 10^9 \text{ cm}^2
$$

\n
$$
\Delta A = \frac{1}{2} \left(A_{\text{max}} - A_{\text{min}}\right) = \frac{1}{2} \left(4.78 \times 10^9 \text{ cm}^2 - 4.30 \times 10^9 \text{ cm}^2\right) = 0.24 \times 10^9 \text{ cm}^2
$$

\nThus the area should be quoted as $A = \left(4.5 \pm 0.2\right) \times 10^9 \text{ cm}^2$

11. To find the approximate uncertainty in the volume, calculate the volume for the specified radius, the minimum radius, and the maximum radius. Subtract the extreme volumes. The uncertainty in the volume is then half this variation in volume.

$$
V_{\text{specified}} = \frac{4}{3}\pi r_{\text{specified}}^3 = \frac{4}{3}\pi \left(2.86 \text{ m}\right)^3 = 9.80 \times 10^1 \text{ m}^3
$$
\n
$$
V_{\text{min}} = \frac{4}{3}\pi r_{\text{min}}^3 = \frac{4}{3}\pi \left(2.77 \text{ m}\right)^3 = 8.903 \times 10^1 \text{ m}^3
$$
\n
$$
V_{\text{max}} = \frac{4}{3}\pi r_{\text{max}}^3 = \frac{4}{3}\pi \left(2.95 \text{ m}\right)^3 = 10.754 \times 10^1 \text{ m}^3
$$
\n
$$
\Delta V = \frac{1}{2}\left(V_{\text{max}} - V_{\text{min}}\right) = \frac{1}{2}\left(10.754 \times 10^1 \text{ m}^3 - 8.903 \times 10^1 \text{ m}^3\right) = 0.926 \times 10^1 \text{ m}^3
$$
\nThe percent uncertainty is $\frac{\Delta V}{V_{\text{specified}}} = \frac{0.923 \times 10^1 \text{ m}^3}{9.80 \times 10^1 \text{ m}^3} \times 100 = 0.09444 = 9\%$

- 12. (*a*) 286.6 mm 286.6×10^{-3} m $0.286.6$ m 286.6×10^{-3} m 0.286 6 m (*b*) $85 \,\mu\text{V}$ $85 \times 10^{-6}\,\text{V}$ $0.000085\,\text{V}$ $\frac{6}{10}$ 0.000.095 V 85×10^{-6} V $[0.000 085 V]$ (*c*) 760 mg 760×10^{-6} kg $\left[0.000\right]760$ kg (if last zero is significant) 760×10^{-6} kg $\qquad \qquad \text{[0.000 760 kg]}$ (if last zero is significant) (*d*) 60.0 ps 60.0 $\times 10^{-12}$ s 0.000 000 000 0600 s (*e*) 22.5 fm 22.5 \times 10⁻¹⁵ m $\left[0.000\ 000\ 000\ 000\ 022\ 5\ \text{m}\right]$ (*f*) 2.50 gigavolts 2.5×10^9 volts $\Big| 2,500,000,000$ volts 2.5×10^{9} volts $\left| 2,500,000,000 \right|$ volts
- 13. (*a*) 1×10^6 volts $1 \text{ megavolt} = 1$ Mvolt 1×10^6 volts $1 \text{ megavolt} = 1$ Mvolt (*b*) 2×10^{-6} meters $\boxed{2 \text{ micrometers}} = 2 \mu \text{m}$ 2×10^{-6} meters $2 \text{ micrometers} = 2 \mu \text{m}$ (*c*) 6×10^3 days $\begin{bmatrix} 6 \text{ kilodays} \end{bmatrix} = 6 \text{ kdays}$ 6×10^3 days $\begin{bmatrix} 6 \text{ kilodays} \end{bmatrix} = 6 \text{ kdays}$ (*d*) 18×10^2 bucks $\boxed{18 \text{ hectobucks}} = 18 \text{ hbulks}$ 18×10^2 bucks 18 hectobucks = 18 hbucks (*e*) 8×10^{-9} pieces $\left|8 \right| = 8$ npieces 8×10^{-9} pieces 8 nanopieces $= 8$ npieces
- 14. (*a*) Assuming a height of 5 feet 10 inches, then $5'10'' = (70 \text{ in })(1 \text{ m}/39.37 \text{ in}) = |1.8 \text{ m}|$
	- (*b*) Assuming a weight of 165 lbs, then $(165 \text{ lbs}) (0.456 \text{ kg}/1 \text{ lb}) = |75.2 \text{ kg}|$

Technically, pounds and mass measure two separate properties. To make this conversion, we have to assume that we are at a location where the acceleration due to gravity is 9.8 m/s².

15. *(a)* 93 million miles = $(93 \times 10^6 \text{ miles}) (1610 \text{ m/1 mile}) = 1.5 \times 10^{11} \text{ m}$ (*b*) 1.5×10^{11} m = 150×10^{9} m = $|150$ gigameters or 1.5×10^{11} m = 0.15×10^{12} m = $|0.15$ terameters

16. (a)
$$
1 \text{ ft}^2 = (1 \text{ ft}^2)(1 \text{ yd}/3 \text{ ft})^2 = 0.111 \text{ yd}^2
$$

\n(b) $1 \text{ m}^2 = (1 \text{ m}^2)(3.28 \text{ ft}/1 \text{ m})^2 = 10.8 \text{ ft}^2$

17. Use the speed of the airplane to convert the travel distance into a time.

$$
1.00 \text{ km} \left(\frac{1 \text{ h}}{950 \text{ km}} \right) \left(\frac{3600 \text{ s}}{1 \text{ h}} \right) = 3.8 \text{ s}
$$

18. (a)
$$
1.0 \times 10^{-10}
$$
 m = $(1.0 \times 10^{-10}$ m) $(39.37$ in/1 m) = $\frac{3.9 \times 10^{-9}$ in
\n(b) $(1.0 \text{ cm}) \left(\frac{1 \text{ m}}{100 \text{ cm}}\right) \left(\frac{1 \text{ atom}}{1.0 \times 10^{-10} \text{ m}}\right) = \boxed{1.0 \times 10^8 \text{ atoms}}$

19. To add values with significant figures, adjust all values to be added so that their units are all the same.

1.80 m + 142.5 cm + 5.34 × 10⁵ μ m = 1.80 m + 1.425 m + 0.534 m = 3.759 m = $\boxed{3.76 \text{ m}}$ When adding, the final result is to be no more accurate than the least accurate number used. In this case, that is the first measurement, which is accurate to the hundredths place.

20. (a)
$$
(1k/h)\left(\frac{0.621 \text{ mi}}{1 \text{ km}}\right) = \frac{0.621 \text{ mi/h}}{1 \text{ m}}
$$

\n(b) $(1m/s)\left(\frac{3.28 \text{ ft}}{1 \text{ m}}\right) = \frac{3.28 \text{ ft/s}}{3.28 \text{ ft/s}}$
\n(c) $(1 \text{ km/h})\left(\frac{1000 \text{ m}}{1 \text{ km}}\right)\left(\frac{1 \text{ h}}{3600 \text{ s}}\right) = \frac{0.278 \text{ m/s}}{3.28 \text{ m/s}}$

21. One mile is 1.61×10^3 m. It is 110 m longer than a 1500-m race. The percentage difference is 110 m 1000 $\sqrt{7.20}$ $100\% = 7.3\%$ 1500 m

22. (a)
$$
1.00 \text{ ly} = (2.998 \times 10^8 \text{ m/s})(3.156 \times 10^7 \text{ s}) = 9.46 \times 10^{15} \text{ m}
$$

\n(b) $(1.00 \text{ ly}) \left(\frac{9.462 \times 10^{15} \text{ m}}{1.00 \text{ ly}}\right) \left(\frac{1 \text{ AU}}{1.50 \times 10^{11} \text{ m}}\right) = \frac{6.31 \times 10^4 \text{ AU}}{6.31 \times 10^4 \text{ AU}}$
\n(c) $(2.998 \times 10^8 \text{ m/s}) \left(\frac{1 \text{ AU}}{1.50 \times 10^{11} \text{ m}}\right) \left(\frac{3600 \text{ s}}{1 \text{ hr}}\right) = 7.20 \text{ AU/h}$

23. The surface area of a sphere is found by $A = 4\pi r^2 = 4\pi (d/2)^2 = \pi d^2$.

(a)
$$
A_{\text{Moon}} = \pi D_{\text{Moon}}^2 = \pi \left(3.48 \times 10^6 \text{ m} \right)^2 = \left[\frac{3.80 \times 10^{13} \text{ m}^2}{3.80 \times 10^{13} \text{ m}^2} \right]
$$

\n(b) $\frac{A_{\text{Earth}}}{A_{\text{Moon}}} = \frac{\pi D_{\text{Earth}}^2}{\pi D_{\text{Moon}}^2} = \left(\frac{D_{\text{Earth}}}{D_{\text{Moon}}} \right)^2 = \left(\frac{R_{\text{Earth}}}{R_{\text{Moon}}} \right)^2 = \left(\frac{6.38 \times 10^6 \text{ m}}{1.74 \times 10^6 \text{ m}} \right)^2 = \boxed{13.4}$

24. (a)
$$
2800 = 2.8 \times 10^3 \approx 1 \times 10^3 = \boxed{10^3}
$$

\n(b) $86.30 \times 10^2 = 8.630 \times 10^3 \approx 10 \times 10^3 = \boxed{10^4}$
\n(c) $0.0076 = 7.6 \times 10^{-3} \approx 10 \times 10^{-3} = \boxed{10^{-2}}$
\n(d) $15.0 \times 10^8 = 1.5 \times 10^9 \approx 1 \times 10^9 = \boxed{10^9}$

25. The textbook is approximately 20 cm deep and 4 cm wide. With books on both sides of a shelf, with a little extra space, the shelf would need to be about 50 cm deep. If the aisle is 1.5 meter wide, then about 1/4 of the floor space is covered by shelving. The number of books on a single shelf level is

then
$$
\frac{1}{4}
$$
 (3500 m^2) $\bigg(\frac{1 \text{ book}}{(0.25 \text{ m})(0.04 \text{ m})} \bigg) = 8.75 \times 10^4 \text{ books}$. With 8 shelves of books, the total number

of books stored is as follows.

$$
\left(8.75 \times 10^4 \frac{\text{books}}{\text{shell level}}\right) \left(8 \text{ shelves}\right) \approx \boxed{7 \times 10^5 \text{ books}}.
$$

26. The distance across the United States is about 3000 miles.

 $(3000 \text{ mi})(1 \text{ km}/0.621 \text{ mi})(1 \text{ hr}/10 \text{ km}) \approx 500 \text{ hr}$

Of course, it would take more time on the clock for the runner to run across the U.S. The runner could obviously not run for 500 hours non-stop. If they could run for 5 hours a day, then it would take about 100 days for them to cross the country.

27. An NCAA-regulation football field is 360 feet long (including the end zones) and 160 feet wide, which is about 110 meters by 50 meters, or 5,500 m^2 . The mower has a cutting width of 0.5 meters. Thus the distance to be walked is $Area = 5500 \text{ m}^2$ $11000 = 111$

$$
d = \frac{\text{Area}}{\text{width}} = \frac{5500 \text{ m}^2}{0.5 \text{ m}} = 11000 \text{ m} = 11 \text{ km}
$$

At a speed of 1 km/hr, then it will take about $\boxed{11 \text{ h}}$ to mow the field.

28. A commonly accepted measure is that a person should drink eight 8-oz. glasses of water each day. That is about 2 quarts, or 2 liters of water per day. Then approximate the lifetime as 70 years.

$$
(70 \text{ y})(365 \text{ d}/1 \text{ y})(2 \text{ L}/1 \text{ d}) \approx 5 \times 10^4 \text{ L}
$$

29. Consider the body to be a cylinder, about 170 cm tall, and about 12 cm in cross-sectional radius (a 30-inch waist). The volume of a cylinder is given by the area of the cross section times the height.

$$
V = \pi r^2 h = \pi (12 \text{ cm})^2 (170 \text{ cm}) = 9 \times 10^4 \text{ cm}^3 \approx 8 \times 10^4 \text{ cm}^3
$$

- 30. Estimate one side of a house to be about 40 feet long, and about 10 feet high. Then the wall area of that particular wall is 400 ft². There would perhaps be 4 windows in that wall, each about 3 ft wide and 4 feet tall, so 12 ft² per window, or about 50 ft² of window per wall. Thus the percentage of wall area that is window area is $\frac{50 \text{ ft}^2}{400 \text{ ft}^2} \times 100 = 12.5\%$. Thus a rough estimate would be $\boxed{10\% - 15\%}$ of 400 ft^2 . Thus a rough estimate would be $|10\% - 15\%|$ of the house's outside wall area.
- 31. Assume that the tires last for 5 years, and so there is a tread wearing of 0.2 cm/year. Assume the average tire has a radius of 40 cm, and a width of 10 cm. Thus the volume of rubber that is becoming pollution each year from one tire is the surface area of the tire, times the thickness per year that is wearing. Also assume that there are 150,000,000 automobiles in the country – approximately one automobile for every two people. So the mass wear per year is given by

$$
\left(\frac{\text{Mass}}{\text{year}}\right) = \left(\frac{\text{Surface area}}{\text{tire}}\right) \left(\frac{\text{Thickness wear}}{\text{year}}\right) \left(\text{density of rubber}\right) \left(\# \text{ of tires}\right)
$$
\n
$$
= \left[2\pi (0.4 \text{ m})(0.1 \text{ m})\right] (0.002 \text{ m/y}) \left(1200 \text{ kg/m}^3\right) \left(600,000,000 \text{ tires}\right)
$$
\n
$$
= \left[4 \times 10^8 \text{ kg/y}\right]
$$

- 32. For the equation $v = At^3 Bt$, the units of At^3 must be the same as the units of *v*. So the units of *A* must be the same as the units of v/t^3 , which would be distance time⁴. Also, the units of *Bt* must be the same as the units of *v*. So the units of *B* must be the same as the units of v/t , which would be $\left| \text{distance} / \text{time}^2 \right|$. $\text{distance}/\text{time}^2$.
- 33. (*a*) The quantity vt^2 has units of $(m/s)(s^2) = m \cdot s$, which do not match with the units of meters for *x*. The quantity 2*at* has units $(m/s^2)(s) = m/s$, which also do not match with the units of meters for *x*. Thus this equation $\boxed{\text{cannot be correct}}$.
	- (*b*) The quantity $v_0 t$ has units of $(m/s)(s) = m$, and $\frac{1}{2}at^2$ has units of $(m/s^2)(s^2) = m$. Thus, 2^{uv} has annot $\left(\frac{11}{2}\right)^{v}$ $\left(\frac{11}{2}\right)^{v}$ m. Thus, since each term has units of meters, this equation \vert can be correct \vert .
	- (*c*) The quantity $v_0 t$ has units of $(m/s)(s) = m$, and $2at^2$ has units of $(m/s^2)(s^2) = m$. Thus, since each term has units of meters, this equation $|$ can be correct
- 34. The percentage accuracy is $\frac{2 \text{ m}}{2 \times 10^{7} \text{ m}} \times 100\% = 1 \times 10^{-5}\%$. The distance of 20,000,000 m needs to $\frac{2 \text{ m}}{1 \times 10^{96}}$ = $\sqrt{1 \times 10^{-5} \%}$. The distance of 20,000,000 m needs to 2×10^7 m . The distance of 20,000,000 m needs to be distinguishable from 20,000,002 m, which means that $\frac{1}{8}$ significant figures are needed in the distance measurements.
- 35. Multiply the number of chips per wafer times the number of wafers that can be made fro a cylinder.

$$
\left(100 \frac{\text{chips}}{\text{water}}\right) \left(\frac{1 \text{ water}}{0.60 \text{ mm}}\right) \left(\frac{300 \text{ mm}}{1 \text{ cylinder}}\right) = 50,000 \frac{\text{chips}}{\text{cylinder}}
$$

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

36. (a) # of seconds in 1.00 y:
$$
1.00 y = (1.00 y) \left(\frac{3.156 \times 10^7 s}{1 y} \right) = \frac{3.16 \times 10^7 s}{3.156 \times 10^7 s}
$$

\n(b) # of nanoseconds in 1.00 y: $1.00 y = (1.00 y) \left(\frac{3.156 \times 10^7 s}{1 y} \right) \left(\frac{1 \times 10^9 ns}{1 s} \right) = \frac{3.16 \times 10^{16} ns}{3.156 \times 10^7 s}$
\n(c) # of years in 1.00 s: $1.00 s = (1.00 s) \left(\frac{1 y}{3.156 \times 10^7 s} \right) = \frac{3.17 \times 10^{-8} y}{3.17 \times 10^{-8} y}$

37. Assume that the alveoli are spherical, and that the volume of a typical human lung is about 2 liters, which is .002 m³. The diameter can be found from the volume of a sphere, $\frac{4}{3}\pi r^3$. 3^{11} *r*³.

$$
\frac{4}{3}\pi r^3 = \frac{4}{3}\pi (d/2)^3 = \frac{\pi d^3}{6}
$$

$$
(3 \times 10^8) \pi \frac{d^3}{6} = 2 \times 10^{-3} \text{ m}^3 \rightarrow d = \left[\frac{6(2 \times 10^{-3})}{3 \times 10^8 \pi} \text{ m}^3\right]^{1/3} = 2 \times 10^{-4} \text{ m}
$$

38. 1 hectare = $(1 \text{ hectare}) \left(\frac{10^4 \text{ m}^2}{10^{-4} \text{ m}^2}\right) \left(\frac{3.28 \text{ ft}}{10^{-4} \text{ m}^2}\right)^2 \left(\frac{1 \text{ acre}}{10^{-4} \text{ m}^2}\right) = 2.69 \text{ acres}$

38. 1 hectare =
$$
(1 \text{ hectare}) \left(\frac{10^4 \text{ m}^2}{1 \text{ hectare}} \right) \left(\frac{3.28 \text{ ft}}{1 \text{ m}} \right)^2 \left(\frac{1 \text{ acre}}{4 \times 10^4 \text{ ft}^2} \right) = 2.69 \text{ acres}
$$

39. (a)
$$
\left(\frac{10^{-15} \text{ kg}}{1 \text{ bacterium}}\right) \left(\frac{1 \text{ proton or neutron}}{10^{-27} \text{ kg}}\right) = \frac{10^{12} \text{ protons or neutrons}}{10^{13} \text{ kg}}
$$

\n(b) $\left(\frac{10^{-17} \text{ kg}}{1 \text{ DNA molecule}}\right) \left(\frac{1 \text{ proton or neutron}}{10^{-27} \text{ kg}}\right) = \frac{10^{10} \text{ protons or neutrons}}{10^{10} \text{ protons or neutrons}}$
\n(c) $\left(\frac{10^2 \text{ kg}}{1 \text{ human}}\right) \left(\frac{1 \text{ proton or neutron}}{10^{-27} \text{ kg}}\right) = \frac{10^{29} \text{ protons or neutrons}}{10^{27} \text{ kg}}$
\n(d) $\left(\frac{10^4 \text{ kg}}{1 \text{ galaxy}}\right) \left(\frac{1 \text{ proton or neutron}}{10^{-27} \text{ kg}}\right) = \frac{10^{68} \text{ protons or neutrons}}{10^{68} \text{ protons or neutrons}}$

40. There are about 300,000,000 people in the United States. Assume that half of them have cars, that they each drive 12,000 miles per year, and their cars get 20 miles per gallon of gasoline.

$$
(3 \times 10^8 \text{ people})
$$
 $\left(\frac{1 \text{ automobile}}{2 \text{ people}}\right) \left(\frac{12,000 \text{ mi}}{1 \text{ y}}\right) \left(\frac{1 \text{ gallon}}{20 \text{ mi}}\right) \approx \boxed{1 \times 10^{11} \text{ gallons/y}}$

- 41. Approximate the gumball machine as a rectangular box with a square cross-sectional area. In counting gumballs across the bottom, there are about 10 in a row. Thus we estimate that one layer contains about 100 gumballs. In counting vertically, we see that there are bout 15 rows. Thus we estimate that there are about $|1500 \text{ gumballs}|$ in the machine.
- 42. The volume of water used by the people can be calculated as follows:

$$
(4 \times 10^4 \text{ people}) \left(\frac{1200 \text{ L/day}}{4 \text{ people}}\right) \left(\frac{365 \text{ day}}{1 \text{ y}}\right) \left(\frac{1000 \text{ cm}^3}{1 \text{ L}}\right) \left(\frac{1 \text{ km}}{10^5 \text{ cm}}\right)^3 = 4.4 \times 10^{-3} \text{ km}^3/\text{y}
$$

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The depth of water is found by dividing the volume by the area.

$$
d = \frac{V}{A} = \frac{4.4 \times 10^{-3} \text{ km}^3/\text{y}}{50 \text{ km}^2} = \left(8.76 \times 10^{-5} \frac{\text{km}}{\text{y}}\right) \left(\frac{10^5 \text{ cm}}{1 \text{ km}}\right) = 8.76 \text{ cm}/\text{y} \approx \boxed{9 \text{ cm}/\text{y}}
$$

43. The volume of a sphere is given by $V = \frac{4}{3}\pi r^3$. For our 1-ton rock, we can calculate the volume to be $(2000 \text{ lb}) \left(16^3 \text{ N} \right)$

$$
V = (1 \text{ T}) \left(\frac{2000 \text{ lb}}{1 \text{ T}} \right) \left(\frac{1 \text{ ft}^3}{186 \text{ lb}} \right) = 10.8 \text{ ft}^3.
$$

Then the radius is found by \int_{0}^{3} $(1 + 3)^{-1/3}$

$$
d = 2r = 2\left(\frac{3V}{4\pi}\right)^{1/3} = 2\left[\frac{3\left(10.8 \text{ ft}^3\right)}{4\pi}\right]^{1/3} = 2.74 \text{ ft} \approx \boxed{3 \text{ ft}}
$$

44. To calculate the mass of water, we need to find the volume of water, and then convert the volume to mass.

$$
\left[\left(4 \times 10^{1} \text{ km}^{2} \right) \left(\frac{10^{5} \text{cm}}{1 \text{ km}} \right)^{2} \right] (1.0 \text{ cm}) \left(\frac{10^{-3} \text{kg}}{1 \text{ cm}^{3}} \right) \left(\frac{1 \text{ ton}}{10^{3} \text{kg}} \right) = \boxed{4 \times 10^{5} \text{ton}}
$$

To find the number of gallons, convert the volume to gallons.

$$
\left[\left(4 \times 10^{1} \text{ km}^{2} \right) \left(\frac{10^{5} \text{cm}}{1 \text{ km}} \right)^{2} \right] (1.0 \text{ cm}) \left(\frac{1 \text{ L}}{1 \times 10^{3} \text{ cm}^{3}} \right) \left(\frac{1 \text{ gal}}{3.78 \text{ L}} \right) = 10^{8} \text{ gal}
$$

45. A pencil has a diameter of about 0.7 cm. If held about 0.75 m from the eye, it can just block out the Moon. The ratio of pencil diameter to arm length is the same as the ratio of Moon diameter to Moon distance. From the diagram, we have the following ratios.

46. The person walks 4 km/h , 10 hours each day. The radius of the Earth is about 6380 km, and the distance around the world at the equator is the circumference, $2\pi R_{\text{Earth}}$. We assume that the person can "walk on water", and so ignore the existence of the oceans.

$$
2\pi \left(6380 \text{ km}\right) \left(\frac{1 \text{ h}}{4 \text{ km}}\right) \left(\frac{1 \text{ d}}{10 \text{ h}}\right) = \boxed{1 \times 10^3 \text{ d}}
$$

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

47. A cubit is about a half of a meter, by measuring several people's forearms. Thus the dimensions of Noah's ark would be $\boxed{150 \text{ m} \log 25 \text{ m} \text{ wide}, 15 \text{ m} \text{ high}}$. The volume of the ark is found by multiplying the three dimensions.

$$
V = (150 \text{ m})(25 \text{ m})(15 \text{ m}) = 5.625 \times 10^4 \text{ m}^3 \approx \boxed{6 \times 10^4 \text{ m}^3}
$$

48. The volume of the oil will be the area times the thickness. The area is $\pi r^2 = \pi (d/2)^2$, and so e area is $\pi r^2 = \pi (d/2)^2$, and so

$$
V = \pi (d/2)^{2} t \rightarrow d = 2 \sqrt{\frac{V}{\pi t}} = 2 \sqrt{\frac{1000 \text{cm}^{3} \left(\frac{1 \text{ m}}{100 \text{ cm}}\right)^{3}}{\pi \left(2 \times 10^{-10} \text{ m}\right)}} = \boxed{3 \times 10^{3} \text{ m}}.
$$

49. Consider the diagram shown. *L* is the distance she walks upstream, which is about 120 yards. Find the distance across the river from the diagram.

$$
\tan 60^\circ = \frac{d}{L} \to d = L \tan 60^\circ = (120 \text{ yd}) \tan 60^\circ = 210 \text{ yd}
$$

$$
(210 \text{ yd}) \left(\frac{3 \text{ ft}}{1 \text{ yd}}\right) \left(\frac{0.305 \text{ m}}{1 \text{ ft}}\right) = 190 \text{ m}
$$

$$
d \sum_{\substack{60^{\circ} \\ L}}
$$

50.
$$
\left(\frac{8 \text{ s}}{1 \text{ y}}\right)\left(\frac{1 \text{ y}}{3.156 \times 10^7 \text{ s}}\right) \times 100\% = 3 \times 10^{-5}\%
$$

51. The volume of a sphere is found by
$$
V = \frac{4}{3}\pi r^3
$$
.
\n
$$
V_{\text{Moon}} = \frac{4}{3}\pi R_{\text{Moon}}^3 = \frac{4}{3}\pi \left(1.74 \times 10^6 \text{ m}\right)^3 = 2.21 \times 10^{19} \text{ m}^3
$$
\n
$$
\frac{V_{\text{Earth}}}{V_{\text{Moon}}} = \frac{\frac{4}{3}\pi R_{\text{Earth}}^3}{\frac{4}{3}\pi R_{\text{Moon}}^3} = \left(\frac{R_{\text{Earth}}}{R_{\text{Moon}}}\right)^3 = \left(\frac{6.38 \times 10^6 \text{ m}}{1.74 \times 10^6 \text{ m}}\right)^3 = 49.3
$$

Thus it would take about $\left[49.3\right]$ Moons to create a volume equal to that of the Earth.

52. (a)
$$
1.0 \text{ Å} = \left(1.0 \text{ Å}\right) \left(\frac{10^{-10} \text{ m}}{1 \text{ Å}}\right) \left(\frac{1 \text{ nm}}{10^{-9} \text{ m}}\right) = \boxed{0.10 \text{ nm}}
$$

\n(b) $1.0 \text{ Å} = \left(1.0 \text{ Å}\right) \left(\frac{10^{-10} \text{ m}}{1 \text{ Å}}\right) \left(\frac{1 \text{ fm}}{10^{-15} \text{ m}}\right) = \boxed{1.0 \times 10^5 \text{ fm}}$
\n(c) $1.0 \text{ m} = (1.0 \text{ m}) \left(\frac{1 \text{ Å}}{10^{-10} \text{ m}}\right) = \boxed{1.0 \times 10^{10} \text{ Å}}$
\n(d) $1.0 \text{ ly} = (1.0 \text{ ly}) \left(\frac{9.46 \times 10^{15} \text{ m}}{1 \text{ ly}}\right) \left(\frac{1 \text{ Å}}{10^{-10} \text{ m}}\right) = \boxed{9.5 \times 10^{25} \text{ Å}}$

53. (*a*) Note that $\sin 15.0^{\circ} = 0.259$ and $\sin 15.5^{\circ} = 0.267$. $\sin 15.5^{\circ} = 0.267$.

$$
\left(\frac{\Delta\theta}{\theta}\right)100 = \left(\frac{0.5^{\circ}}{15.0^{\circ}}\right)100 = 3\%
$$
\n
$$
\left(\frac{\Delta\sin\theta}{\sin\theta}\right)100 = \left(\frac{8 \times 10^{-3}}{0.259}\right)100 = 3\%
$$

(*b*) Note that $\sin 75.0^{\circ} = 0.966$ and $\sin 75.5^{\circ} = 0.968$. $\sin 75.5^{\circ} = 0.968$.

$$
\left(\frac{\Delta\theta}{\theta}\right)100 = \left(\frac{0.5^{\circ}}{75.0^{\circ}}\right)100 = \boxed{0.7\%}
$$
\n
$$
\left(\frac{\Delta\sin\theta}{\sin\theta}\right)100 = \left(\frac{2 \times 10^{-3}}{0.966}\right)100 = \boxed{0.2\%}
$$

A consequence of this result is that when using a protractor, and you have a fixed uncertainty in the angle ($\pm 0.5^\circ$ in this case), you should measure the angles from a reference line that gives a large angle measurement rather than a small one. Note above that the angles around 75° had only a 0.2% error in sin θ , while the angles around 15[°] had a 3% error in sin θ .

54. Utilize the fact that walking totally around the Earth along the meridian would trace out a circle whose full 360° would equal the circumference of the Earth. would equal the circumference of the Earth.
 $(1^{\circ})^{\circ} (2\pi (6.38 \times 10^{3} \text{km}))$ (0.621 m)

$$
(1 \text{ minute})\left(\frac{1^{\circ}}{60 \text{ minute}}\right)\left(\frac{2\pi (6.38 \times 10^3 \text{ km})}{360^{\circ}}\right)\left(\frac{0.621 \text{ m}}{1 \text{ km}}\right) = 1.15 \text{ mi}
$$

CHAPTER 2: Describing Motion: Kinematics in One Dimension

Answers to Questions

- 1. A car speedometer measures only speed. It does not give any information about the direction, and so does not measure velocity.
- 2. By definition, if an object has a constant velocity, then both the object's speed and its direction of motion are constant. Therefore the object CANNOT have a varying speed if its velocity is constant.
- 3. When an object moves with constant velocity, its average velocity over any time interval is exactly equal to its instantaneous velocity at all times
- 4. For both cars, the time elapsed is the distance traveled divided by the average velocity. Since both cars travel the same distance, the car \boldsymbol{v} with the larger average velocity will have the smaller elapsed time. Consider this scenario. Assume that one car has a constant acceleration down the track. Then a graph of its speed versus time \overline{t} \overline{t} \overline{t} would look like line "*A*" on the first graph. The shaded area of the graph represents the distance traveled, and the graph is plotted to such a time that the shaded area represents the length of the track. The time for this car to finish the race is labeled $"t_1"$.

Now let the second car have a much smaller acceleration initially, but V with an increasing acceleration. A graph of its velocity, superimposed on the above graph and labeled B ", might look like $time$ the second diagram.

It is seen that at the time t_1 when the first car finished the race, the second car is going faster than the first car, because the heavy line is "higher" on the graph than the line representing the first car. However, the area under the "B" line (the distance that the second car has traveled) is smaller than the shaded area, and so is less than ψ the full track length. For the area under the "B" line to be the same as the area under the "A" line, the graph would need to look like the third diagram, indicating a longer time for the second car to finish $time$ $time$ the race.

5. There is no general relationship between the magnitude of speed and the magnitude of acceleration. For example, one object may have a large but constant speed. The acceleration of that object is then 0. Another object may have a small speed but be gaining speed, and therefore have a positive acceleration. So in this case the object with the greater speed has the lesser acceleration.

Or consider two objects that are dropped from rest at different times. If we ignore air resistance, then the object dropped first will always have a greater speed than the object dropped second, but both will have the same acceleration of 9.80 m/s². . A construction of the constr
A construction of the construc

6. The acceleration of both the motorcycle and the bicycle are the same, since the same change in velocity occurred during the same time interval.

If you do a further calculation, you will find that the distance traveled by the motorcycle during the acceleration is 17 times the distance traveled by the bicycle.

- 7. If an object is traveling to the north but slowing down, it has a northward velocity and a southward acceleration.
- 8. The velocity of an object can be negative when its acceleration is positive. If we define the positive direction to be to the right, then an object traveling to the left that is having a reduction in speed will have a negative velocity with a positive acceleration.

If again we define the positive direction to be to the right, then an object traveling to the right that is having a reduction in speed will have a positive velocity and a negative acceleration.

- 9. If north is defined as the positive direction, then an object traveling to the south and increasing in speed has both a negative velocity and a negative acceleration. Or, if up is defined as the positive direction, then an object falling due to gravity has both a negative velocity and a negative acceleration.
- 10. If the two cars emerge side by side, then the one moving faster is passing the other one. Thus car A is passing car B. With the acceleration data given for the problem, the ensuing motion would be that car A would pull away from car B for a time, but eventually car B would catch up to and pass car A.
- 11. Assume that north is the positive direction. If a car is moving south and gaining speed at an increasing rate, then the acceleration will be getting larger in magnitude. However, since the acceleration is directed southwards, the acceleration is negative, and is getting more negative. That is a decreasing acceleration as the speed increases.

Another example would be an object falling WITH air resistance. As the object falls, it gains speed, the air resistance increases. As the air resistance increases, the acceleration of the falling object decreases, and it gains speed less quickly the longer it falls.

- 12. Assuming that the catcher catches the ball at the same height at which it left the bat, then the ball will be traveling with a speed of 120 km/h when caught. This is proven in problem 41.
- 13. As a freely falling object speeds up, its acceleration due to gravity stays the same. If air resistance is considered, then the acceleration of the object is due to both gravity and air resistance. The total acceleration gets smaller as the object speeds up, until the object reaches a terminal velocity, at which time its total acceleration is zero. Thereafter its speed remains constant.
- 14. To estimate the height, throw the ball upward and time the flight from throwing to catching. Then, ignoring air resistance, the time of rising would be half of the time of flight. With that "half" time, assuming that the origin is at the top of the path and that downward is positive, knowing that the ball started from the top of the path with a speed of 0, use the equation $y = \frac{1}{2}gt^2$ with that time and the $2\delta'$ while the time and the acceleration due to gravity to find the distance that the ball fell. With the same "half" time, we know that at the top of the path, the speed is 0. Taking the upward direction as positive, use the equation $v = v_0 + at \rightarrow 0 = v_0 - gt \rightarrow v_0 = gt$ to find the throwing speed.
- 15. The average speed is NOT 80 km/h. Since the two distances traveled were the same, the times of travel were unequal. The time to travel from A to B at 70 km/h is longer than the time to travel from B to C at 90 km/h. Thus we cannot simply average the speed numbers. To find the average speed, we need to calculate (total distance) / (total time). We assume the distance from A to B and the distance from B to C are both *d* km. The time to travel a distance *d* with a speed *v* is $t = d/v$.

$$
\overline{v} = \frac{d_{AB} + d_{BC}}{t_{AB} + t_{BC}} = \frac{(d \text{ km}) + (d \text{ km})}{\frac{d \text{ km}}{70 \text{ km/h}} + \frac{d \text{ km}}{90 \text{ km/h}}} = 78.75 \text{ km/h}.
$$
 The average speed is 78.75 km/h.

16. The sounds will not occur at equal time intervals because the longer any particular nut falls, the faster it will be going. With equal distances between nuts, each successive nut, having fallen a longer time when its predecessor reaches the plate, will have a higher average velocity and thus travel the inter-nut distance in shorter periods of time. Thus the sounds will occur with smaller and smaller intervals between sounds.

To hear the sounds at equal intervals, the nuts would have to be tied at distances corresponding to equal time intervals. Since for each nut the distance of fall and time of fall are related by $d_i = \frac{1}{2}gt_i^2$, equal time intervals. Since for each nut the distance of fall and time of fall are related by $d_i = \frac{1}{2}gt_i^2$, assume that $d_1 = \frac{1}{2}gt_i^2$. If we want $t_2 = 2t_1$, $t_3 = 3t_1$, $t_4 = 4t_1$, \cdots , then $d_2 = \frac{1}{2}g(2t$ $\frac{1}{2}a(2t)^2 = Ad$ 2^2 2 8 2^2 1 1^2 1^2 1^2 $d_3 = \frac{1}{2}g(3t_1)^2 = 9d_1$, $d_4 = \frac{1}{2}g(4t_1)^2 = 16d_1$, etc. $3\frac{1}{3}$ 2 6 (34) $\frac{1}{2}$ 6 (34) $\frac{1}{4}$ $\frac{1}{2}$ 6 (34) $\frac{1}{2}$ 10 $\frac{1}{4}$. Out. $\frac{1}{2}a(t^2-16d$ atc $4 - 28$ (π_1) -1 0 μ_1 , 0 cc. $d_4 = \frac{1}{2}g(4t_1)^2 = 16d_1$, etc.

17. The elevator moving from the second floor to the fifth floor is NOT an example of constant acceleration. The elevator accelerates upward each time it starts to move, and it accelerates downward each time it stops.

Ignoring air resistance, a rock falling from a cliff would have a constant acceleration. (If air resistance is included, then the acceleration will be decreasing as the rock falls.) A dish resting on a table has an acceleration of 0, so the acceleration is constant.

- 18. As an object rises WITH air resistance, the acceleration is larger in magnitude than *g*, because both gravity and air resistance will be causing a downward acceleration. As the object FALLS with air resistance, the acceleration will be smaller in magnitude than *g*, because gravity and resistance will be opposing each other. Because of the smaller acceleration being applied over the same distance, the return speed will be slower than the launch speed.
- 19. If an object is at the instant of reversing direction (like an object thrown upward, at the top of its path), it instantaneously has a zero velocity and a non-zero acceleration at the same time. A person at the exact bottom of a "bungee" cord plunge also has an instantaneous velocity of zero but a non zero (upward) acceleration at the same time.
- 20. An object moving with a constant velocity has a non-zero velocity and a zero acceleration at the same time. So a car driving at constant speed on a straight, level roadway would meet this condition.
- $\frac{d^2}{dt^2} = \frac{1}{2\pi} \frac{1}{(1+\alpha)^2} = \frac{1}{2\pi} \frac{1}{(1+\alpha)^2} = 78.75 \text{ km/h}$. The average speed is 78.75 km/h.

will associate a bulletime interest is because the longer any particular ant falls the same set of the same set of 21. The object starts with a constant velocity in the positive direction. At about *t* = 17 s, when the object is at the 5 meter position, it begins to gain speed – it has a positive acceleration. At about $t = 27$ s, when the object is at about the 12 m position, it begins to slow down – it has a negative acceleration. The object instantaneously stops at about $t = 37$ s, reaching its maximum distance from the origin of 20 m. The object then reverses direction, gaining speed while moving backwards. At about $t = 47$ s, when the object is again at about the 12 m position, the object starts to slow down, and appears to stop at $t = 50$ s, 10 m from the starting point.
- 22. Initially, the object moves in the positive direction with a constant acceleration, until about $t = 45$ s, when it has a velocity of about 37 m/s in the positive direction. The acceleration then decreases, reaching an instantaneous acceleration of 0 at about $t = 50$ s, when the object has its maximum speed of about 38 m/s. The object then begins to slow down, but continues to move in the positive

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

direction. The object stops moving at $t = 90$ s and stays at rest until about $t = 108$ s. Then the object begins to move to the right again, at first with a large acceleration, and then a lesser acceleration. At the end of the recorded motion, the object is still moving to the right and gaining speed.

Solutions to Problems

1. The average speed is given by:

 $\overline{v} = d/\Delta t = 235$ km/3.25 h = $\sqrt{72.3 \text{ km/h}}$.

- 2. The time of travel can be found by rearranging the average speed equation. $\overline{v} = d/\Delta t \rightarrow \Delta t = d/\overline{v} = (15 \text{ km})/(25 \text{ km/h}) = 0.60 \text{ h} = 36 \text{ min}$
- 3. The distance of travel (displacement) can be found by rearranging the average speed equation. Also note that the units of the velocity and the time are not the same, so the speed units will be converted.

$$
\overline{v} = \frac{d}{\Delta t} \rightarrow d = \overline{v} \Delta t = (110 \text{ km/h}) \left(\frac{1 \text{ h}}{3600 \text{ s}}\right) (2.0 \text{ s}) = 0.061 \text{ km} = \boxed{61 \text{ m}}
$$

4. (a)
$$
35 \text{ mi/h} = (35 \text{ mi/h})(1.61 \text{ km/min}) = 56 \text{ km/h}
$$

(b)
$$
35 \text{ mi/h} = (35 \text{ mi/h})(1610 \text{ m/min})(1 \text{ h}/3600 \text{ s}) = 16 \text{ m/s}
$$

(c) $35 \text{ mi/h} = (35 \text{ mi/h})(5280 \text{ ft/min})(1 \text{ h}/3600 \text{ s}) = 51 \text{ ft/s}$

5. The average velocity is given by
$$
\overline{v} = \frac{\Delta x}{\Delta t} = \frac{-4.2 \text{ cm} - 3.4 \text{ cm}}{6.1 \text{ s} - 3.0 \text{ s}} = \frac{-7.6 \text{ cm}}{3.1 \text{ s}} = \boxed{-2.5 \text{ cm/s}}.
$$

6. The average velocity is given by $\overline{v} = \frac{\Delta x}{\Delta x} = \frac{8.5 \text{ cm} - 3.4 \text{ cm}}{1.5 \text{ cm/s}} = \frac{5.1 \text{ cm}}{0.78 \text{ cm/s}}$. 0.78 cm/s . $4.5 s - (-2.0 s)$ 6.5s $\overline{v} = \frac{\Delta x}{v} = \frac{8.5 \text{ cm} - 3.4 \text{ cm}}{1.5 \text{ cm} \cdot \text{s}} = \frac{5.1 \text{ cm}}{1.78 \text{ cm/s}} = 0.78 \text{ cm/s}.$ $t = 4.5 s - (-2.0 s)$ 6.5s The average velocity is given by $\overline{v} = \frac{2v}{\Delta t} = \frac{60 \text{ cm}^2}{4.5 \text{ s} - (-2.0 \text{ s})} = \frac{61 \text{ cm}}{6.5 \text{ s}} = \frac{0.78 \text{ cm/s}}{6.5 \text{ s}}.$
The average speed cannot be calculated. To calculate the average speed, we would need to kn

actual distance traveled, and it is not given.

7. The time for the first part of the trip is calculated from the initial speed and the first distance.
ave speed, = $v_1 = \frac{d_1}{dt_1} \rightarrow \Delta t_1 = \frac{d_1}{dt_2} = \frac{130 \text{ km}}{1.37 \text{ h}} = 1.37 \text{ h} = 82 \text{ min}$

ave speed₁ =
$$
v_1 = \frac{d_1}{\Delta t_1} \rightarrow \Delta t_1 = \frac{d_1}{v_1} = \frac{130 \text{ km}}{95 \text{ km/h}} = 1.37 \text{ h} = 82 \text{ min}
$$

The time for the second part of the trip is therefore

 $t_2 = \Delta t_{tot} - \Delta t_1 = 3.33 \text{ h} - 1.37 \text{ h} = 1.96 \text{ h} = 118 \text{ min}$

The distance for the second part of the trip is calculated from the average speed for that part of the trip and the time for that part of the trip.

ave speed₂ =
$$
v_2 = \frac{d_2}{\Delta t_2} \rightarrow d_2 = v_2 \Delta t_2 = (65 \text{ km/h})(1.96 \text{ h}) = 127.5 \text{ km} = 1.3 \times 10^2 \text{ km}
$$

(*a*) The total distance is then $d_{total} = d_1 + d_2 = 130 \text{ km} + 127.5 \text{ km} = 257.5 \text{ km} \approx 2.6 \times 10^2 \text{ km}$

(*b*) The average speed is NOT the average of the two speeds. Use the definition of average speed.

$$
ave speed = \frac{d_{total}}{\Delta t_{total}} = \frac{257.5 \text{ km}}{3.33 \text{ h}} = \boxed{77 \text{ km/h}}
$$

8. The speed of sound is intimated in the problem as 1 mile per 5 seconds. The speed is calculated by:

$$
speed = \frac{distance}{time} = \left(\frac{1\,\text{mi}}{5\,\text{s}}\right) \left(\frac{1610\,\text{m}}{1\,\text{mi}}\right) = \boxed{300\,\text{m/s}}.
$$

Note that only 1 significant figure is given, (5 sec), and so only 1 significant figure is justified in the result.

9. The distance traveled is 2.0 miles $(8 \text{ laps} \times 0.25 \text{ mi}/\text{lap})$. The displacement is 0 because the ending point is the same as the starting point.

(a) Average speed =
$$
\frac{d}{\Delta t} = \frac{2.0 \text{ mi}}{12.5 \text{ min}} = \left(\frac{2 \text{ mi}}{12.5 \text{ min}}\right) \left(\frac{1610 \text{ m}}{1 \text{ mi}}\right) \left(\frac{1 \text{ min}}{60 \text{ s}}\right) = \boxed{4.3 \text{ m/s}}
$$

(b) Average velocity = $\overline{v} = \frac{\Delta x}{\Delta t} = \boxed{0 \text{ m/s}}$

10. The distance traveled is 116 km + $\frac{1}{2}$ (116 km) = 174 km, and the displacement is ce traveled is 116 km $+\frac{1}{2}(116 \text{ km}) = 174 \text{ km}$, and the displacement is $\frac{1}{16}(116 \text{ km}) = 58 \text{ km}$. The total time is 14.0 s + 4.8 s = 18.8 s $116 \text{ km} - \frac{1}{2}(116 \text{ km}) = 58 \text{ km}$. The total time is $14.0 \text{ s} + 4.8 \text{ s} = 18.8 \text{ s}$.

(a) Average speed =
$$
\frac{d}{\Delta t} = \frac{174 \text{ m}}{18.8 \text{ s}} = \boxed{9.26 \text{ m/s}}
$$

(b) Average velocity = $\overline{v} = \frac{\Delta x}{\Delta t} = \frac{58 \text{ m}}{18.8 \text{ s}} = \boxed{3.1 \text{ m/s}}$

11. Since the locomotives have the same speed, they each travel half the distance, 4.25 km. Find the time of travel from the average speed.

$$
\text{ave speed} = v = \frac{d}{\Delta t} \to \Delta t = \frac{d}{v} = \frac{4.25 \text{ km}}{95 \text{ km/h}} = 0.0447 \text{ h} \left(\frac{60 \text{ min}}{1 \text{ h}} \right) = 2.68 \text{ min} \approx 2.7 \text{ min}
$$

12. Both objects will have the same time of travel. If the truck travels a distance d_{max} , then the distance the car travels will be $d_{\text{car}} = d_{\text{track}} + 110 \text{ m}$. Using the equation for average speed, $\overline{v} = d/\Delta t$, solve for time, and equate the two times.

$$
\Delta t = \frac{d_{\text{truck}}}{\overline{v}_{\text{truck}}} = \frac{d_{\text{car}}}{\overline{v}_{\text{car}}} \qquad \frac{d_{\text{truck}}}{75 \text{ km/h}} = \frac{d_{\text{track}} + 110 \text{ m}}{88 \text{ km/h}}
$$

Solving for d_{true} gives $d_{\text{true}} = (110 \text{ m}) \frac{(100 \text{ km/s})^2}{(0.0 \text{ km/s}^2)(1.751 \text{ m/s}^2)} = 634.6 \text{ m}.$ 75 km/h) $88 \text{ km/h} - 75 \text{ km/h}$)

The time of travel is

$$
\Delta t = \frac{d_{\text{tuck}}}{\overline{v}_{\text{tuck}}} = \left(\frac{634.6 \text{ m}}{75000 \text{ m/h}}\right) \left(\frac{60 \text{ min}}{1 \text{ h}}\right) = 0.5077 \text{ min} = 30.46 \text{ s} = \boxed{3.0 \times 10^1 \text{ s}}.
$$

Also note that $\Delta t = \frac{d_{\text{car}}}{\overline{v}_{\text{car}}} = \left(\frac{634.6 \text{ m} + 110 \text{ m}}{88000 \text{ m/h}}\right) \left(\frac{60 \text{ min}}{1 \text{ h}}\right) = 0.5077 \text{ min} = 30.46 \text{ s}.$
ALTERNATE SOLUTION:

The speed of the car relative to the truck is 88 km/h – 75 km/h = 13 km/h. In the reference frame of the truck, the car must travel 110 m to catch it.

$$
\Delta t = \frac{0.11 \text{ km}}{13 \text{ km/h}} \left(\frac{3600 \text{ s}}{1 \text{ h}} \right) = 30.46 \text{ s}
$$

13. The average speed for each segment of the trip is given by $\bar{v} = \frac{d}{v}$, so $\Delta t = \frac{d}{v}$ for each segment. $t \rightarrow \overline{v}$, so $\Delta t = \frac{a}{\epsilon}$ for each segment. *d v* \overline{v}

For the first segment,
$$
\Delta t_1 = \frac{d_1}{\overline{v_1}} = \frac{3100 \text{ km}}{790 \text{ km/h}} = 3.924 \text{ h}.
$$

For the second segment, $\Delta t_2 = \frac{\mu_2}{\sigma} = \frac{2800 \text{ km}}{000 \text{ Hz}} = 2.828 \text{ h}.$ 2 \sim \sim $\frac{1}{2}$ 2800 km 2000. 2.828 h 990 km/h $t_1 = \frac{d_2}{dt} = \frac{2800 \text{ km}}{t} = 2.828 \text{ h}.$ \overline{v} , 990 km/h For the second segment, $\Delta t_2 = \frac{\Delta t_2}{v_2} = \frac{2600 \text{ km}}{990 \text{ km/h}} = 2.828 \text{ h}.$
Thus the total time is $\Delta t_{\text{tot}} = \Delta t_1 + \Delta t_2 = 3.924 \text{ h} + 2.828 \text{ h} = 6.752 \text{ h} \approx 6.8 \text{ h}.$

Thus the total time is $\Delta t_{\text{tot}} = \Delta t_1 + \Delta t_2 = 3.924 \text{ h} + 2.828 \text{ h} = 6.752 \text{ h} \approx 6.8 \text{ h}.$

The average speed of the plane for the entire trip is
\n
$$
\overline{v} = \frac{d_{tot}}{\Delta t_{tot}} = \frac{3100 \text{ km} + 2800 \text{ km}}{6.752 \text{ h}} = 873.8 \approx 8.7 \times 10^2 \text{ km/h}.
$$

- 14. The distance traveled is 500 km (250 km outgoing, 250 km return, keep 2 significant figures). The displacement (Δx) is 0 because the ending point is the same as the starting point.
	- (*a*) To find the average speed, we need the distance traveled (500 km) and the total time elapsed.

During the outgoing portion, $\overline{v_1} = \frac{u_1}{v_1}$ and so $\Delta t_1 = \frac{u_1}{c} = \frac{250 \text{ nm}}{251 \text{ kg}} = 2.632 \text{ h}$. During the return $\frac{1}{1}$ $\frac{1}{1}$ $\frac{1}{1}$ $\frac{1}{1}$ $\overline{v_i} = \frac{d_i}{v}$ and so $\Delta t_i = \frac{d_i}{v} = \frac{250 \text{ km}}{t} = 2.632 \text{ h}$. During the return $t_{\rm i}$ $\overline{v_{\rm i}}$ 95 km/h and so $\Delta t_1 = \frac{a_1}{\Delta t_1} = \frac{256 \text{ km}}{251 \text{ Hz}} = 2.632 \text{ h}$. During the return $\frac{1}{1}$ 20 $\frac{1}{1}$ $\frac{250 \text{ km}}{l}$ = 2.632 h. During the return 95 km/h $t_i = \frac{d_i}{t} = \frac{250 \text{ km}}{t} = 2.632 \text{ h}$. During the return $\overline{v_1}$ 95 km/h . During the return portion, $\overline{v_2} = \frac{u_2}{v_1}$, and so $\Delta t_2 = \frac{u_2}{\Delta t_2} = \frac{256 \text{ km}}{251 \text{ Hz}} = 4.545 \text{ h}$. Thus the total time, including lunch, is $\overline{v}_2 = \frac{d_2}{dt}$, and so $\Delta t_2 = \frac{d_2}{dt} = \frac{250 \text{ km}}{554.5 \text{ km}} = 4.545 \text{ h}$. Thus the total time, including lunch, is $t_1 = \frac{d_2}{dt} = \frac{250 \text{ km}}{t} = 4.545 \text{ h}$. Thus the total time, including lunch, is

portion,
$$
\overline{v}_2 = \frac{a_2}{\Delta t_2}
$$
, and so $\Delta t_2 = \frac{a_2}{\overline{v}_2} = \frac{256 \text{ nm}}{55 \text{ km/h}} = 4.545 \text{ h}$. Thus the total time, including lunch, is

$$
\Delta t_{\text{total}} = \Delta t_1 + \Delta t_{\text{lunch}} + \Delta t_2 = 8.177 \text{ h}
$$
. Average speed = $\frac{d_{\text{total}}}{\Delta t_{\text{total}}} = \frac{500 \text{ km}}{8.177 \text{ h}} = \boxed{61 \text{ km/h}}$.

(b) Average velocity =
$$
\sqrt{\frac{v}{v}} = \frac{\Delta x}{\Delta t} = 0
$$

15. The average speed of sound is given by $\overline{v} = d/\Delta t$, and so the time for the sound to travel from the end of the lane back to the bowler is $\Delta t_{\text{sound}} = \frac{a}{\Delta t_0} = \frac{10.5 \text{ m}}{240 \text{ s}} = 4.85 \times 10^{-2} \text{ s}$. Thus the time for the $\frac{1}{2}$ $\frac{16.5 \text{ m}}{4.85 \times 10^{-2} \text{ s}}$. Thus the time for the 340 m/s $t_{\text{sound}} = \frac{d}{\epsilon} = \frac{16.5 \text{ m}}{10^{-3} \text{ s}} = 4.85 \times 10^{-2} \text{ s}.$ Thus the time for the $\overline{v}_{\rm sound}$ 340 m/s . Thus the time for the ball to travel from the bowler to the end of the lane is given by $t_{\text{ball}} = \Delta t_{\text{total}} - \Delta t_{\text{sound}} = 2.50 \text{ s} - 4.85 \times 10^{-2} \text{ s} = 2.4515 \text{ s}$. And so the speed of the ball is:

$$
\overline{v}_{\text{ball}} = \frac{d}{\Delta t_{\text{ball}}} = \frac{16.5 \text{ m}}{2.4515 \text{ s}} = \boxed{6.73 \text{ m/s}}.
$$

16. The average acceleration is given by
\n
$$
\overline{a} = \frac{\Delta v}{\Delta t} = \frac{95 \text{ km/h} - 0 \text{ km/h}}{6.2 \text{ s}} = \frac{(95 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}}\right)}{6.2 \text{ s}} = \boxed{4.3 \text{ m/s}^2}.
$$

17. (a) The average acceleration of the sprinter is
$$
\bar{a} = \frac{\Delta v}{\Delta t} = \frac{10.0 \text{ m/s} - 0.0 \text{ m/s}}{1.35 \text{ s}} = \boxed{7.41 \text{ m/s}^2}
$$
.
\n(b) $\bar{a} = (7.41 \text{ m/s}^2) \left(\frac{1 \text{ km}}{1000 \text{ m}}\right) \left(\frac{3600 \text{ s}}{1 \text{ h}}\right)^2 = \boxed{9.60 \times 10^4 \text{ km/h}^2}$

18. The time can be found from the average acceleration, $\bar{a} = \frac{\Delta v}{\Delta x}$. $\overline{a} = \overline{a}$. *t* .

$$
\Delta t = \frac{\Delta v}{\overline{a}} = \frac{110 \text{ km/h} - 80 \text{ km/h}}{1.6 \text{ m/s}^2} = \frac{(30 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}}\right)}{1.6 \text{ m/s}^2} = 5.2 \text{ s}
$$

19. The initial velocity of the car is the average speed of the car before it accelerates.

$$
\overline{v} = \frac{d}{\Delta t} = \frac{110 \text{ m}}{5.0 \text{ s}} = 22 \text{ m/s} = v_0
$$

The final speed is $v = 0$, and the time to stop is 4.0 s. Use Eq. 2-11a to find the acceleration.

$$
v = v_0 + at \rightarrow
$$

$$
a = \frac{v - v_0}{t} = \frac{0 - 22 \text{ m/s}}{4.0 \text{ s}} = \boxed{-5.5 \text{ m/s}^2} = \left(-5.5 \text{ m/s}^2\right) \left(\frac{1 g}{9.80 \text{ m/s}^2}\right) = \boxed{-0.56 g \text{'s}}
$$

20. To estimate the velocity, find the average velocity over each time interval, and assume that the car had that velocity at the midpoint of the time interval. To estimate the acceleration, find the average acceleration over each time interval, and assume that the car had that acceleration at the midpoint of the time interval. A sample of each calculation is shown. $0.625 \t 2.40$

$$
t_{\text{mid}} = \frac{2.50 \text{ s} + 2.00 \text{ s}}{2} = 2.25 \text{ s}
$$

\n
$$
\overline{v} = \frac{\Delta x}{\Delta t} = \frac{13.79 \text{ m} - 8.55 \text{ m}}{2.50 \text{ s} - 2.00 \text{ s}} = \frac{5.24 \text{ m}}{0.50 \text{ s}} = 10.48 \text{ m/s}
$$

\n1.50 4.62
\n1.50 4.62
\n1.25 5.36
\n2.25 10.48
\n2.25 10.48
\n2.25 10.48
\n2.25 10.48

From 2.25 s to 2.75 s, for average acceleration:

$$
t_{\text{mid}} = \frac{2.25 \text{ s} + 2.75 \text{ s}}{2} = 2.50 \text{ s}
$$

$$
\overline{a} = \frac{\Delta v}{\Delta t} = \frac{13.14 \text{ m/s} - 10.48 \text{ m/s}}{2.75 \text{ s} - 2.25 \text{ s}} = \frac{2.66 \text{ m/s}}{0.50 \text{ s}} = 5.32 \text{ m/s}^2
$$

$$
t_{\text{mid}} = \frac{3.00 - 20.36}{3.25 - 15.90} = 3.25 \text{ m/s}
$$

$$
t_{\text{mid}} = 3.25 \text{ m/s}^2
$$

$$
t_{\text{mid}} = 4.25 \text{ m/s}^2
$$

$$
t_{\text{mid}} = 21.44 \text{ m/s}
$$

$$
t_{\text{mid}} = 2.50 \text{ m/s}
$$

$$
t_{\text{mid}} = 5.32 \text{ m/s}^2
$$

Table of Calculations

.

- 21. By definition, the acceleration is $a = \frac{v v_0}{a} = \frac{25 \text{ m/s} 13 \text{ m/s}}{2.0 \text{ m/s}^2} = 2.0 \text{ m/s}^2$. $25 \text{ m/s} - 13 \text{ m/s}$ $\sqrt{2.0 \text{ m/s}^2}$ $\frac{s-13 \text{ m/s}}{s} = 2.0 \text{ m/s}^2$. 6.0 s $t = 6.0 \text{ s}$ The distance of travel can be found from Eq. 2-11b. $x - x_0 = v_0 t + \frac{1}{2} a t^2 = (13 \text{ m/s})(6.0 \text{ s}) + \frac{1}{2} (2.0 \text{ m/s}^2)(6.0 \text{ s})^2 = 114 \text{ m}$
- 22. The acceleration can be found from Eq. (2-11c).

$$
v^2 = v_0^2 + 2a(x - x_0)
$$
 $\rightarrow a = \frac{v^2 - v_0^2}{2(x - x_0)} = \frac{0 - (23 \text{ m/s})^2}{2(85 \text{ m})} = \boxed{-3.1 \text{ m/s}^2}.$

23. Assume that the plane starts from rest. The runway distance is found by solving Eq. 2-11c for $x - x_0$. $x - x_0$.

$$
v^{2} = v_{0}^{2} + 2a(x - x_{0}) \rightarrow x - x_{0} = \frac{v^{2} - v_{0}^{2}}{2a} = \frac{(33 \text{ m/s})^{2} - 0}{2(3.0 \text{ m/s}^{2})} = 1.8 \times 10^{2} \text{ m}
$$

24. The sprinter starts from rest. The average acceleration is found from Eq. 2-11c.

$$
v^2 = v_0^2 + 2a(x - x_0)
$$
 $\rightarrow a = \frac{v^2 - v_0^2}{2(x - x_0)} = \frac{(11.5 \text{ m/s})^2 - 0}{2(15.0 \text{ m})} = 4.408 \text{ m/s}^2 \approx 4.41 \text{ m/s}^2$.

. The elapsed time is found by solving Eq. 2-11a for time.

$$
v = v_0 + at
$$
 \rightarrow $t = \frac{v - v_0}{a} = \frac{11.5 \text{ m/s} - 0}{4.408 \text{ m/s}^2} = 2.61 \text{ s}$

25. The words "slowing down uniformly" implies that the car has a constant acceleration. The distance of travel is found form combining Eqs. 2-7 and 2-8.
 $y = \frac{v_0 + v_1}{(21.0 \text{ m/s} + 0 \text{ m/s})}$ (6.00.000) = 63.0 m

$$
x - x_0 = \frac{v_0 + v}{2}t = \left(\frac{21.0 \text{ m/s} + 0 \text{ m/s}}{2}\right)(6.00 \text{ sec}) = \boxed{63.0 \text{ m}}.
$$

26. The final velocity of the car is zero. The initial velocity is found from Eq. 2-11c with $v = 0$ and solving for v_0 . v_0 .

$$
v^{2} = v_{0}^{2} + 2a(x - x_{0}) \rightarrow v_{0} = \sqrt{v^{2} - 2a(x - x_{0})} = \sqrt{0 - 2(-7.00 \text{ m/s}^{2})(92 \text{ m})} = 36 \text{ m/s}
$$

27. The final velocity of the driver is zero. The acceleration is found from Eq. 2-11c with $v = 0$ and solving for *a* .

$$
a = \frac{v^2 - v_0^2}{2(x - x_0)} = \frac{0 - \left[(85 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) \right]^2}{2(0.80 \text{ m})} = -348.4 \text{ m/s}^2 \approx \boxed{-3.5 \times 10^2 \text{ m/s}^2}
$$

Converting to "g's":
$$
a = \frac{-3.484 \times 10^2 \text{ m/s}^2}{(9.8 \text{ m/s}^2)/g} = \boxed{-36 g\text{'s}}.
$$

28. The origin is the location of the car at the beginning of the reaction time. The initial speed of the car is $(95 \text{ km/h})\left(\frac{1 \text{ m/s}}{1.1 \text{ m/s}}\right)$ = 26.39 m/s. The location where the brakes are applied is found from 3.6 km/h $\frac{1}{2}$. The location where the brakes are applied is found from

the equation for motion at constant velocity: $x_0 = v_0 t_R = (26.39 \text{ m/s})(1.0 \text{ s}) = 26.39 \text{ m}$. This is $26.39 \,\mathrm{m/s}$ $(1.0 \,\mathrm{s}) = 26.39 \,\mathrm{m}$. This is now the starting location for the application of the brakes. In each case, the final speed is 0. (*a*) Solve Eq. 2-11c for the final location.

$$
v^2 = v_0^2 + 2a(x - x_0)
$$
 $\rightarrow x = x_0 + \frac{v^2 - v_0^2}{2a} = 26.39 \text{ m} + \frac{0 - (26.39 \text{ m/s})^2}{2(-4.0 \text{ m/s}^2)} = 113 \text{ m}$

(*b*) Solve Eq. 2-11c for the final location with the second acceleration.

$$
x = x_0 + \frac{v^2 - v_0^2}{2a} = 26.39 \text{ m} + \frac{0 - (26.39 \text{ m/s})^2}{2(-8.0 \text{ m/s}^2)} = 70 \text{ m}
$$

29. The origin is the location of the car at the beginning of the reaction time. The location where the brakes are applied is found from the equation for motion at constant velocity: $x_0 = v_0 t_R$ $x_0 = v_0 t_R$ This is the starting location for the application of the brakes. Solve Eq. 2-11c for the final location of the car, with $v = 0$.

$$
x = x_0 + \frac{v^2 - v_0^2}{2a} = v_0 t_R - \frac{v_0^2}{2a}
$$

30. The critical condition is that the total distance covered by the passing car and the approaching car must be less than 400 m so that they do not collide. The passing car has a total displacement composed of several individual parts. These are: i) the 10 m of clear room at the rear of the truck, ii) the 20 m length of the truck, iii) the 10 m of clear room at the front of the truck, and iv) the distance the truck travels. Since the truck travels at a speed of $\bar{v} = 25 \text{ m/s}$, the truck will have a displacement of Δx _{truck} = $(25 \text{ m/s})t$. Thus the total displacement of the car during passing is Δx _{passing} = 40 m + (25 m/s)t. $x_{\text{passing}} = 40 \text{ m} + (25 \text{ m/s}) t.$

To express the motion of the car, we choose the origin to be at the location of the passing car when the decision to pass is made. For the passing car, we have an initial velocity of $v_0 = 25 \text{ m/s}$ and an $v_0 = 25 \text{ m/s}$ and an acceleration of $a = 1.0 \text{ m/s}^2$. Find $\Delta x_{\text{passing}}$ from Eq. 2-11b.

$$
\Delta x_{\text{passing}} = x_c - x_0 = v_0 t + \frac{1}{2} a t = (25 \text{ m/s}) t + \frac{1}{2} (1.0 \text{ m/s}^2) t^2
$$

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Set the two expressions for Δx s Δx equal to each other in order to find the time required to pass.

$$
40 \text{ m} + (25 \text{ m/s}) t_{\text{pass}} = (25 \text{ m/s}) t_{\text{pass}} + \frac{1}{2} (1.0 \text{ m/s}^2) t_{\text{pass}}^2 \rightarrow 40 \text{ m} = \frac{1}{2} (1.0 \text{ m/s}^2) t_{\text{pass}}^2 \rightarrow t_{\text{pass}} = \sqrt{80 \text{s}^2} = 8.94 \text{ s}
$$

Calculate the displacements of the two cars during this time.

$$
\Delta x_{\text{passing}} = 40 \,\text{m} + (25 \,\text{m/s})(8.94 \,\text{s}) = 264 \,\text{m}
$$
\n
$$
\Delta x_{\text{approxning}} = v_{\text{approxening}}t = (25 \,\text{m/s})(8.94 \,\text{s}) = 224 \,\text{m}
$$

Thus the two cars together have covered a total distance of 488 m, which is more than allowed.

The car should not pass.

31. During the final part of the race, the runner must have a displacement of 1100 m in a time of 180 s (3 min). Assume that the starting speed for the final part is the same as the average speed thus far.

Average speed =
$$
\frac{d}{\Delta t} = \frac{8900 \text{ m}}{(27 \times 60) \text{ s}} = 5.494 \text{ m/s} = v_0
$$

The runner will accomplish this by accelerating from speed v_0 to speed v for t seconds, covering a distance d_1 , and then running at a constant speed of *v* for $(180-t)$ seconds, covering a distance d_2 .
We have these relationships:

$$
v = v_o + at \t d_1 = v_o t + \frac{1}{2}at^2 \t d_2 = v(180 - t) = (v_o + at)(180 - t)
$$

1100 m = d₁ + d₂ = v_ot + $\frac{1}{2}$ at² + (v₀ + at)(180 - t) \rightarrow 1100 m = 180v₀ + 180at - $\frac{1}{2}$ at² \rightarrow
1100 m = (180 s)(5.494 m/s) + (180 s)(0.2 m/s²)t - $\frac{1}{2}$ (0.2 m/s²)t²
0.1t² - 36t + 111 = 0 \t t = 357 s, 3.11 s

 $t^2 - 36t + 111 = 0$ $t = 357$ s, 3.11 s

Since we must have $t < 180$ s, the solution is $t = 3.1$ s.

$$
\boxed{32.} \text{ The car's initial speed is } v_o = (45 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) = 12.5 \text{ m/s} \ .
$$

Case I: trying to stop. The constraint is, with the braking deceleration of the car $(a = -5.8 \text{ m/s}^2)$, Case I: trying to stop. The constraint is, with the braking deceleration of the car $(a = -5.8 \text{ m/s}^2)$, can the car stop in a 28 m displacement? The 2.0 seconds has no relation to this part of the problem.

Using equation (2-11c), the distance traveled during braking is

$$
(x - x_0) = \frac{v^2 - v_0^2}{2a} = \frac{0 - (12.5 \text{ m/s})^2}{2(-5.8 \text{ m/s}^2)} = 13.5 \text{ m}
$$
 [She can stop the car in time.]

Case II: crossing the intersection. The constraint is, with the acceleration of the car

$$
a = \left(\frac{65 \text{ km/h} - 45 \text{ km/h}}{6.0 \text{ s}}\right) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}}\right) = 0.9259 \text{ m/s}^2
$$
, can she get through the intersection

(travel 43 meters) in the 2.0 seconds before the light turns red? Using equation (2.11b), the distance traveled during the 2.0 sec is

$$
(x - x_0) = v_0 t + \frac{1}{2} a t^2 = (12.5 \text{ m/s})(2.0 \text{ s}) + \frac{1}{2} (0.927 \text{ m/s}^2)(2.0 \text{ s})^2 = 26.9 \text{ m}.
$$

She should stop.

33. Choose downward to be the positive direction, and take $y_0 = 0$ at the top of the cliff. The initial velocity is $v_0 = 0$, and the acceleration is $a = 9.80 \text{ m/s}^2$. The displacement is found from equation (2-11b), with *x* replaced by *y*.

$$
y = y_0 + v_0 t + \frac{1}{2} a t^2 \rightarrow y - 0 = 0 + \frac{1}{2} (9.80 \text{ m/s}^2) (3.25 \text{ s})^2 \rightarrow y = 51.8 \text{ m}
$$

34. Choose downward to be the positive direction. The initial velocity is $v_0 = 0$, the final velocity is

$$
v = (85 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) = 23.61 \text{ m/s}
$$
, and the acceleration is $a = 9.80 \text{ m/s}^2$. The time can be

found by solving Eq. 2-11a for the time.

$$
v = v_0 + at
$$
 \rightarrow $t = \frac{v - v_0}{a} = \frac{23.61 \text{ m/s} - 0}{9.80 \text{ m/s}^2} = 2.4 \text{ s}$

- 35. Choose downward to be the positive direction, and take $y_0 = 0$ to be at the top of the Empire State Building. The initial velocity is $v_0 = 0$, and the acceleration is $a = 9.80 \text{ m/s}^2$. *a* Building. The initial velocity is $v_0 = 0$, and the acceleration is $a = 9.80 \text{ m/s}^2$.
(*a*) The elapsed time can be found from Eq. 2-11b, with *x* replaced by *y*.
	-

$$
y - y_0 = v_0 t + \frac{1}{2} a t^2
$$
 \rightarrow $t = \sqrt{\frac{2y}{a}} = \sqrt{\frac{2(380 \text{ m})}{9.80 \text{ m/s}^2}} = 8.806 \text{ s} \approx 8.8 \text{ s}.$

(*b*) The final velocity can be found from equation (2-11a). $2\left(0.906 \text{ s}\right)$ 96 m/s $v = v_0 + at = 0 + (9.80 \text{ m/s}^2)(8.806 \text{ s}) = |86 \text{ m/s}|$

36. Choose upward to be the positive direction, and take $y_0 = 0$ to be at the height where the ball was hit. For the upward path, $v_0 = 22 \text{ m/s}$, $v = 0$ at the top of the path, and $a = -9.80 \text{ m/s}^2$. $a = -9.80 \,\mathrm{m/s^2}$.

(*a*) The displacement can be found from Eq. 2-11c, with *x* replaced by *y* .

$$
v^2 = v_0^2 + 2a(y - y_0)
$$
 $\rightarrow y = y_0 + \frac{v^2 - v_0^2}{2a} = 0 + \frac{0 - (22 \text{ m/s})^2}{2(-9.80 \text{ m/s}^2)} = 25 \text{ m}$

(*b*) The time of flight can be found from Eq. 2-11b, with *x* replaced by *y* , using a displacement of 0 for the displacement of the ball returning to the height from which it was hit.

$$
y = y_0 + v_0 t + \frac{1}{2} a t^2 = 0 \quad \rightarrow \quad t \left(v_0 + \frac{1}{2} a t \right) = 0 \quad \rightarrow \quad t = 0 \text{ , } t = \frac{2v_0}{-a} = \frac{2(22 \text{ m/s})}{-9.80 \text{ m/s}^2} = 4.5 \text{ s}
$$

The result of $t = 0$ s is the time for the original displacement of zero (when the ball was hit), and the result of $t = 4.5$ s is the time to return to the original displacement. Thus the answer is $t = 4.5$ seconds.

37. Choose upward to be the positive direction, and take $y_0 = 0$ to be the height from which the ball was thrown. The acceleration is $a = -9.80 \text{ m/s}^2$. The displacement upon catching the ball is 0, assuming it was caught at the same height from which it was thrown. The starting speed can be found from Eq. 2-11b, with *x* replaced by *y*.

$$
y = y_0 + v_0 t + \frac{1}{2} a t^2 = 0 \rightarrow
$$

$$
v_0 = \frac{y - y_0 - \frac{1}{2} a t^2}{t} = -\frac{1}{2} a t = -\frac{1}{2} (-9.80 \text{ m/s}^2) (3.0 \text{ s}) = 14.7 \text{ m/s} \approx \boxed{15 \text{ m/s}}
$$

The height can be calculated from Eq. 2-11c, with a final velocity of $v = 0$ at the top of the path.

$$
v^{2} = v_{0}^{2} + 2a(y - y_{0}) \rightarrow y = y_{0} + \frac{v^{2} - v_{0}^{2}}{2a} = 0 + \frac{0 - (14.7 \text{ m/s})^{2}}{2(-9.8 \text{ m/s}^{2})} = 11 \text{ m}
$$

38. Choose downward to be the positive direction, and take $y_0 = 0$ to be at the height where the object was released. The initial velocity is $v_0 = 0$, and the acceleration is $a = 9.80 \text{ m/s}^2$.

- was released. The initial velocity is $v_0 = 0$, and the acceleration is $a = 9.80 \text{ m/s}^2$.

(*a*) The speed of the object will be given by Eq. 2-11a with $v_0 = 0$, and so $v = at = (9.80 \text{ m/s}^2)t$. The speed of the object will be given by Eq. 2-11a with $v_0 = 0$, and so $v = at = (9.80 \text{ m/s}^2)t$.
This is the equation of a straight line passing through the origin with a slope of 9.80 m/s^2 . $9.80 \,\mathrm{m/s^2}$.
- (*b*) The distance fallen will be given by equation (2-11b) with $v_0 = 0$, and so The distance fallen will be given by equation (2-11b) with $v_0 = 0$, and so $y = y_0 + v_0 t + \frac{1}{2} a t^2 = 0 + 0 + (4.90 \text{ m/s}^2) t^2$. This is the equation of a parabola, centered on the t-axis, opening upward.

39. Choose downward to be the positive direction, and take $y_0 = 0$ to be the height where the object was released. The initial velocity is $v_0 = -5.20 \text{ m/s}^2$, the acceleration is $a = 9.80 \text{ m/s}^2$, and the $a = 9.80 \,\mathrm{m/s^2}$, and the displacement of the package will be $y = 125$ m. The time to reach the ground can be found from Eq. 2-11b, with *x* replaced by *y*.

$$
y = y_0 + v_0 t + \frac{1}{2} a t^2 \quad \rightarrow \quad t^2 + \frac{2v_0}{a} t - \frac{2y}{a} = 0 \quad \rightarrow \quad t^2 + \frac{2(-5.2 \text{ m/s})}{9.80 \text{ m/s}^2} t - \frac{2(125 \text{ m})}{9.80 \text{ m/s}^2} = 0 \quad \rightarrow
$$

\n $t = 5.61 \text{ s}, \quad -4.55 \text{ s}$
\nThe correct time is the positive answer, $t = 5.61 \text{ s}$.

40. Choose downward to be the positive direction, and take $y_0 = 0$ to be the height from which the object is released. The initial velocity is $v_0 = 0$, the acceleration is $a = g$. Then we can calculate the position as a function of time from Eq. 2-11b, with *x* replaced by *y*, as $y(t) = \frac{1}{2}gt^2$. At the end $2 \delta^{\prime}$. The theorem of each second, the position would be as follows:2 ²

 $y(0) = 0$; $y(1) = \frac{1}{2}g$; $y(2) = \frac{1}{2}g(2)^2 = 4y(1)$; $y(3) = \frac{1}{2}g(3)^2 = 9y(1)$

The distance traveled during each second can be found by subtracting two adjacent position values from the above list.

$$
d(1) = y(1) - y(0) = y(1); \quad d(2) = y(2) - y(1) = 3y(1); \quad d(3) = y(3) - y(2) = 5y(1)
$$

We could do this in general.

$$
y(n) = \frac{1}{2}gn^{2} \qquad y(n+1) = \frac{1}{2}g(n+1)^{2}
$$

\n
$$
d(n+1) = y(n+1) - y(n) = \frac{1}{2}g(n+1)^{2} - \frac{1}{2}gn^{2} = \frac{1}{2}g((n+1)^{2} - n^{2})
$$

\n
$$
= \frac{1}{2}g(n^{2} + 2n + 1 - n^{2}) = \frac{1}{2}g(2n+1)
$$

The value of $(2n+1)$ is always odd, in the sequence $\vert 1, 3, 5, 7, \ldots \vert$

41. Choose upward to be the positive direction, and take $y_0 = 0$ to be the height from which the ball is thrown. The initial velocity is v_0 , the acceleration is $a = -g$, and the final location for the round trip is $y = 0$. The velocity under those conditions can be found from Eq. 2-11c, with *x* replaced by *y*.

$$
v^2 - v_0^2 = 2ay = 0
$$
 \rightarrow $v^2 = v_0^2$ \rightarrow $v = \pm v_0$

The two results represent two different velocities for the same displacement of 0. The positive sign $(v = v_0)$ is the initial velocity, when the ball is moving upwards, and the negative sign $(v = -v_0)$ is $v = -v_0$) is the final velocity, when the ball is moving downwards. Both of these velocities have the same magnitude, and so the ball has the same speed at the end of its flight as at the beginning.

- 42. Choose upward to be the positive direction, and $y_0 = 0$ to be the height from which the stone is thrown. We have $v_0 = 18.0 \text{ m/s}$, $a = -9.80 \text{ m/s}^2$, and $y - y_0 = 11.0 \text{ m}$. $a = -9.80 \text{ m/s}^2$, and $y - y_0 = 11.0 \text{ m}$. $y - y_0 = 11.0 \text{ m}.$
	- (*a*) The velocity can be found from Eq, 2-11c, with *x* replaced by *y*.

$$
v^{2} = v_{0}^{2} + 2a(y - y_{0}) = 0 \rightarrow
$$

$$
v = \pm \sqrt{v_{0}^{2} + 2ay} = \pm \sqrt{(18.0 \text{ m/s})^{2} + 2(-9.80 \text{ m/s}^{2})(11.0 \text{ m})} = \pm 10.4 \text{ m/s}
$$

Thus the speed is $\left|v\right| = 10.4 \,\mathrm{m/s}$

(*b*) The time to reach that height can be found from equation (2-11b).

$$
y = y_0 + v_0 t + \frac{1}{2} a t^2 \rightarrow t^2 + \frac{2(18.0 \text{ m/s})}{-9.80 \text{ m/s}^2} t + \frac{2(-11.0 \text{ m})}{-9.80 \text{ m/s}^2} = 0 \rightarrow t^2 - 3.673t + 2.245 = 0 \rightarrow t = 2.90 \text{ s}, 0.775 \text{ s}
$$

- (*c*) There are two times at which the object reaches that height once on the way up $(t = 0.775 \text{ s})$, and once on the way down $(t = 2.90 \text{ s})$.
- 43. The 10-cm (100 mm) apple has a diameter of about 6 mm as measured in the photograph. Thus any distances measured from the picture need to be multiplied by 100 / 6. Choose the downward direction to be positive. Choose $y_0 = 0$ to be stem of the apple on the THIRD image from the top of the picture. It is the first picture in which the stem of the apple is visible. The velocity of the apple at that position is not 0, but it is not known either. Call it v_0 . We will choose that the time at that point is $t = 0$, and we call the time interval from one picture to the next to be T . The acceleration of the apple is $a = g = 9.8 \text{ m/s}^2$. $a = g = 9.8 \,\mathrm{m/s}^2$.

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The 3rd picture after the $t = 0$ picture (the first one that is not overlapping with another image) has the stem 16.5 mm from the origin of coordinates, at a time of $t = 3T$. The actual position would be found by
 $y_1 = (16.5 \text{ mm})(100/6) = 275 \text{ mm} = 0.275 \text{ m}.$

 $y_1 = (16.5 \text{ mm})(100/6) = 275 \text{ mm} = 0.275 \text{ m}.$

The 6th picture after the $t = 0$ picture (the next to last one in the picture) has the stem 42 mm from the origin of coordinates, at a time of $t = 6T$. The actual position would be found by

 $y_2 = (42 \text{ mm})(100/6) = 700 \text{ mm} = 0.70 \text{ m}.$

Now we have two sets of position-time data, relative to the origin. Both of those sets of positiontime data must satisfy equation Eq. 2-11b.

$$
y_1 = y_0 + v_0 t_1 + \frac{1}{2} a t_1^2 \rightarrow 0.275 = 3v_0 T + \frac{1}{2} g (3T)^2
$$

\n
$$
y_2 = y_0 + v_0 t_2 + \frac{1}{2} a t_2^2 \rightarrow 0.70 = 6v_0 T + \frac{1}{2} g (6T)^2
$$

Multiply the first equation by 2, and then subtract it from the second equation to eliminate the dependence on v_0 . The resulting equation can be solved for T .

$$
0.55 \text{ m} = 6v_0 T + 9gT^2
$$

0.70 m = $6v_0 T + 18gT^2$ \rightarrow 0.15 m = $9gT^2$ \rightarrow $T = \sqrt{\frac{0.15 \text{ m}}{9(9.8 \text{ m/s}^2)}}$ = $\frac{4.1 \times 10^{-2} \text{s}}{4.1 \times 10^{-2} \text{s}}$
This is equivalent to $\frac{1 \text{ flash}}{T} = \frac{1 \text{ flash}}{4.1 \times 10^{-2} \text{s}}$ = 24 flashes per second.

44. Choose downward to be the positive direction, and $y_0 = 0$ to be the height from which the stone is dropped. Call the location of the top of the window y_w , and the time for the stone to fall from release to the top of the window is t_{w} . Since the stone is dropped from rest, using Eq. 2-11b with *y* substituting for *x*, we have $y_w = y_0 + v_0 t + \frac{1}{2} a t^2 = 0 + 0 + \frac{1}{2} g t_w^2$. The location of the bottom of the window is $y_w + 2.2$ m, and the time for the stone to fall from release to the bottom of the window is t_{w} +0.28 s. Since the stone is dropped from rest, using Eq. 2-11b, we have t_w + 0.28 s. Since the stone is dropped from rest, using Eq. 2-11b, we have
 y_w + 2.2 m = y_0 + v_0 + $\frac{1}{2}at^2$ = 0 + 0 + $\frac{1}{2}g(t_w$ + 0.28 s)². Substituting the first expression for y_w into y_w into

the second one. $\frac{1}{2}gt_w^2 + 2.2 \text{ m} = \frac{1}{2}g(t_w + 0.28 \text{ s})^2 \rightarrow t_w = 0.662 \text{ s}$

Use this time in the first equation.

 $y_w = \frac{1}{2}gt_w^2 = \frac{1}{2}(9.8 \text{ m/s}^2)(0.662 \text{ s})^2 = 2.1 \text{ m}.$ $9.8 \,\mathrm{m/s^2}$ $(0.662 \,\mathrm{s})^2 = 2.1 \,\mathrm{m}$.

45. For the falling rock, choose downward to be the positive direction, and $y_0 = 0$ to be the height from which the stone is dropped. The initial velocity is $v_0 = 0$ m/s, the acceleration is $a = g$, the displacement is $y = H$, and the time of fall is t_1 . Using Eq. 2-11b with *y* substituting for *x*, we have $H = y_0 + v_0 t + \frac{1}{2} t^2 = 0 + 0 + \frac{1}{2} g t_1^2$.

For the sound wave, use the constant speed equation that $v_s = \frac{d}{\Delta t} = \frac{H}{T - t_1}$, which can be rearranged t $T-t_1$, which can be rearranged

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

to give $t_1 = T - \frac{H}{v_s}$, where $T = 3.2$ s is the total time elapsed from dropping the rock to hearing the $v_{\rm s}$ and $v_{\rm s}$ are $v_{\rm s}$ and , where $T = 3.2$ s is the total time elapsed from dropping the rock to hearing the

sound. Insert this expression for t_1 into the equation for *H*, and solve for *H*.

$$
H = \frac{1}{2}g\left(T - \frac{H}{v_s}\right)^2 \rightarrow \frac{g}{2v_s^2}H^2 - \left(\frac{gT}{v_s} + 1\right)H + \frac{1}{2}gT^2 = 0 \rightarrow
$$

4.239×10⁻⁵ H² - 1.092H + 50.18 = 0 \rightarrow H = 46.0 m, 2.57×10⁴ m
If the larger answer is used in $t_1 = T - \frac{H}{v_s}$, a negative time of fall results, and so the physically

correct answer is $H = 46$ m.

46. Choose upward to be the positive direction, and $y_0 = 0$ to be the location of the nozzle. The initial velocity is v_0 , the acceleration is $a = -9.8 \text{ m/s}^2$, the final location is $y = -1.5 \text{ m}$, and the time of flight is $t = 2.0$ s. Using Eq. 2-11b and substituting *y* for *x* gives the following.

$$
y = y_0 + v_0 t + \frac{1}{2} a t^2 \quad \rightarrow \quad v_0 = \frac{y - \frac{1}{2} a t^2}{t} = \frac{-1.5 \text{ m} - \frac{1}{2} \left(-9.8 \text{ m/s}^2\right) \left(2.0 \text{ s}\right)^2}{2.0 \text{ s}} = \boxed{9.1 \text{ m/s}}
$$

- 47. Choose downward to be the positive direction, and $y_0 = 0$ to be at the top of the cliff. The initial velocity is $v_0 = -12.0 \text{ m/s}$, the acceleration is $a = 9.80 \text{ m/s}^2$, and the final location is $y = 70.0 \text{ m}$.
	- velocity is $v_0 = -12.0 \text{ m/s}$, the acceleration is $a = 9.80 \text{ m/s}^2$, and the final location is $y = 70.0 \text{ m}$.
(*a*) Using Eq. 2-11b and substituting *y* for *x*, we have $v = v_0 + v_1 t + \frac{1}{2} a t^2$ $\rightarrow (4.9 \text{ m/s}^2) t^2$ (12 $y = y_0 + v_0 t + \frac{1}{2} a t^2 \rightarrow (4.9 \text{ m/s}^2) t^2 - (12.0 \text{ m/s}) t - 70 \text{ m} = 0 \rightarrow t = -2.749 \text{ s}, 5.198 \text{ s}.$ $y = y_0 + v_0 t + \frac{1}{2} a t^2 \rightarrow (4.9 \text{ m/s}^2) t^2 - (12.0 \text{ m/s}) t - 70 \text{ m} = 0 \rightarrow t = -2.749 \text{ s}, 5.198 \text{ s}.$
The positive answer is the physical answer: $\boxed{t = 5.20 \text{ s}}$.

- (*b*) Using Eq. 2-11a, we have $v = v_0 + at = -12.0 \text{ m/s} + (9.80 \text{ m/s}^2)(5.198 \text{ s}) = |38.9 \text{ m/s}|.$
- (*c*) The total distance traveled will be the distance up plus the distance down. The distance down will be 70 m more than the distance up. To find the distance up, use the fact that the speed at the top of the path will be 0. Then using Eq. 2-11c: 2 ² ²

$$
v^2 = v_0^2 + 2a(y - y_0)
$$
 $\rightarrow y = y_0 + \frac{v^2 - v_0^2}{2a} = 0 + \frac{0 - (-12.0 \text{ m/s})^2}{2(9.80 \text{ m/s}^2)} = -7.35 \text{ m}.$

Thus the distance up is 7.35 m, the distance down is 77.35 m, and the total distance traveled is 84.7 m .

- 48. Choose upward to be the positive direction, and $y_0 = 0$ to be the level from which the ball was thrown. The initial velocity is v_0 , the instantaneous velocity is $v = 13 \text{ m/s}$, the acceleration is itial velocity is v_0 , the instantaneous velocity is $v = 13 \text{ m/s}$, the acceleration is v_0 and the location of the window is $v_0 = 29 \text{ m}$. *a* = -9.80 m/s², and the location of the window is $y = 28$ m.
(*a*) Using Eq. 2-11c and substituting *y* for *x*, we have
	-

$$
v^{2} = v_{0}^{2} + 2a(y - y_{0}) \rightarrow
$$

\n
$$
v_{0} = \pm \sqrt{v^{2} - 2a(y - y_{0})} = \pm \sqrt{(13 \text{ m/s})^{2} - 2(-9.8 \text{ m/s}^{2})(28 \text{ m})} = \boxed{27 \text{ m/s}}
$$

Choose the positive value because the initial direction is upward.

- - (*b*) At the top of its path, the velocity will be 0, and so we can use the initial velocity as found above, along with Eq. 2-11c.

$$
v^{2} = v_{0}^{2} + 2a(y - y_{0}) \rightarrow y = y_{0} + \frac{v^{2} - v_{0}^{2}}{2a} = 0 + \frac{0 - (27 \text{ m/s})^{2}}{2(-9.8 \text{ m/s}^{2})} = 1.37 \text{ m}
$$

(*c*) We want the time elapsed from throwing (speed $v_0 = 27 \text{ m/s}$) to reaching the window (speed *v* = 13 m/s). Using Eq. 2-11a, we have:
 $v = v_0 + st$, $t = \frac{v - v_0}{v} = \frac{13 \text{ m/s} - 27 \text{ m/s}}{14 \text{ s}}$

$$
v = v_0 + at
$$
 \rightarrow $t = \frac{v - v_0}{a} = \frac{13 \text{ m/s} - 27 \text{ m/s}}{-9.80 \text{ m/s}^2} = 1.4 \text{ s}.$

(*d*) We want the time elapsed from the window (speed $v_0 = 13 \text{ m/s}$) to reaching the street (speed $v = -27$ m/s). Using Eq. 2-11a, we have: $27 \text{ m/s} - 13 \text{ m/s}$ $v - v_0$ –27 m/s –13 m/s . A construction of the construction of th

$$
v = v_0 + at
$$
 \rightarrow $t = \frac{v - v_0}{a} = \frac{-27 \text{ m/s} - 13 \text{ m/s}}{-9.80 \text{ m/s}^2} = 4.1 \text{ s}.$

- 49. Slightly different answers may be obtained since the data comes from reading the graph.
	- (*a*) The greatest velocity is found at the highest point on the graph, which is at $t \approx 48$ s.
	- (*b*) The indication of a constant velocity on a velocity-time graph is a slope of 0, which occurs from $t = 90 \text{ s}$ to $t \approx 108 \text{ s}$.
	- (*c*) The indication of a constant acceleration on a velocity-time graph is a constant slope, which occurs from $t = 0$ s to $t \approx 38$ s, again from $t \approx 65$ s to $t \approx 83$ s, and again from $t = 90 \text{ s}$ to $t \approx 108 \text{ s}$.
	- (*d*) The magnitude of the acceleration is greatest when the magnitude of the slope is greatest, which occurs from $t \approx 65$ s to $t \approx 83$ s.
- 50. Slightly different answers may be obtained since the data comes from reading the graph.
	- (*a*) The instantaneous velocity is given by the slope of the tangent line to the curve. At $t = 10.0$ s, the slope is approximately $v(10) \approx \frac{3 \text{ m} 0}{\sqrt{300}} = 0.3 \text{ m/s}$. $10 \approx \frac{3 \text{ m/s}}{100 \text{ s}} = |0.3 \text{ m/s}|.$ $10.0 s - 0$ the slope is approximately $v(10) \approx \frac{3 \text{ m} - 0}{10.0 \text{ s} - 0} = \boxed{0.3 \text{ m/s}}$.

(*b*) At $t = 30.0$ s, the slope of the tangent line to the curve, and thus the instantaneous velocity, is approximately $v(30) \approx \frac{22 \text{ m} - 8 \text{ m}}{24 \text{ m/s}} = 1.4 \text{ m/s}.$ $30 \approx \frac{22 \text{ m}}{1.4 \text{ m/s}} = |1.4 \text{ m/s}|.$ $35 s - 25 s$ (*c*) The average velocity is given by $\overline{v} = \frac{x(5) \text{ m} - x(0) \text{ m}}{2} = \frac{1.5 \text{ m} - 0}{2} = .30 \text{ m/s}.$ $.30 \,\mathrm{m/s}$. $5.0 s - 0 s$ $5.0 s$ (*d*) The average velocity is given by $\bar{v} = \frac{x(30) \text{ m} - x(25) \text{ m}}{24.3 \text{ m}^2} = \frac{16 \text{ m} - 9 \text{ m}}{24.4 \text{ m/s}} = 1.4 \text{ m/s}$. 1.4 m/s . $30.0 \text{ s} - 25.0 \text{ s}$ 5.0 s \leftarrow 5.0

(e) The average velocity is given by
$$
\overline{v} = \frac{x(50) \text{ m} - x(40) \text{ m}}{50.0 \text{ s} - 40.0 \text{ s}} = \frac{10 \text{ m} - 19.5 \text{ m}}{10.0 \text{ s}} = \boxed{-0.95 \text{ m/s}}.
$$

- 51. Slightly different answers may be obtained since the data comes from reading the graph.
	- (*a*) The indication of a constant velocity on a position-time graph is a constant slope, which occurs from $t = 0$ s to $t \approx 18$ s.
	- (*b*) The greatest velocity will occur when the slope is the highest positive value, which occurs at

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

.

.

 3 m/s^2 .

about $|t = 27$ s.

- (*c*) The indication of a 0 velocity on a position-time graph is a slope of 0, which occurs at about from $t = 38$ s.
- (*d*) The object moves in both directions. When the slope is positive, from $t = 0$ s to $t = 38$ s, the object is moving in the positive direction. When the slope is negative, from $t = 38$ s to $t = 50$ s, the object is moving in the negative direction.
- 52. Slightly different answers may be obtained since the data comes from reading the graph. We assume that the short, nearly horizontal portions of the graph are the times that shifting is occurring, and those times are not counted as being "in" a certain gear.
	- (*a*) The average acceleration in 2nd gear is given by $\overline{a}_2 = \frac{\Delta v_2}{\Delta t} = \frac{24 \text{ m/s}^2 14 \text{ m/s}}{8} = |2.5 \text{ m/s}^2|$. 2 $24 \text{ m/s} - 14 \text{ m/s}$ $\sqrt{25 - 12}$ $2.5 \,\mathrm{m/s^2}$. $8 s - 4 s$ $\overline{a}_2 = \frac{\Delta v_2}{\Delta} = \frac{24 \text{ m/s} - 14 \text{ m/s}}{2.5 \text{ m/s}^2} = 2.5 \text{ m/s}^2$. $t₂$ 8 s-4 s . $44 \text{ m/s} - 37 \text{ m/s}$ $\sqrt{9.64 + 1^2}$

The average acceleration in 4th gear is given by $\overline{a}_4 = \frac{\Delta v_4}{\Delta t_4} = \frac{44 \text{ m/s}^2 - 37 \text{ m/s}}{27 \text{ s} - 16 \text{ s}} = 0.64 \text{ m/s}^2$. $4 \t 27.5 \t 10.5$ $0.64 \,\mathrm{m/s}^2$. $\overline{a}_4 = \frac{\Delta v_4}{v_4} = \frac{44 \text{ m/s} - 37 \text{ m/s}}{4.5 \text{ s}} = \boxed{0.64 \text{ m/s}^2}.$ t_4 27 s - 16 s .

(*b*) The distance traveled can be determined from a velocity-time graph by calculating the area between the graph and the $v = 0$ axis, bounded by the times under consideration. For this case, we will approximate the area as a rectangle.

height =
$$
\overline{v} = \frac{v_f + v_0}{2} = \frac{44 \text{ m/s} + 37 \text{ m/s}}{2} = 40.5 \text{ m/s}
$$
 width = $\Delta t = 27 \text{ s} - 16 \text{ s} = 11 \text{ s}$
Thus the distance traveled is $d = \overline{v} \Delta t = (40.5 \text{ m/s})(11 \text{ s}) = 450 \text{ m}$.

- 53. Slightly different answers may be obtained since the data comes from reading the graph. We assume that the short, nearly horizontal portions of the graph are the times that shifting is occurring, and those times are not counted as being "in" a certain gear.
	- (*a*) The average acceleration in first gear is given by $\bar{a} = \frac{\Delta v}{\Delta t} = \frac{14 \text{ m/s} 0 \text{ m/s}}{4 \text{ m/s}^2} = \sqrt{4 \text{ m/s}^2}$. $\frac{s-0 \text{ m/s}}{s} = 4 \text{ m/s}^2$. $4 s - 0 s$ $t \sim 4 \text{ s}-0 \text{ s}$.

(*b*) The average acceleration in third gear is given by $\bar{a} = \frac{\Delta v}{\Delta t} = \frac{37 \text{ m/s} - 24 \text{ m/s}}{4 \text{ s}^2} = 3 \text{ m/s}^2$. $s - 24 \text{ m/s}$ $\sqrt{2}$ $14 s - 9 s$ $t = 14 \text{ s}-9 \text{ s}$

- (*c*) The average acceleration in fifth gear is given by $\bar{a} = \frac{\Delta v}{\Delta v} = \frac{52 \text{ m/s} 44 \text{ m/s}}{2 \text{ m/s}^2} = \left[0.35 \text{ m/s}^2 \right]$. $s - 44 \text{ m/s}$ $\sqrt{2.25 + 1.21}$ $0.35 \,\mathrm{m/s^2}$. $50 s - 27 s$ $t = 50 s - 27 s$
- (*d*) The average acceleration through the first four gears is given by

$$
\overline{a} = \frac{\Delta v}{\Delta t} = \frac{44 \text{ m/s} - 0 \text{ m/s}}{27 \text{ s} - 0 \text{ s}} = \boxed{1.6 \text{ m/s}^2}.
$$

- 54. Slightly different answers may be obtained since the data comes from reading the graph.
	- (*a*) To estimate the distance the object traveled during the first minute, we need to find the area under the graph, from $t = 0$ s to $t = 60$ s. Each "block" of the graph represents an "area" of $\Delta x = (10 \text{ m/s})(10 \text{ s}) = 100 \text{ m}$. By counting and estimating, there are about 17.5 blocks under the 1st minute of the graph, and so the distance traveled during the 1st minute is about $\left[1750 \text{ m}\right]$.
	- (*b*) For the second minute, there are about 5 blocks under the graph, and so the distance traveled during the second minute is about $[500 \text{ m}]$.

Alternatively, average accelerations can be estimated for various portions of the graph, and then the uniform acceleration equations may be applied. For instance, for part (*a*), break the motion up into

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

two segments, from 0 to 50 seconds and then from 50 to 60 seconds.

$$
t = 0
$$
 to 50: $\overline{a}_1 = \frac{\Delta v}{\Delta t} = \frac{38 \text{ m/s} - 14 \text{ m/s}}{50 \text{ s} - 0 \text{ s}} = 0.48 \text{ m/s}^2$
\n $d_1 = v_{o1}t_1 + \frac{1}{2}\overline{a}_1t_1^2 = (14 \text{ m/s})(50 \text{ s}) + \frac{1}{2}(0.48 \text{ m/s}^2)(50 \text{ s})^2 = 1300 \text{ m}$
\n $\overline{a}_2 = \frac{\Delta v}{\Delta t} = \frac{31 \text{ m/s} - 38 \text{ m/s}}{60 \text{ s} - 50 \text{ s}} = -0.70 \text{ m/s}^2$
\n $d_2 = v_{o2}t_2 + \frac{1}{2}\overline{a}_2t_2^2 = (38 \text{ m/s})(10 \text{ s}) + \frac{1}{2}(-0.70 \text{ m/s}^2)(10 \text{ s})^2 = 345 \text{ m}$
\n $d_1 + d_2 = 1645 \text{ m}$

55. The *v* vs. *t* graph is found by taking the slope of the *x* vs. *t* graph. Both graphs are shown here.

- 56. (*a*) During the interval from A to B, it is \vert moving in the negative direction \vert , because its displacement is negative.
	- (*b*) During the interval from A to B, it is speeding up, because the magnitude of its slope is increasing (changing from less steep to more steep).
	- (*c*) During the interval from A to B, the acceleration is negative, because the graph is concave downward, indicating that the slope is getting more negative, and thus the acceleration is negative.
	- (*d*) During the interval from D to E, it is moving in the positive direction , because the displacement is positive.
	- (*e*) During the interval from D to E, it is $|speeding up|$, because the magnitude of its slope is increasing (changing from less steep to more steep).
	- (*f*) During the interval from D to E, the acceleration is positive, because the graph is concave upward, indicating the slope is getting more positive, and thus the acceleration is positive.
	- (g) During the interval from C to D, the object is not moving in either direction.

The velocity and acceleration are both 0.

57. (*a*) For the free-falling part of the motion, choose downward to be the positive direction, and 0 $y_0 = 0$ to be the height from which the person jumped. The initial velocity is $v_0 = 0$, $y_0 = 0$ to be the height from which the person jumped. The initial velocity is $v_0 = 0$,
acceleration is $a = 9.80 \text{ m/s}^2$, and the location of the net is $y = 15.0 \text{ m}$. Find the speed upon

reaching the net from Eq. (2-11c) with *x* replaced by *y*.
 $\sqrt{2(0.80 \text{ m/s}^2)(15.0 \text{ m})}$ 17.1mls

$$
v^2 = v_0^2 + 2a(y - y_{(1)})
$$
 \rightarrow $v = \pm \sqrt{0 + 2a(y - 0)} = \pm \sqrt{2(9.80 \text{ m/s}^2)(15.0 \text{ m})} = 17.1 \text{ m/s}$

The positive root is selected since the person is moving downward. For the net-stretching part of the motion, choose downward to be the positive direction, and $y_0 = 15.0$ m to be the height at which the person first contacts the net. The initial velocity is $y_0 = 15.0$ m to be the height at which the person first contacts the net. The initial velocity is $v_0 = 17.1$ m/s, the final velocity is $v = 0$, and the location at the stretched position is $v_0 = 17.1 \text{ m/s}$, the final velocity is $v = 0$, and the location at the stretched position is $y = 16.0$ m. Find the acceleration from Eq. (2-11c) with *x* replaced by *y*.

$$
v^{2} = v_{0}^{2} + 2a(y - y_{0}) \rightarrow a = \frac{v^{2} - v_{0}^{2}}{2(y - y_{0})} = \frac{0^{2} - (17.1 \text{ m/s})^{2}}{2(1.0 \text{ m})} = \frac{-150 \text{ m/s}^{2}}{2(1.0 \text{ m})}
$$

- (*b*) For the acceleration to be smaller, in the above equation we see that the displacement would have to be larger. This means that the net should be "loosened".
- 58. Choose the upward direction to be positive, and $y_0 = 0$ to be the level from which the object was thrown. The initial velocity is v_0 and the velocity at the top of the path is $v = 0$ m/s. The height at the top of the path can be found from Eq. (2-11c) with *x* replaced by *y*.

$$
v^{2} = v_{0}^{2} + 2a(y - y_{0}) \rightarrow y - y_{0} = \frac{-v_{0}^{2}}{2a}.
$$

From this we see that the displacement is inversely proportional to the acceleration, and so if the acceleration is reduced by a factor of 6 by going to the Moon, and the initial velocity is unchanged, the displacement increases by a factor of 6 .

59. The initial velocity of the car is $v_0 = (100 \text{ km/h}) \left(\frac{1 \text{ m/s}}{2.6 \text{ km/h}} \right) = 27.8 \text{ m/s}$. Choose $x_0 = 0$ to be $v_0 = (100 \text{ km/h}) \left(\frac{100 \text{ km/h}}{3.6 \text{ km/h}} \right) = 27.8 \text{ m/s}$. Choose $x_0 = 0$ to be $x_0 = 0$ to be

location at which the deceleration begins. We have $v = 0$ m/s and $a = -30g = -294$ m/s². Find $a = -30g = -294 \text{ m/s}^2$. Find the displacement from Eq. (2-11c).

$$
v^{2} = v_{0}^{2} + 2a(x - x_{0}) \rightarrow x = x_{0} + \frac{v^{2} - v_{0}^{2}}{2a} = 0 + \frac{0 - (27.8 \text{ m/s})^{2}}{2(-2.94 \times 10^{2} \text{ m/s}^{2})} = 1.31 \text{ m} \approx 1.3 \text{ m}
$$

60. Choose downward to be the positive direction, and $y_0 = 0$ to be at the height of the bridge. Agent Bond has an initial velocity of $v_0 = 0$, an acceleration of $a = g$, and will have a displacement of $y = 12$ m -1.5 m = 11.5 m. Find the time of fall from Eq. 2-11b with *x* replaced by *y*.

$$
y = y_0 + v_0 t + \frac{1}{2} a t^2 \rightarrow t = \sqrt{\frac{2y}{a}} = \sqrt{\frac{2(11.5 \text{ m})}{9.80 \text{ m/s}^2}} = 1.532 \text{ s}
$$

If the truck is approaching with $v = 25 \text{ m/s}$, then he needs to jump when the truck is a distance away given by $d = vt = (25 \text{ m/s})(1.532 \text{ s}) = 38.30 \text{ m}$. Convert this distance into "poles". $d = (38.30 \text{ m})(1 \text{ pole}/25 \text{ m}) = 1.53 \text{ poles}$

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

So he should jump when the truck is about $|1.5|$ poles away from the bridge.

61. (*a*) Choose downward to be the positive direction, and $y_0 = 0$ to be the level from which the car was dropped. The initial velocity is $v_0 = 0$, the final location is $y = H$, and the acceleration is $a = g$. Find the final velocity from Eq. 2-11c, replacing *x* with *y*.

$$
v^{2} = v_{0}^{2} + 2a(y - y_{0}) \rightarrow v = \pm \sqrt{v_{0}^{2} + 2a(y - y_{0})} = \pm \sqrt{2gH}.
$$

The speed is the magnitude of the velocity, $v = \sqrt{2gH}$.

(*b*) Solving the above equation for the height, we have that $H = \frac{v^2}{\cdot}$. Thus for a collision of $2g$ $H = \frac{1}{x}$. Thus for a collision of *g*

$$
v = (60 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) = 16.67 \text{ m/s}
$$
, the corresponding height is:

$$
H = \frac{v^2}{2g} = \frac{(16.67 \text{ m/s})^2}{2(9.80 \text{ m/s}^2)} = 14.17 \text{ m} \approx \boxed{14 \text{ m}}.
$$

(*c*) For a collision of $v = (100 \text{ km/h}) \left(\frac{1 \text{ m/s}}{100 \text{ km/h}} \right) = 27.78 \text{ m/s}$, the corresponding height is: 3.6 km/h $\frac{1}{2}$ *v* = $(100 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) = 27.78 \text{ m/s}$, the corresponding height is:

2 $(27.78 \text{ m/s})^2$

$$
H = \frac{v^2}{2g} = \frac{(27.78 \text{ m/s})^2}{2(9.80 \text{ m/s}^2)} = 39.37 \text{ m} \approx 39 \text{ m}.
$$

62. The average speed is the distance divided by the time.

$$
\overline{v} = \frac{d}{t} = \left(\frac{1 \times 10^9 \text{ km}}{1 \text{ y}}\right) \left(\frac{1 \text{ y}}{365 \text{ d}}\right) \left(\frac{1 \text{ d}}{24 \text{ h}}\right) = 1.142 \times 10^5 \text{ km/h} \approx \boxed{1 \times 10^5 \text{ km/h}}
$$

63. Use the information for the first 180 m to find the acceleration, and the information for the full motion to find the final velocity. For the first segment, the train has $v_0 = 0$ m/s, $v_1 = 25$ m/s, and a $v_0 = 0 \text{ m/s}$, $v_1 = 25 \text{ m/s}$, and a $v_1 = 25 \text{ m/s}$, and a displacement of $x_1 - x_0 = 180$ m. Find the acceleration from Eq. 2-11c.

$$
v_1^2 = v_0^2 + 2a(x_1 - x_0)
$$
 $\rightarrow a = \frac{v_1^2 - v_0^2}{2(x_1 - x_0)} = \frac{(25 \text{ m/s})^2 - 0}{2(180 \text{ m})} = 1.736 \text{ m/s}^2$

Find the speed of the train after it has traveled the total distance (total displacement of $x_2 - x_0 = 275$ m) using Eq. 2-11c. $x_2 - x_0 = 275$ m) using Eq. 2-11c.

$$
v_2^2 = v_0^2 + 2a(x_2 - x_0) \rightarrow v_2 = \sqrt{v_0^2 + 2a(x_2 - x_0)} = \sqrt{2(1.736 \,\text{m/s}^2)(275 \,\text{m})} = 31 \,\text{m/s}.
$$

64. For the motion in the air, choose downward to be the positive direction, and $y_0 = 0$ to be at the $y_0 = 0$ to be at the height of the diving board. Then diver has $v_0 = 0$, (assuming the diver does not jump upward or downward), $a = g = 9.8 \text{ m/s}^2$, and $y = 4.0 \text{ m}$ when reaching the surface of the water. Find the diver's speed at the water's surface from Eq. 2-11c, with *x* replaced by *y*.

$$
v^{2} = v_{0}^{2} + 2a(y - y_{0})x \rightarrow v = \pm \sqrt{v_{0}^{2} + 2a(y - y_{0})} = \sqrt{0 + 2(9.8 \text{ m/s}^{2})(4.0 \text{ m})} = 8.85 \text{ m/s}
$$

For the motion in the water, again choose down to be positive, but redefine $y_0 = 0$ to be at the $y_0 = 0$ to be at the surface of the water. For this motion, $v_0 = 8.85 \text{ m/s}$, $v = 0$, and $y - y_0 = 2.0 \text{ m}$. Find the $y - y_0 = 2.0$ m. Find the acceleration from Eq. 2-11c, with *x* replaced by *y*.

$$
v^2 = v_0^2 + 2a(y - y_0)
$$
 $\rightarrow a = \frac{v^2 - v_0^2}{2(y - y_0)x} = \frac{0 - (8.85 \text{ m/s})^2}{2(2.0 \text{ m})} = -19.6 \text{ m/s}^2 \approx \boxed{-20 \text{ m/s}^2}$

The negative sign indicates that the acceleration is directed upwards.

65. This problem can be analyzed as a series of three one-dimensional motions: the acceleration phase, the constant speed phase, and the deceleration phase. The maximum speed of the train is:

$$
(90 \text{ km/h})\left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}}\right) = 25 \text{ m/s}.
$$

 $(90 \text{ km/h})\left(\frac{2.44 \text{ m/s}}{3.6 \text{ km/h}}\right) = 25 \text{ m/s}.$
In the acceleration phase, the initial velocity is $v_0 = 0 \text{ m/s}$, the acceleration is $a = 1.1 \text{ m/s}^2$, and the $a = 1.1 \text{ m/s}^2$, and the final velocity is $v = 25 \text{ m/s}$. Find the elapsed time for the acceleration phase from Eq. 2-11a.

$$
v = v_0 + at
$$
 \rightarrow $t_{\text{acc}} = \frac{v - v_0}{a} = \frac{25 \text{ m/s} - 0}{1.1 \text{ m/s}^2} = 22.73 \text{ s}.$

Find the displacement during the acceleration phase from Eq. 2-11b.

$$
(x - x_0)_{\text{acc}} = v_0 t + \frac{1}{2} a t^2 = 0 + \frac{1}{2} (1.1 \text{ m/s}^2) (22.73 \text{ s})^2 = 284 \text{ m}.
$$

In the deceleration phase, the initial velocity is $v_0 = 25 \text{ m/s}$, the acceleration is $a = -2.0 \text{ m/s}^2$, and $a = -2.0 \,\mathrm{m/s}^2$, and the final velocity is $v = 0$ m/s. Find the elapsed time for the deceleration phase from equation Eq. 2-11a.

$$
v = v_0 + at
$$
 \rightarrow $t_{\text{dec}} = \frac{v - v_0}{a} = \frac{0 - 25 \text{ m/s}}{-2.0 \text{ m/s}^2} = 12.5 \text{ s}.$

Find the distance traveled during the deceleration phase from Eq. 2-11b.

$$
(x - x_0)_{\text{dec}} = v_0 t + \frac{1}{2} a t^2 = (25 \text{ m/s})(12.5 \text{ s}) + \frac{1}{2} (-2.0 \text{ m/s}^2)(12.5 \text{ s})^2 = 156 \text{ m}.
$$

The total elapsed time and distance traveled for the acceleration / deceleration phases are:

$$
t_{\text{acc}} + t_{\text{dec}} = 22.7 \text{ s} + 12.5 \text{ s} = 35.2 \text{ s}
$$

$$
(x - x_0)_{\text{acc}} + (x - x_0)_{\text{dec}} = 284 \text{ m} + 156 \text{ m} = 440 \text{ m}
$$

(*a*) If the stations are spaced 1.80 km = 1800 m apart, then there is a total of $\frac{9000 \text{ m}}{1800 \text{ m}} = 5$ inter-5 inter-1800 m inter-

station segments. A train making the entire trip would thus have a total of 5 inter-station segments and 4 stops of 20 s each at the intermediate stations. Since 440 m is traveled during acceleration and deceleration, 1360 m of each segment is traveled at an average speed of $\overline{v} = 25 \text{ m/s}$. The time for that 1360 m is given by

$$
\overline{v} = 25 \text{ m/s}
$$
. The time for that 1360 m is given by
\n
$$
d = \overline{vt} \rightarrow t_{\text{constant}} = \frac{d}{\overline{v}} = \frac{1360 \text{ m}}{25 \text{ m/s}} = 54.4 \text{ s}.
$$
 Thus a total inter-station segment will take 35.2 s

 $+ 54.4$ s = 89.6 s. With 5 inter-station segments of 89.6 s each, and 4 stops of 20 s each, the total time is given by:

$$
t_{0.8 \text{ km}} = 5(89.6 \text{ s}) + 4(20 \text{ s}) = 528 \text{ s} = 8.8 \text{ min}.
$$

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) If the stations are spaced 3.0 km =3000 m apart, then there is a total of $\frac{9000 \text{ m}}{3000 \text{ m}}$ = 3 inter-3 inter-3000 m inter-

station segments. A train making the entire trip would thus have a total of 3 inter-station segments and 2 stops of 20 s each at the intermediate stations. Since 440 m is traveled during acceleration and deceleration, 2560 m of each segment is traveled at an average speed of

 $\overline{v} = 25 \text{ m/s}$. The time for that 2560 m is given by $d = \overline{vt} \rightarrow t = \frac{d}{\overline{v}} = \frac{2560 \text{ m}}{25 \text{ m/s}} = 102.4 \text{ s}$.
Thus a total inter-station segment will take 35.2 s + 102.4 s = 137.6 s. With 3 inter-station 2560 m 100 m 102.4 s $25 \,\mathrm{m/s}$ \overline{v} 25 m/s

segments of 137.6 s each, and 2 stops of 20 s each, the total time is $t_{3.0 \text{ km}} = 3(137.6 \text{ s}) + 2(20 \text{ s}) = 453 \text{ s} = 7.5 \text{ min}$.

$$
t_{3.0\,\mathrm{km}} = 3(137.6\,\mathrm{s}) + 2(20\,\mathrm{s}) = 453\,\mathrm{s} = 7.5\,\mathrm{min}.
$$

66. Choose downward to be the positive direction, and $y_0 = 0$ to be at the start of the pelican's dive. The pelican has an initial velocity is $v_0 = 0$ and an acceleration of $a = g$, and a final location of

 $y = 16.0$ m. Find the total time of the pelican's dive from Eq. 2-11b, with *x* replaced by *y*.

$$
y = y_0 + v_0 t + \frac{1}{2}at^2 \rightarrow y = 0 + 0 + \frac{1}{2}at^2 \rightarrow t_{\text{dive}} = \sqrt{\frac{2y}{a}} = \sqrt{\frac{2(16.0 \text{ m})}{9.80 \text{ m/s}^2}} = 1.81 \text{ s}.
$$

The fish can take evasive action if he sees the pelican at a time of $1.81 \text{ s} - 0.20 \text{ s} = 1.61 \text{ s}$ into the dive. Find the location of the pelican at that time from Eq. 2-11b.

 $^{2}(1.61.8)^{2}$ 12.7 m $y = y_0 + v_0 t + \frac{1}{2}at = 0 + 0 + \frac{1}{2}(9.80 \text{ m/s}^2)(1.61 \text{ s})^2 = 12.7 \text{ m}$

Thus the fish must spot the pelican at a minimum height from the surface of the water of $16.0 \text{ m} - 12.7 \text{ m} = 3.3 \text{ m}$.

67. First consider the "uphill lie", in which the ball is being putted down the hill. Choose $x_0 = 0$ to be $x_0 = 0$ to be the ball's original location, and the direction of the ball's travel as the positive direction. The final velocity of the ball is $v = 0$ m/s, the acceleration of the ball is $a = -2.0$ m/s², and the displacement $a = -2.0 \text{ m/s}^2$, and the displacement of the ball will be $x - x_0 = 6.0$ m for the first case, and $x - x_0 = 8.0$ m for the second case. Find the initial velocity of the ball from Eq. 2-11c.

$$
v^{2} = v_{0}^{2} + 2a(x - x_{0}) \rightarrow v_{0} = \sqrt{v^{2} - 2a(x - x_{0})} = \sqrt{\sqrt{0 - 2(-2.0 \text{ m/s}^{2})(6.0 \text{ m})} = 4.9 \text{ m/s}
$$

$$
\sqrt{0 - 2(-2.0 \text{ m/s}^{2})(8.0 \text{ m})} = 5.7 \text{ m/s}
$$

The range of acceptable velocities for the uphill lie is $\left[4.9 \,\mathrm{m/s} \right]$ to 5.7 m/s, with a spread of 0.8 m/s.

Now consider the "downhill lie", in which the ball is being putted up the hill. Use a very similar set up for the problem, with the basic difference being that the acceleration of the ball is now 2 $a = -3.0 \text{ m/s}^2$. Find the initial velocity of the ball from Eq. 2-11c.

$$
v^{2} = v_{0}^{2} + 2a(x - x_{0}) \rightarrow v_{0} = \sqrt{v^{2} - 2a(x - x_{0})} = \sqrt{0 - 2(-3.0 \text{ m/s}^{2})(6.0 \text{ m})} = 6.0 \text{ m/s}
$$

The range of acceptable velocities for the downhill lie is $\frac{6.0 \text{ m/s to } 6.9 \text{ m/s}}{6.0 \text{ m/s to } 6.9 \text{ m/s}}$, with a spread of 0.9 m/s.

Because the range of acceptable velocities is smaller for putting down the hill, more control in putting is necessary, and so the downhill putt is more difficult.

68. (*a*) The train's constant speed is $v_{\text{train}} = 6.0 \text{ m/s}$, and the location of the empty box car as a function of time is given by $x_{\text{train}} = v_{\text{train}} t = (6.0 \text{ m/s}) t$. The fugitive has $v_0 = 0 \text{ m/s}$ and ime is given by $x_{\text{train}} = v_{\text{train}} t = (6.0 \text{ m/s}) t$. The fugitive has $v_0 = 0 \text{ m/s}$ and
² until his final appeal is 8.0 m/s. The alonged time during appealment in is $a = 4.0 \text{ m/s}^2$ until his final speed is 8.0 m/s. The elapsed time during acceleration is
 $b = \frac{v - v_0}{v} = \frac{8.0 \text{ m/s}}{2.0 \text{ s}} = 2.0 \text{ s}$. Let the origin be the location of the fugitive when he starts to $\frac{1}{2}$ $\frac{8.0 \text{ m/s}}{2}$ = 2.0 s. Let the origin be the location of the fugitive when he starts to $4.0 \,\mathrm{m/s^2}$ $t_{\text{acc}} = \frac{v - v_0}{v} = \frac{8.0 \text{ m/s}}{v} = 2.0 \text{ s}$. Let the origin be the location of the fugitive when he starts to $a = 4.0 \,\mathrm{m/s^2}$ $t_{\text{acc}} = \frac{V_{0}}{a} = \frac{3.6 \text{ m/s}}{4.0 \text{ m/s}^2} = 2.0 \text{ s}$. Let the origin be the location of the fugitive when he starts to run. The first possibility to consider is, "Can the fugitive catch the train before he reaches his

maximum speed?" During the fugitive's acceleration, his location as a function of time is given by $x_{\text{fugitive}} = x_0 + v_0 t + \frac{1}{2} a t^2 = 0 + 0 + \frac{1}{2} (4.0 \text{ m/s}^2) t^2$. For him to catch the train, we must have $x_{\text{fugitive}} = x_0 + v_0 t + \frac{1}{2} a t^2 = 0 + 0 + \frac{1}{2} (4.0 \text{ m/s}^2) t^2$. For him to catch the train, we must have $(6.0 \text{ m/s}) t = \frac{1}{2} (4.0 \text{ m/s}^2) t^2$. The solutions of this are $t = 0$ s. 3.s. Thus $x_{\text{train}} = x_{\text{fugitive}} \rightarrow (6.0 \text{ m/s}) t = \frac{1}{2} (4.0 \text{ m/s}^2) t^2$. The solutions of this are $t = 0 \text{ s}$, 3 s. Thus the fugitive cannot catch the car during his 2.0 s of acceleration.

Now the equation of motion of the fugitive changes. After the 2.0 s acceleration, he runs with a constant speed of 8.0 m/s . Thus his location is now given (for times $t > 2$ s) by the following.

$$
x_{\text{fugitive}} = \frac{1}{2} (4.0 \,\text{m/s}^2) (2.0 \,\text{s})^2 + (8.0 \,\text{m/s}) (t - 2.0 \,\text{s}) = (8.0 \,\text{m/s}) t - 8.0 \,\text{m}.
$$

So now, for the fugitive to catch the train, we again set the locations equal.

$$
x_{\text{train}} = x_{\text{fugitive}} \rightarrow (6.0 \text{ m/s}) t = (8.0 \text{ m/s}) t - 8.0 \text{ m} \rightarrow t = 4.0 \text{ s}
$$

(b) The distance traveled to reach the box car is given by
\n
$$
x_{\text{fugitive}} (t = 4.0 \text{ s}) = (8.0 \text{ m/s})(4.0 \text{ s}) - 8.0 \text{ m} = 24 \text{ m}.
$$

69. Choose downward to be the positive direction, and $y_0 = 0$ to be at the roof from which the stones are dropped. The first stone has an initial velocity of $v_0 = 0$ and an acceleration of $a = g$. Eqs. 2-11a and 2-11b (with *x* replaced by *y*) give the velocity and location, respectively, of the first stone as a function of time.

 $\frac{1}{2}at^2 \rightarrow y - \frac{1}{2}at^2$ $v = v_0 + at \rightarrow v_1 = gt_1$ $y = y_0 + v_0 t + \frac{1}{2}at^2 \rightarrow y_1 = \frac{1}{2}gt_1^2$.

The second stone has the same initial conditions, but its elapsed time $t - 1.50$ s, and so has velocity and location equations as follows.

$$
v_2 = g(t_1 - 1.50 \text{ s})
$$
 $y_2 = \frac{1}{2} g(t_1 - 1.50 \text{ s})^2$

The second stone reaches a speed of $v_2 = 12.0 \text{ m/s}$ at a time given by raches a speed of $v_2 = 12.0 \text{ m/s}$ at a time given by
 $v_2 = 1.50 \text{ s} + \frac{12.0 \text{ m/s}}{s} = 2.72 \text{ s}$

$$
t_1 = 1.50 \text{ s} + \frac{v_2}{g} = 1.50 \text{ s} + \frac{12.0 \text{ m/s}}{9.80 \text{ m/s}^2} = 2.72 \text{ s}.
$$

The location of the first stone at that time is

$$
y_1 = \frac{1}{2}gt_1^2 = \frac{1}{2}(9.80 \text{ m/s}^2)(2.72 \text{ s})^2 = 36.4 \text{ m}.
$$

The location of the second stone at that time is
\n
$$
y_2 = \frac{1}{2}g(t_1 - 1.50 \text{ s})^2 = \frac{1}{2}(9.80 \text{ m/s}^2)(2.72 - 1.50 \text{ s})^2 = 7.35 \text{ m}.
$$

Thus the distance between the two stones is $y_1 - y_2 = 36.4 \text{ m} - 7.35 \text{ m} = 29.0 \text{ m}$. $y_1 - y_2 = 36.4 \text{ m} - 7.35 \text{ m} = 29.0 \text{ m}$.

 v_2 .

70. To find the average speed for the entire race, we must take the total distance divided by the total time. If one lap is a distance of *L* , then the total distance will be 10*L* . The time elapsed at a given constant speed is given by $t = d/v$, so the time for the first 9 laps would be $t_1 = \frac{d}{d} \int v \cdot dV$, and $9L$ $198.0 \,\mathrm{km/h}$ *L* the time for the last lap would be $t_2 = L/v_2$, where v_2 is the average speed for the last lap. Write an

$$
\overline{v} = \frac{d_{\text{total}}}{t_1 + t_2} = \frac{10L}{\frac{9L}{198.0 \text{ km/h}} + \frac{L}{v_2}} = 200.0 \text{ km/h} \rightarrow
$$

$$
v_2 = \frac{1}{10} = \frac{1}{9} = 220.0 \text{ km/h}
$$

$$
\frac{1}{200.0\,\mathrm{km/h}} - \frac{1}{198.0\,\mathrm{km/h}}
$$

71. The initial velocity is $v_0 = (18 \text{ km/h}) \left(\frac{1 \text{ m/s}}{2 \text{ s} \cdot 1 \text{ m/s}} \right) = 5.0 \text{ m/s}$. The final velocity is 3.6 km/h \sim he initial velocity is $v_0 = (18 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) = 5.0 \text{ m/s}$. The final velocity is
 $v_0 = (75 \text{ km/h}) \left(\frac{1 \text{ m/s}}{2.61 \text{ kg}} \right) = 20.83 \text{ m/s}$. The displacement is $x - x_0 = 4.0 \text{ km} = 4000 \text{ m}$. Find the

expression for the average speed for the entire race, and then solve for v_2 .

$$
v_0 = (75 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) = 20.83 \text{ m/s}.
$$
 The displacement is $x - x_0 = 4.0 \text{ km} = 4000 \text{ m}$. Find the

average acceleration from Eq. 2-11c.

$$
v^{2} = v_{0}^{2} + 2a(x - x_{0}) \rightarrow a = \frac{v^{2} - v_{0}^{2}}{2(x - x_{0})} = \frac{(20.83 \text{ m/s})^{2} - (5.0 \text{ m/s})^{2}}{2(4000 \text{ m})} = \boxed{5.1 \times 10^{-2} \text{ m/s}^{2}}
$$

- 72. Assume that $y_0 = 0$ for each child is the level at which the child loses contact with the trampoline surface. Choose upward to be the positive direction.
	- (*a*) The second child has $v_{02} = 5.0 \text{ m/s}$, $a = -g = -9.8 \text{ m/s}^2$, and $v = 0 \text{ m/s}$ at the maximum height position. Find the child's maximum height from Eq. 2-11c, with *x* replaced by *y*.

$$
v^{2} = v_{02}^{2} + 2a(y_{2} - y_{0}) \rightarrow y_{2} = y_{0} + \frac{v^{2} - v_{02}^{2}}{2a} = 0 + \frac{0 - (5.0 \text{ m/s})^{2}}{2(-9.8 \text{ m/s}^{2})} = 1.276 \text{ m} \approx 1.3 \text{ m}
$$

(*b*) Since the first child can bounce up to one-and-a-half times higher than the second child, the first child can bounce up to a height of $1.5(1.276 \text{ m}) = 1.913 \text{ m} = y_1 - y_0$. Eq. 2-11c is again used to find the initial speed of the first child.

$$
v^{2} = v_{01}^{2} + 2a(y_{1} - y_{0}) \rightarrow
$$

\n
$$
v_{01} = \pm \sqrt{v^{2} - 2a(y_{1} - y_{0})} = \sqrt{0 - 2(-9.8 \text{ m/s}^{2})(1.913 \text{ m})} = 6.124 \text{ m/s} \approx 6.1 \text{ m/s}
$$

The positive root was chosen since the child was initially moving upward.

(*c*) To find the time that the first child was in the air, use Eq. 2-11b with a total displacement of 0, since the child returns to the original position.

$$
y = y_0 + v_{01}t_1 + \frac{1}{2}at_1^2 \rightarrow 0 = (6.124 \text{ m/s})t_1 + \frac{1}{2}(-9.8 \text{ m/s}^2)t_1^2 \rightarrow t_1 = 0 \text{ s}, 1.2497 \text{ s}
$$

The time of 0 s corresponds to the time the child started the jump, so the correct answer is $1.2 s$.

73. For the car to pass the train, the car must travel the length of the train AND the distance the train

travels. The distance the car travels can thus be written as either $d_{\text{car}} = v_{\text{car}} t = (95 \text{ km/h})t$ or $d_{\text{car}} = L_{\text{train}} + v_{\text{train}}t = 1.10 \text{ km} + (75 \text{ km/h})t$. To solve for the time, equate these two expressions $d_{\text{car}} = L_{\text{train}} + v_{\text{train}}t = 1.10 \text{ km} + (75 \text{ km/h})t$. To solve for the time, equate these two expressions for the distance the car travels.

$$
(95 \text{ km/h})t = 1.10 \text{ km} + (75 \text{ km/h})t \rightarrow t = \frac{1.10 \text{ km}}{20 \text{ km/h}} = 0.055 \text{ h} = 3.3 \text{ min}
$$

The distance the car travels during this time is $d = (95 \text{ km/h}) (0.055 \text{ h}) = 5.225 \text{ km} \approx 5.2 \text{ km}$.

If the train is traveling the opposite direction from the car, then the car must travel the length of the train MINUS the distance the train travels. Thus the distance the car travels can be written as either $d_{car} = (95 \text{ km/h})t$ or $d_{car} = 1.10 \text{ km} - (75 \text{ km/h})t$. To solve for the time, equate these two expressions for the distance the car travels.

$$
(95 \text{ km/h})t = 1.10 \text{ km} - (75 \text{ km/h})t \rightarrow t = \frac{1.10 \text{ km}}{170 \text{ km/h}} = 6.47 \times 10^{-3} \text{ h} = 23.3 \text{ s}
$$

The distance the car travels during this time is $d = (95 \text{ km/h}) (6.47 \times 10^{-3} \text{ h}) = 0.61 \text{ km}$.

74. For the baseball, $v_0 = 0$, $x - x_0 = 3.5$ m, and the final speed of the baseball (during the throwing motion) is $v = 44 \text{ m/s}$. The acceleration is found from Eq. 2-11c.

$$
v^2 = v_0^2 + 2a(x - x_0)
$$
 $\rightarrow a = \frac{v^2 - v_0^2}{2(x - x_0)} = \frac{(44 \text{ m/s})^2 - 0}{2(3.5 \text{ m})} = \boxed{280 \text{ m/s}^2}$

75. (*a*) Choose upward to be the positive direction, and $y_0 = 0$ at the ground. The rocket has $v_0 = 0$,
z = 2.2 m/ c^2 , and *y* = 1200 m when it was out of final. Find the velocity of the realist when it $a = 3.2 \text{ m/s}^2$, and $y = 1200 \text{ m}$ when it runs out of fuel. Find the velocity of the rocket when it runs out of fuel from Eq 2-11c, with *x* replaced by *y*. $v_{200}^2 = v_0^2 + 2a(v - v_0) \rightarrow$ $2a(y-y_0) \rightarrow$ $v_{1200\,\text{m}}^2 = v_0^2 + 2a(y - y_0) \rightarrow$

$$
v_{1200\,\text{m}} = v_0 + 2a(y - y_0)
$$

$$
v_{1200\,\text{m}} = \pm \sqrt{v_0^2 + 2a(y - y_0)} = \pm \sqrt{0 + 2(3.2\,\text{m/s}^2)(1200\,\text{m})} = 87.64\,\text{m/s} \approx \boxed{88\,\text{m/s}}
$$

The positive root is chosen since the rocket is moving upwards when it runs out of fuel.

(*b*) The time to reach the 1200 m location can be found from equation (2-11a).

$$
v_{1200 \text{ m}} = v_0 + at_{1200 \text{ m}} \rightarrow t_{1200 \text{ m}} = \frac{v_{1200 \text{ m}} - v_0}{a} = \frac{87.64 \text{ m/s} - 0}{3.2 \text{ m/s}^2} = 27.39 \text{ s} \approx 27 \text{ s}
$$

(*c*) For this part of the problem, the rocket will have an initial velocity $v_0 = 87.64 \text{ m/s}$, an $v_0 = 87.64 \text{ m/s}$, an acceleration of $a = -9.8 \text{ m/s}^2$, and a final velocity of $v = 0$ at its maximum altitude. The altitude reached from the out-of-fuel point can be found from equation (2-11c). $2a(y-1200 \text{ m}) \rightarrow$ $v^2 = v_{\text{non-m}}^2 + 2a(y - 1200 \text{ m}) \rightarrow$

$$
y_{\text{max}} = 1200 \text{ m} + \frac{0 - v_{1200 \text{ m}}^2}{2a} = 1200 \text{ m} + \frac{-(87.64 \text{ m/s})^2}{2(-9.8 \text{ m/s}^2)} = 1200 \text{ m} + 390 \text{ m} = \boxed{1590 \text{ m}}
$$

(*d*) The time for the "coasting" portion of the flight can be found from Eq. 2-11a.

$$
v = v_{1200 \text{ m}} + at_{\text{coast}}
$$
 $\rightarrow t_{\text{coast}} = \frac{v - v_0}{a} = \frac{0 - 87.64 \text{ m/s}}{-9.8 \text{ m/s}^2} = 8.94 \text{ s}$

Thus the total time to reach the maximum altitude is $t = 27 \text{ s} + 8.94 \text{ s} \approx 36 \text{ s}.$

(*e*) For this part of the problem, the rocket has $v_0 = 0$ m/s, $a = -9.8$ m/s², and a displacement of $a = -9.8 \text{ m/s}^2$, and a displacement of -1600 m (it falls from a height of 1600 m to the ground). Find the velocity upon reaching the Earth from Eq. 2-11c.

$$
v^{2} = v_{0}^{2} + 2a(y - y_{0}) \rightarrow
$$

$$
v = \pm \sqrt{v_{0}^{2} + 2a(y - y_{0})} = \pm \sqrt{0 + 2(-9.80 \text{ m/s}^{2})(-1600 \text{ m})} = -177 \text{ m/s}
$$

The negative root was chosen because the rocket is moving downward, which is the negative direction.

(*f*) The time for the rocket to fall back to the Earth is found from Eq. 2-11a.

$$
v = v_0 + at
$$
 \rightarrow $t_{\text{fall}} = \frac{v - v_0}{a} = \frac{-177 \text{ m/s} - 0}{-9.80 \text{ m/s}^2} = 18.1 \text{ s}$

Thus the total time for the entire flight is $t = 36 \text{ s} + 18.1 \text{ s} = \sqrt{54 \text{ s}}$.

- 76. The speed limit is $50 \text{ km/h} \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) = 13.89 \text{ m/s}.$ 1 m/s $\Big|$ 12.80 $\Big|$ 50 km/h $\frac{120 \text{ m/s}}{120 \text{ m/s}}$ = 13.89 m/s. 3.6 km/h $/$. A construction of the construction of th
	- (*a*) For your motion, you would need to travel $(10 + 15 + 50 + 15 + 70)$ m = 160 m to get through the third light. The time to travel the 160 m is found using the distance and the constant speed.

$$
d = \overline{v} t \rightarrow t = \frac{d}{\overline{v}} = \frac{160 \text{ m}}{13.89 \text{ m/s}} = 11.52 \text{ s}
$$

Yes , you can make it through all three lights without stopping.

(*b*) The second car needs to travel 150 m before the third light turns red. This car accelerates from $v_0 = 0$ m/s to a maximum of $v = 13.89$ m/s with $a = 2.0$ m/s². Use Eq. 2-11a to determine the duration of that acceleration.

$$
v = v_0 + at
$$
 \rightarrow $t_{acc} = \frac{v - v_0}{a} = \frac{13.89 \text{ m/s} - 0 \text{ m/s}}{2.0 \text{ m/s}^2} = 6.94 \text{ s}$

The distance traveled during that time is found from Eq. 2-11b.

$$
(x - x_0)_{\text{acc}} = v_0 t_{\text{acc}} + \frac{1}{2} a t_{\text{acc}}^2 = 0 + \frac{1}{2} (2.0 \text{ m/s}^2) (6.94 \text{ s})^2 = 48.2 \text{ m}.
$$

Since 6.94 sec have elapsed, there are $13 - 6.94 = 6.06$ sec remaining to clear the intersection. The car travels another 6 seconds at a speed of 13.89 m/s, covering a distance of $d_{\text{constant}} = \overline{v} t = (13.89 \text{ m/s})(6.06 \text{ s}) = 84.2 \text{ m}$. Thus the total distance is 48.2 m + 84.2 m = speed that the contract of the

132.4 m. \vert No \vert , the car cannot make it through all three lights without stopping.

77. Take the origin to be the location where the speeder passes the police car. The speeder's constant speed is $v_{\text{speeder}} = (120 \text{ km/h}) \left(\frac{1 \text{ m/s}}{2.51 \text{ m/s}} \right) = 33.3 \text{ m/s}$, and the location of the speeder as a function 3.6 km/h $\frac{1}{2}$ $v_{\text{specter}} = (120 \text{ km/h}) \left(\frac{120 \text{ km/h}}{1 \text{ m/s}} \right) = 33.3 \text{ m/s}$, and the location of the speeder as a function of time is given by $x_{\text{speeder}} = v_{\text{speeder}} t_{\text{speeder}} = (33.3 \text{ m/s}) t_{\text{speeder}}$. The police car has an initial velocity of $v_0 = 0 \text{ m/s}$ and a constant acceleration of a_{policy} . The location of the police car as a function of time is given by Eq. 2-11b. $\frac{1}{2}at^2 - \frac{1}{2}a$ t^2

$$
x_{\text{policy}} = v_0 t + \frac{1}{2} a t^2 = \frac{1}{2} a_{\text{policy}} t_{\text{policy}}^2.
$$

Police car

 A^4 – 72.7 III

 $x \mid$ Speeder \sim

 t_1

 $Speeder$ \overrightarrow{S}

 t_1

- (*a*) The position vs. time graphs would qualitatively look like the graph shown here.
- (*b*) The time to overtake the speeder occurs when the speeder Speeder has gone a distance of 750 m. The time is found using the speeder's equation from above.

750 m = (33.3 m/s)
$$
t_{\text{speeder}}
$$
 $\rightarrow t_{\text{speeder}} = \frac{750 \text{ m}}{33.3 \text{ m/s}} = 22.5 \text{ s} \approx 23 \text{ s}$

(*c*) The police car's acceleration can be calculated knowing that the police car also had gone a distance of 750 m in a time of 22.5 s.

$$
750 \text{ m} = \frac{1}{2} a_p \left(22.5 \text{ s} \right)^2 \rightarrow a_p = \frac{2 (750 \text{ m})}{\left(22.5 \text{ s} \right)^2} = 2.96 \text{ m/s}^2 \approx 3.0 \text{ m/s}^2
$$

(*d*) The speed of the police car at the overtaking point can be found from Eq. 2-11a.

$$
v = v_0 + at = 0 + (2.96 \text{ m/s}^2)(22.5 \text{ s}) = 66.67 \text{ m/s} \approx 67 \text{ m/s}
$$

Note that this is exactly twice the speed of the speeder.

78. Choose downward to be the positive direction, and the origin to be at the roof of the building from which the stones were dropped. The first stone has $y_0 = 0$, $v_0 = 0$, a final location of $y = H$ (as yet unknown), and $a = g$. If the time for the first stone to reach the ground is t_1 , then Eq. 2-11c gives the following, replacing *x* with *y*:

$$
y = y_0 + v_0 t + \frac{1}{2} a t^2 \rightarrow H = \frac{1}{2} (9.80 \text{ m/s}^2) t_1^2
$$
.

The second stone has $v_0 = 25.0 \text{ m/s}$, $y_0 = 0$, a final location of $y = H$, and $a = g$. The time for the second stone to reach the ground is $t_1 - 2.00$ s, and so Eq. 2-11c for the second stone is $t_1 - 2.00$ s, and so Eq. 2-11c for the second stone is $20 \text{ m} \cdot \frac{1}{2} (t_1 - 2.00)^2$

$$
H = (25.0 \,\mathrm{m/s})(t_1 - 2.00) + \frac{1}{2}(9.80 \,\mathrm{m/s}^2)(t_1 - 2.00)^2.
$$

(*a*) Set the two expressions for *H* equal to each other, and solve for t_1 . t_1 .

$$
\frac{1}{2}(9.80 \text{ m/s}^2)t_1^2 = (25.0 \text{ m/s})(t_1 - 2) + \frac{1}{2}(9.80 \text{ m/s}^2)(t_1 - 2)^2 \rightarrow t_1 = 5.63 \text{ s}
$$

(*b*) The building height is given by $H = \frac{1}{2}gt_1^2 = \frac{1}{2}(9.80 \text{ m/s}^2)(5.63 \text{ s})^2 = 155 \text{ m}.$

(c) The speed of the stones is found using Eq. 2-11a.
\n
$$
\#1: \ v = v_0 + at = gt_1 = (9.80 \text{ m/s}^2)(5.63 \text{ s}) = 55.2 \text{ m/s}
$$
\n
$$
\#2: \ v = v_0 + at = v_0 + g(t_1 - 2) = 25.0 \text{ m/s} + (9.80 \text{ m/s}^2)(3.63 \text{ s}) = 60.6 \text{ m/s}
$$

79. Choose upward to be the positive direction, and the origin to be at ground level. The initial velocity of the first stone is $v_{0A} = 11.0 \text{ m/s}$, and the acceleration of both stones is $a = -9.80 \text{ m/s}^2$. The $a = -9.80 \,\mathrm{m/s^2}$. The starting location is $y_{0A} = H_A$, and it takes 4.5 s for the stone to reach the final location $y = 0$. Use Eq. 2-11b (with *x* replaced by *y*) to find a value for H_A . . 2 ² ²

$$
y = y_0 + v_0 t + \frac{1}{2} a t^2 \rightarrow 0 = H_A + (11.0 \text{ m/s})(4.5 \text{ s}) - \frac{1}{2} (9.80 \text{ m/s}^2)(4.5 \text{ s})^2 \rightarrow
$$

$$
H_A = 49.7 \text{ m}
$$

Assume that the $12th$ floor balcony is three times higher above the ground than the $4th$ floor balcony. Thus the height of 4th floor balcony is $\frac{1}{3}(49.7 \text{ m}) = 16.6 \text{ m}$. So for the second stone, $y_{0B} = 16.6 \text{ m}$, $y_{0B} = 16.6$ m, 16.6 m ,

and it takes 4.5 s for the stone to reach the final location $y = 0$. Use Eq. 2-11b to find the starting velocity, v_{0B} . v_{0R} .

$$
y = y_0 + v_0 t + \frac{1}{2} a t^2 \rightarrow 0 = 16.6 \text{ m} + v_{0B} (4.5 \text{ s}) - \frac{1}{2} (9.80 \text{ m/s}^2) (4.5 \text{ s})^2 \rightarrow
$$

$$
v_{0B} = 18 \text{ m/s}
$$

80. Choose downward to be the positive direction, and the origin to be at the location of the plane. The parachutist has $v_0 = 0$, $a = g = 9.8 \text{ m/s}^2$, and will have $y - y_0 = 2850 \text{ m}$ when she pulls the ripcord. Eq. 2-11b, with *x* replaced by *y*, is used to find the time when she pulls the ripcord.

$$
y = y_0 + v_0 t + \frac{1}{2} a t^2 \rightarrow t = \sqrt{2 (y - y_0)} / a = \sqrt{2 (2850 \text{ m}) / (9.80 \text{ m/s}^2)} = 24.1 \text{ s}
$$

The speed is found from Eq. 2-11a.

$$
v = v_0 + at = 0 + (9.80 \text{ m/s}^2)(24.1 \text{ s}) = 236 \text{ m/s} \approx 2.3 \times 10^2 \text{ m/s} = 850 \text{ km/h}
$$

81. The speed of the conveyor belt is given by $d = \overline{v}\Delta t \rightarrow \overline{v} = \frac{d}{v} = \frac{1.1 \text{ m}}{1.1 \text{ m}} = \boxed{0.44 \text{ m/min}}$. The rate 0.44 m/min. The rate 2.5 min $d = \overline{v}\Delta t \rightarrow \overline{v} = \frac{d}{v} = \frac{1.1 \text{ m}}{1.1 \text{ m}} = \boxed{0.44 \text{ m/min}}$. The rate $t = 2.5$ min . The rate of burger production, assuming the spacing given is center to center, can be found as

$$
\left(\frac{1 \text{ burger}}{0.15 \text{ m}}\right)\left(\frac{0.44 \text{ m}}{1 \text{ min}}\right) = 2.9 \frac{\text{burgers}}{\text{min}}.
$$

82. Choose upward to be the positive direction, and the origin to be at the level where the ball was thrown. The velocity at the top of the ball's path will be $v = 0$, and the ball will have an acceleration of $a = -g$. If the maximum height that the ball reaches is $y = H$, then the relationship between the initial velocity and the maximum height can be found from Eq. 2-11c, with *x* replaced by *y*.

$$
v^2 = v_0^2 + 2a(y - y_0) \rightarrow 0 = v_0^2 + 2(-g)H \rightarrow H = v_0^2/2g.
$$

$$
v^{2} = v_{0}^{2} + 2a(y - y_{0}) \rightarrow 0 = v_{0}^{2} + 2(-g)H \rightarrow H = v_{0}^{2}/2g.
$$

We are told that $v_{0 \text{ Bill}} = 1.5v_{0 \text{ Joe}}$, so $\frac{H_{\text{Bill}}}{H_{\text{Joe}}} = \frac{(v_{0 \text{ Bill}})^{2}/2g}{(v_{0 \text{ Joe}})^{2}/2g} = \frac{(v_{0 \text{ Bill}})^{2}}{(v_{0 \text{ Joe}})^{2}} = 1.5^{2} = 2.25 \approx 2.3$.

83. As shown in problem 41, the speed with which the ball was thrown upward is the same as its speed on returning to the ground. From the symmetry of the two motions (both motions have speed $= 0$ at top, have same distance traveled and have same acceleration), the time for the ball to rise is 1.2 s. Choose upward to be the positive direction, and the origin to be at the level where the ball was thrown. For the ball, $v = 0$ at the top of the motion, and $a = -g$. Find the initial velocity from Eq. 2-11a.

$$
v = v_0 + at
$$
 $\rightarrow v_0 = v - at = 0 - (-9.80 \text{ m/s}^2)(1.2 \text{ s}) = 12 \text{ m/s}$

84. Choose downward to be the positive direction, and the origin to be at the top of the building. The barometer has $y_0 = 0$, $v_0 = 0$, and $a = g = 9.8 \text{ m/s}^2$. Use Eq. 2-11b to find the height of the building, with *x* replaced by *y*.

$$
y = y_0 + v_0 t + \frac{1}{2} a t^2 = 0 + 0 + \frac{1}{2} (9.8 \text{ m/s}^2) t^2
$$

\n
$$
y_{t=2.0} = \frac{1}{2} (9.8 \text{ m/s}^2) (2.0 \text{ s})^2 = 20 \text{ m}
$$

\n
$$
y_{t=2.3} = \frac{1}{2} (9.8 \text{ m/s}^2) (2.3 \text{ s})^2 = 26 \text{ m}
$$

\nThe difference in the estimates is 6 m.

The intent of the method was probably to use the change in air pressure between the ground level and the top of the building to find the height of the building. The very small difference in time measurements, which could be due to human reaction time, makes a 6 m difference in the height. This could be as much as 2 floors in error.

- 85. (*a*) The two bicycles will have the same velocity at any time when the instantaneous slopes of their *x* vs. *t* graphs are the same. That occurs near the time t_1 as marked on the graph.
	- (*b*) Bicycle A has the larger acceleration, because its graph is concave upward, indicating a positive acceleration. Bicycle B has no acceleration because its graph has a constant slope.

- (*c*) The bicycles are passing each other at the times when the two graphs cross, because they both have the same position at that time. The graph with the steepest slope is the faster bicycle, and so is the one that is passing at that instant. So at the first crossing, bicycle B is passing bicycle A. At the second crossing, bicycle A is passing bicycle B.
- (*d*) Bicycle B has the highest instantaneous velocity at all times until the time t_1 , where both graphs have the same slope. For all times after t_1 , bicycle A has the highest instantaneous velocity. The largest instantaneous velocity is for bicycle A at the latest time shown on the graph.
- (*e*) The bicycles appear to have the same average velocity. If the starting point of the graph for a particular bicycle is connected to the ending point with a straight line, the slope of that line is the average velocity. Both appear to have the same slope for that "average" line.

CHAPTER 3: Kinematics in Two Dimensions; Vectors

Answers to Questions

- 1. Their velocities are NOT equal, because the two velocities have different directions.
- 2. (*a*) During one year, the Earth travels a distance equal to the circumference of its orbit, but has a displacement of 0 relative to the Sun.
	- (*b*) The space shuttle travels a large distance during any flight, but the displacement from one launch to the next is 0.
	- (*c*) Any kind of cross country "round trip" air travel would result in a large distance traveled, but a displacement of 0.
	- (*d*) The displacement for a race car from the start to the finish of the Indy 500 auto race is 0.
- 3. The displacement can be thought of as the "straight line" path from the initial location to the final location. The length of path will always be greater than or equal to the displacement, because the displacement is the shortest distance between the two locations. Thus the displacement can never be longer than the length of path, but it can be less. For any path that is not a single straight line segment, the length of path will be longer than the displacement.
- 4. Since both the batter and the ball started their motion at the same location (where the ball was hit) and ended their motion at the same location (where the ball was caught), the displacement of both was the same.
- 5. The magnitude of the vector sum need not be larger than the magnitude of either contributing vector. For example, if the two vectors being added are the exact opposite of each other, the vector sum will have a magnitude of 0. The magnitude of the sum is determined by the angle between the two contributing vectors.
- 6. If the two vectors are in the same direction, the magnitude of their sum will be a maximum, and will be 7.5 km. If the two vectors are in the opposite direction, the magnitude of their sum will be a minimum, and will be 0.5 km. If the two vectors are oriented in any other configuration, the magnitude of their sum will be between 0.5 km and 7.5 km.
- 7. Two vectors of unequal magnitude can never add to give the zero vector. However, three vectors of unequal magnitude can add to give the zero vector. If their geometric sum using the tail-to-tip method gives a closed triangle,

- then the vector sum will be zero. See the diagram, in which $\vec{A} + \vec{B} + \vec{C} = 0$
8. (*a*) The magnitude of a vector can equal the length of one of its components if the other components of the vector are all 0; i.e. if the vector lies along one of the coordinate axes.
	- (*b*) The magnitude of a vector can never be less than one of its components, because each component contributes a positive amount to the overall magnitude, through the Pythagorean relationship. The square root of a sum of squares is never less than the absolute value of any individual term.
- 9. A particle with constant speed can be accelerating, if its direction is changing. Driving on a curved roadway at constant speed would be an example. However, a particle with constant velocity cannot be accelerating – its acceleration must be zero. It has both constant speed and constant direction.

10. To find the initial speed, use the slingshot to shoot the rock directly horizontally (no initial vertical speed) from a height of 1 meter. The vertical displacement of the rock can be related to the time of flight by Eq. 2-11b. Take downward to be positive.

$$
y = y_0 + v_{y0}t + \frac{1}{2}at^2 \rightarrow 1 \text{ m} = \frac{1}{2}gt^2 \rightarrow t = \sqrt{2(1 \text{ m})/(9.8 \text{ m/s}^2)} = 0.45 \text{ s}.
$$

Measure the horizontal range *R* of the rock with the meter stick. Then, if we measure the horizontal range *R*, we know that $R = v_x t = v_x (0.45 \text{ s})$, and so $v_x = R/0.45 \text{ s}$. The only measurements are the height of fall and the range, both of which can be measured by a meter stick.

- 11. Assume that the bullet was fired from behind and below the airplane. As the bullet rose in the air, its vertical speed would be slowed by both gravity and air resistance, and its horizontal speed would be slowed by air resistance. If the altitude of the airplane was slightly below the maximum height of the bullet, then at the altitude of the airplane, the bullet would be moving quite slowly in the vertical direction. If the bullet's horizontal speed had also slowed enough to approximately match the speed of the airplane, then the bullet's velocity relative to the airplane would be small. With the bullet moving slowly, it could safely be caught by hand.
- 12. The moving walkway will be moving at the same speed as the "car". Thus, if you are on the walkway, you are moving the same speed as the car. Your velocity relative to the car is 0, and it is easy to get into the car. But it is very difficult to keep your balance while trying to sit down into a moving car from a stationary platform. It is easier to keep your balance by stepping on to the moving platform while walking, and then getting into the car with a velocity of 0 relative to the car.
- 13. Your reference frame is that of the train you are riding. If you are traveling with a relatively constant velocity (not over a hill or around a curve or drastically changing speed), then you will interpret your reference frame as being at rest. Since you are moving forward faster than the other train, the other train is moving backwards relative to you. Seeing the other train go past your window from front to rear makes it look like the other train is going backwards. This is similar to passing a semi truck on the interstate – out of a passenger window, it looks like the truck is going backwards.
- 14. When you stand still under the umbrella in a vertical rain, you are in a cylinder-shaped volume in which there is no rain. The rain has no horizontal component of velocity, and so the rain cannot move from outside that cylinder into it. You stay dry. But as you run, you have a forward horizontal velocity relative to the rain, and so the rain has a backwards horizontal velocity relative to you. It is the same as if you were standing still under the umbrella but the rain had some horizontal component of velocity towards you. The perfectly vertical umbrella would not completely shield you.
- 15. (*a*) The ball lands at the same point from which it was thrown inside the train car back in the thrower's hand.
	- (*b*) If the car accelerates, the ball will land behind the point from which it was thrown.
	- (*c*) If the car decelerates, the ball will land in front of the point from which it was thrown.
	- (*d*) If the car rounds a curve (assume it curves to the right), then the ball will land to the left of the point from which it was thrown.
	- (*e*) The ball will be slowed by air resistance, and so will land behind the point from which it was thrown.
- 16. Both rowers need to cover the same "cross river" distance. The rower with the greatest speed in the "cross river" direction will be the one that reaches the other side first. The current has no bearing on the problem because the current doesn't help either of the boats move across the river. Thus the rower heading straight across will reach the other side first. All of his rowing effort has gone into

crossing the river. For the upstream rower, some of his rowing effort goes into battling the current, and so his "cross river" speed will be only a fraction of his rowing speed.

- 17. The baseball is hit and caught at approximately the same height, and so the range formula of 2 $R = v_0^2 \sin 2\theta_0/g$ is particularly applicable. Thus the baseball player is judging the initial speed of the ball and the initial angle at which the ball was hit.
- 18. The arrow should be aimed above the target, because gravity will deflect the arrow downward from a horizontal flight path. The angle of aim (above the horizontal) should increase as the distance from the target increases, because gravity will have more time to act in deflecting the arrow from a straight-line path. If we assume that the arrow when shot is at the same height as the target, then the range formula is applicable: $R = v_0^2 \sin 2\theta_0/g \rightarrow \theta = \frac{1}{2} \sin^{-1}(Rg/v_0^2)$. As the range and hence the argument of the inverse sine function increases, the angle increases.
- 19. The horizontal component of the velocity stays constant in projectile motion, assuming that air resistance is negligible. Thus the horizontal component of velocity 1.0 seconds after launch will be the same as the horizontal component of velocity 2.0 seconds after launch. In both cases the horizontal velocity will be given by $v_x = v_0 \cos \theta = (30 \text{ m/s})(\cos 30^\circ) = 26 \text{ m/s}.$ $c_x = v_0 \cos \theta = (30 \text{ m/s})(\cos 30^\circ) = 26 \text{ m/s}.$
- 20. (*a*) Cannonball A, with the larger angle, will reach a higher elevation. It has a larger initial vertical velocity, and so by Eq. 2-11c, will rise higher before the vertical component of velocity is 0.
	- (*b*) Cannonball A, with the larger angle, will stay in the air longer. It has a larger initial vertical velocity, and so takes more time to decelerate to 0 and start to fall.
	- (c) The cannonball with a launch angle closest to 45° will travel the farthest. The range is a maximum for a launch angle of 45° , and decreases for angles either larger or smaller than 45° . .

Solutions to Problems

- 1. The resultant vector displacement of the car is given by $\vec{\mathbf{D}}_{\text{R}} = \vec{\mathbf{D}}_{\text{west}} + \vec{\mathbf{D}}_{\text{south}}$. The westward displacement is $\vec{D}_R = \vec{D}_{\text{west}} + \vec{D}_{\text{south}}$. The westward displacement is \vec{D}_{south} $215 + 85 \cos 45^\circ = 275.1$ km and the south displacement is 85 sin 45° = 60.1 km. The resultant displacement has a magnitude of $\sqrt{275.1^2 + 60.1^2}$ = 281.6 km $275.1^2 + 60.1^2 = 281.6$ km 282 km. The direction is $\theta = \tan^{-1} 60.1 / 275.1 = 12.3^\circ \approx 12^\circ$ south of west. $\overrightarrow{D_R}$
 $\overrightarrow{D_R}$
 $\overrightarrow{D_{\text{rest}}}$
 $\overrightarrow{D_{\text{rest}}}$
 $\overrightarrow{D}_{\text{host}}$
 $\overrightarrow{D}_{\text{earth}}$
 $\overrightarrow{D}_{\text{scat}}$
 $\overrightarrow{D}_{\text{scath}}$
 $\overrightarrow{D}_{\text{scath}}$
 $\overrightarrow{D}_{\text{scath}}$
 $\overrightarrow{D}_{\text{scath}}$
 $\overrightarrow{D}_{\text{scath}}$
 $\overrightarrow{D}_{\text{scath}}$ south- \vec{r} $\overrightarrow{\mathbf{D}}_{\text{scatt}}$ **D**west
- 2. The truck has a displacement of $18 + (-16) = 2$ blocks north and 10 blocks east. The resultant has a magnitude of $\sqrt{2^2 + 10^2} = 10$ blocks and a direction \vec{p} of $\tan^{-1} 2/10 = 11^\circ$ north of east.

3. Label the "INCORRECT" vector as vector $\vec{\textbf{X}}$. Then Fig. 3-6 (c) illustrates the relationship $V_1 + X = V_2$ via the tail-to-tip method. Thus $X = |V_2 - V_1|$.

- 4. Given that $V_x = 6.80$ units and $V_y = -7.40$ units, the magnitude of \vec{V} is given by $V = \sqrt{V_x^2 + V_y^2} = \sqrt{6.80^2 + (-7.40)^2} = 10.0 \text{ units}$. The direction is given by an angle of $\theta = \tan^{-1} \frac{-7.40}{\pi} = \boxed{-47^{\circ}}$, or 47° below the positive x -6.80 , or 47° below the positive x - $\left\| \int \right\|$: axis. $\mathbf{L} \cdot \mathbf{L} \cdot \mathbf{N}$
- 5. The vectors for the problem are drawn approximately to scale. The resultant has a length of $\overline{58 \text{ m}}$ and a direction $\overline{48^\circ}$ north of east. If calculations are done, the actual resultant should be 57.4 m at 47.5^o $\vec{v}_p = \vec{v}_i + \vec{v}_p$ north of east.

 \mathbf{V}_x

x

y

6. The sum is found by adding the components of vectors \vec{V}_1 and \vec{V}_2 and V_2

$$
\vec{\mathbf{V}} = \vec{\mathbf{V}}_1 + \vec{\mathbf{V}}_2 = (8.0, -3.7, 0.0) + (3.9, -8.1, -4.4) = \boxed{(11.9, -11.8, -4.4)}
$$
\n
$$
V = |\vec{\mathbf{V}}| = \sqrt{(11.9)^2 + (-11.8)^2 + (-4.4)^2} = \boxed{17.3}
$$

7. (a) See the accompanying diagram
\n(b)
$$
V_x = -14.3 \cos 34.8^\circ = \boxed{-11.7 \text{ units}}
$$
 $V_y = 14.3 \sin 34.8^\circ = \boxed{8.16 \text{ units}}$
\n(c) $V = \sqrt{V_x^2 + V_y^2} = \sqrt{(-11.7)^2 + (8.16)^2} = \boxed{14.3 \text{ units}}$
\n $\theta = \tan^{-1} \frac{8.16}{11.7} = \boxed{34.8^\circ \text{ above the } -x \text{ axis}}$
\n8. (a) $V_{1x} = \boxed{-6.6 \text{ units}}$ $V_{1y} = \boxed{0 \text{ units}}$

$$
V_{2x} = 8.5 \cos 45^\circ = 6.0 \text{ units} \qquad V_{2y} = 8.5 \sin 45^\circ = 6.0 \text{ units}
$$

(b) $\vec{V}_1 + \vec{V}_2 = (V_{1x} + V_{2x}, V_{1y} + V_{2y}) = (-0.6, 6.0)$
 $|\vec{V}_1 + \vec{V}_2| = \sqrt{(-0.6)^2 + (6.0)^2} = 6.0 \text{ units} \qquad \theta = \tan^{-1} \frac{6.0}{0.6} = 84^\circ$

The sum has a magnitude of $\overline{6.0}$ units, and is $\overline{84^{\circ}}$ clockwise from the – negative x-axis, or 96^o counterclockwise from the positive x-axis.

9. (a)
$$
v_{\text{north}} = (735 \text{ km/h})(\cos 41.5^\circ) = 550 \text{ km/h}
$$
 $v_{\text{west}} = (735 \text{ km/h})(\sin 41.5^\circ) = 487 \text{ km/h}$
\n(b) $\Delta d_{\text{north}} = v_{\text{north}}t = (550 \text{ km/h})(3.00 \text{ h}) = 1650 \text{ km}$
\n $\Delta d_{\text{west}} = v_{\text{west}}t = (487 \text{ km/h})(3.00 \text{ h}) = 1460 \text{ km}$

$$
A_x = 44.0 \cos 28.0^\circ = 38.85
$$

\n
$$
A_y = 44.0 \sin 28.0^\circ = 20.66
$$

\n
$$
B_x = -26.5 \cos 56.0^\circ = -14.82
$$

\n
$$
B_y = 26.5 \sin 56.0^\circ = 21.97
$$

\n
$$
C_x = 31.0 \cos 270^\circ = 0.0
$$

\n
$$
C_y = 31.0 \sin 270^\circ = -31.0
$$

\n(a) $(\vec{A} + \vec{B} + \vec{C})_x = 38.85 + (-14.82) + 0.0 = 24.03 = 24.0$
\n
$$
(\vec{A} + \vec{B} + \vec{C})_y = 20.66 + 21.97 + (-31.0) = 11.63 = 11.6
$$

\n(b) $|\vec{A} + \vec{B} + \vec{C}| = \sqrt{(24.03)^2 + (11.63)^2} = 26.7$
\n $\theta = \tan^{-1} \frac{11.63}{24.03} = 25.8^\circ$

11.
$$
A_x = 44.0 \cos 28.0^\circ = 38.85
$$
 $A_y = 44.0 \sin 28.0^\circ = 20.66$
\n $C_x = 31.0 \cos 270^\circ = 0.0$ $C_y = 31.0 \sin 270^\circ = -31.0$
\n $(\vec{A} - \vec{C})_x = 38.85 - 0.0 = 38.85$ $(\vec{A} - \vec{C})_y = 20.66 - (-31.0) = 51.66$
\n $|\vec{A} - \vec{C}| = \sqrt{(38.85)^2 + (51.66)^2} = \boxed{64.6}$ $\theta = \tan^{-1} \frac{51.66}{38.85} = \boxed{53.1^\circ}$

12.
$$
A_x = 44.0 \cos 28.0^\circ = 38.85
$$
 $A_y = 44.0 \sin 28.0^\circ = 20.66$
 $B_x = -26.5 \cos 56.0^\circ = -14.82$ $B_y = 26.5 \sin 56.0^\circ = 21.97$

(*a*) $(\mathbf{B} - \mathbf{A})_x = (-14.82) - 38.85 = -53.67$ $(\mathbf{B} - \mathbf{A})_y = 21.97 - 20.66 = 1.31$

Note that since the *x* component is negative and the *y* component is positive, the vector is in the $2nd$ quadrant. $2nd$ quadrant. nd quadrant.

$$
\left|\vec{\mathbf{B}} - \vec{\mathbf{A}}\right| = \sqrt{\left(-53.67\right)^2 + \left(1.31\right)^2} = \boxed{53.7} \qquad \theta_{B-A} = \tan^{-1}\frac{1.31}{-53.67} = \boxed{1.4^\circ \text{ above } -x \text{ axis}}
$$
\n(b)
$$
\left(\vec{\mathbf{A}} - \vec{\mathbf{B}}\right)_x = 38.85 - \left(-14.82\right) = 53.67 \qquad \left(\vec{\mathbf{A}} - \vec{\mathbf{B}}\right)_y = 20.66 - 21.97 = -1.31
$$

Note that since the *x* component is positive and the *y* component is negative, the vector is in the $4th$ quadrant. th quadrant.

$$
|\vec{A} - \vec{B}| = \sqrt{(53.67)^2 + (-1.31)^2} = \boxed{53.7}
$$
 $\theta = \tan^{-1} \frac{-1.31}{53.7} = \boxed{1.4^{\circ} \text{ below} + x \text{ axis}}$

Comparing the results shows that $\vec{B} - \vec{A}$ is the opposite of $\vec{A} - \vec{B}$.

- 13. $A_x = 44.0 \cos 28.0^\circ = 38.85$ $A_y = 44.0 \sin 28.0^\circ = 20.66$
	- $S_x = -26.5 \cos 56.0^\circ = -14.82$ $B_y = 26.5 \sin 56.0^\circ = 21.97$
	- $C_x = 31.0 \cos 270^\circ = 0.0$ $C_y = 31.0 \sin 270^\circ = -31.0$ $B_x = -26.5 \cos 56.0^\circ = -14.82$ $B_y = 26.5 \sin 56.0^\circ = 21.97$
 $C_x = 31.0 \cos 270^\circ = 0.0$ $C_y = 31.0 \sin 270^\circ = -31.0$
	- (a) $(A B + C)$ _x = 38.85 (-14.82) + 0.0 = 53.67 $\mathbf{A} - \mathbf{B} + \mathbf{C}$ _y = 20.66 - 21.97 + (-31.0) = -32.31

Note that since the *x* component is positive and the *y* component is negative, the vector is in the $4th$ quadrant. $4th$ quadrant. th quadrant.

$$
|\vec{A} - \vec{B} + \vec{C}| = \sqrt{(53.67)^2 + (-32.31)^2} = \boxed{62.6}
$$
 $\theta = \tan^{-1} \frac{-32.31}{53.67} = \boxed{31.0^{\circ} \text{ below} + x \text{ axis}}$

(b)
$$
(\vec{A} + \vec{B} - \vec{C})_x = 38.85 + (-14.82) - 0.0 = 24.03
$$

\n $(\vec{A} + \vec{B} - \vec{C})_y = 20.66 + 21.97 - (-31.0) = 73.63$
\n $|\vec{A} + \vec{B} - \vec{C}| = \sqrt{(24.03)^2 + (73.63)^2} = \boxed{77.5}$ $\theta = \tan^{-1} \frac{73.63}{24.03} = \boxed{71.9^\circ}$
\n(c) $(\vec{C} - \vec{A} - \vec{B})_x = 0.0 - 38.85 - (-14.82) = -24.03$
\n $(\vec{C} - \vec{A} - \vec{B})_y = -31.0 - 20.66 - 21.97 = -73.63$
\nNote that since both components are negative, the vector is in the 3rd quadrant.
\n $|\vec{C} - \vec{A} - \vec{B}| = \sqrt{(-24.03)^2 + (-73.63)^2} = \boxed{77.5}$ $\theta = \tan^{-1} \frac{-73.63}{-24.03} = \boxed{71.9^\circ \text{ below} - x \text{ axis}}$
\nNote that the answer to (c) is the exact opposite of the answer to (b).
\n14. $A_x = 44.0 \cos 28.0^\circ = 38.85$ $A_y = 44.0 \sin 28.0^\circ = 20.66$
\n $B_x = -26.5 \cos 56.0^\circ = -14.82$ $B_y = 26.5 \sin 56.0^\circ = 21.97$
\n $C_x = 31.0 \cos 270^\circ = 0.0$ $C_y = 31.0 \sin 270^\circ = -31.0$
\n(a) $(\vec{B} - 2\vec{A})_x = -14.82 - 2(38.85) = -92.52$ $(\vec{B} - 2\vec{A})_y = 21.97 - 2(20.66) = -19.35$
\nNote that since both components are negative, the vector is in the 3

Note that since the *x* component is positive and the *y* component is negative, the vector is in the $4th$ quadrant. th quadrant.

$$
\left|2\vec{\mathbf{A}} - 3\vec{\mathbf{B}} + 2\vec{\mathbf{C}}\right| = \sqrt{\left(122.16\right)^2 + \left(-86.59\right)^2} = \boxed{149.7} \qquad \theta = \tan^{-1}\frac{-86.59}{122.16} = \boxed{35.3^{\circ} \text{ below} + x \text{ axis}}
$$

15. The *x* component is negative and the *y* component is positive, since the summit is to the west of north. The angle measured counterclockwise from the positive x axis would be 122.4°. Thus the . Thus the components are found to be $(1580 \text{ cm})^2$ $(1580 \text{ cm})^2$

$$
x = -4580 \sin 32.4^{\circ} = -2454 \text{ m}
$$

\n
$$
\vec{r} = (-2450 \text{ m}, 3870 \text{ m}, 2450 \text{ m})
$$

\n
$$
\vec{r} = \sqrt{(-2454)^{2} + (4580)^{2} + (2450)^{2}} = \boxed{5190 \text{ m}}
$$

\n16. 70.0 = $\sqrt{x^{2} + (-55.0)^{2}}$ \rightarrow 4900 = $x^{2} + 3025$ \rightarrow $x^{2} = 1875$ \rightarrow $x = \boxed{\pm 43.3 \text{ units}}$

17. Choose downward to be the positive *y* direction. The origin will be at the point where the tiger leaps from the rock. In the horizontal direction, $v_{x0} = 3.5 \text{ m/s}$ and $a_x = 0$. In the vertical direction, from the rock. In the horizontal direction, $v_{x0} = 3.5 \text{ m/s}$ and $a_x = 0$. In the vertical direction,
 $v_{y0} = 0$, $a_y = 9.80 \text{ m/s}^2$, $y_0 = 0$, and the final location $y = 6.5 \text{ m}$. The time for the tiger to reach the ground is found from applying Eq. 2-11b to the vertical motion.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \quad \rightarrow \quad 6.5 \text{m} = 0 + 0 + \frac{1}{2}(9.8 \text{ m/s}^2)t^2 \quad \rightarrow \quad t = \sqrt{\frac{2(6.5 \text{ m})}{9.8 \text{ m/s}^2}} = 1.15 \text{ sec}
$$

The horizontal displacement is calculated from the constant horizontal velocity.

 $\Delta x = v_t t = (3.5 \text{ m/s})(1.15 \text{ sec}) = 4.0 \text{ m}$ $t = (3.5 \text{ m/s})(1.15 \text{ sec}) = 4.0 \text{ m}$

18. Choose downward to be the positive *y* direction. The origin will be at the point where the diver dives from the cliff. In the horizontal direction, $v_{x0} = 1.8 \text{ m/s}$ and $a_x = 0$. In the vertical direction, dives from the cliff. In the horizontal direction, $v_{x0} = 1.8 \text{ m/s}$ and $a_x = 0$. In the vertical direction, $v_{y0} = 0$, $a_y = 9.80 \text{ m/s}^2$, $y_0 = 0$, and the time of flight is $t = 3.0 \text{ s}$. The height of the cliff is f from applying Eq. 2-11b to the vertical motion.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \quad \rightarrow \quad y = 0 + 0 + \frac{1}{2}(9.80 \text{ m/s}^2)(3.0 \text{ s})^2 = 44 \text{ m}
$$

The distance from the base of the cliff to where the diver hits the water is found from the horizontal motion at constant velocity:

$$
\Delta x = v_x t = (1.8 \text{ m/s})(3 \text{ s}) = 5.4 \text{ m}
$$

19. Apply the range formula from Example 3-8. 2

$$
R = \frac{v_0^2 \sin 2\theta_0}{g} \rightarrow
$$

\n
$$
\sin 2\theta_0 = \frac{Rg}{v_0^2} = \frac{(2.0 \text{ m})(9.8 \text{ m/s}^2)}{(6.8 \text{ m/s})^2} = 0.4239
$$

\n
$$
2\theta_0 = \sin^{-1} 0.4239 \rightarrow \theta_0 = [13^\circ, 77^\circ]
$$

There are two angles because each angle gives the same range. If one angle is $\theta = 45^\circ + \delta$, then $\theta = 45^\circ - \delta$ is also $\begin{vmatrix} 0 & \frac{\delta}{\delta} \\ 0 & \frac{\delta}{\delta} \end{vmatrix}$ a solution. The two paths are shown in the graph.

20. Choose upward to be the positive *y* direction. The origin is the point from which the pebbles are released. In the vertical direction, $a_y = -9.80 \text{ m/s}^2$, the velocity at the window is $v_y = 0$, and the $v_y = 0$, and the vertical displacement is 4.5 m. The initial *y* velocity is found from Eq. 2-11c.

$$
v_y^2 = v_{y0}^2 + 2a_y (y - y_0) \rightarrow
$$

\n
$$
v_{y0} = \sqrt{v_y^2 - 2a_y (y - y_0)} = \sqrt{0 - 2(-9.80 \text{ m/s}^2)(4.5 \text{ m})} = 9.39 \text{ m/s}
$$

Find the time for the pebbles to travel to the window from Eq. 2-11a.

$$
v_y = v_{y0} + at
$$
 \rightarrow $t = \frac{v_y - v_{y0}}{a} = \frac{0 - 9.4 \text{ m/s}}{-9.8 \text{ m/s}^2} = 0.958 \text{ s}$

Find the horizontal speed from the horizontal motion at constant velocity.

$$
\Delta x = v_x t \quad \to \quad v_x = \Delta x / t = 5.0 \text{ m} / 0.958 \text{ s} = 5.2 \text{ m} / \text{s}
$$

This is the speed of the pebbles when they hit the window.

21. Choose downward to be the positive *y* direction. The origin will be at the point where the ball is thrown from the roof of the building. In the vertical direction, $v_{y0} = 0$, $a_y = 9.80 \text{ m/s}^2$, $y_0 = 0$, and $a_y = 9.80 \text{ m/s}^2$, $y_0 = 0$, and $y_0 = 0$, and the displacement is 45.0 m. The time of flight is found from applying Eq. 2-11b to the vertical a solution. The two paths are shown in the graph.

Choose upward to be the positive y direction. The origin is the point from which the pebbles are

released. In the vertical direction, $a_y = -9.80 \text{ m/s}^2$, the velocity at

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

,

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2
$$
 \rightarrow 45.0 m = $\frac{1}{2}$ (9.80 m/s²) t^2 \rightarrow $t = \sqrt{\frac{2(45.0 \text{ m})}{9.80 \text{ m/s}^2}}$ = 3.03 sec

The horizontal speed (which is the initial speed) is found from the horizontal motion at constant velocity:

$$
\Delta x = v_x t \rightarrow v_x = \Delta x / t = 24.0 \text{ m} / 3.03 \text{ s} = 7.92 \text{ m} / \text{s}.
$$

22. Choose the point at which the football is kicked the origin, and choose upward to be the positive *y* direction. When the football reaches the ground again, the *y* displacement is 0. For the football, $v_{y0} = (18.0 \sin 35.0^\circ)$ m/s, $a_y = -9.80$ m/s² and the final y velocity will be the opposite of the starting *y* velocity (reference problem 3-28). Use Eq. 2-11a to find the time of flight.

$$
v_y = v_{y0} + at
$$
 \rightarrow $t = \frac{v_y - v_{y0}}{a} = \frac{(-18.0 \sin 35.0^{\circ}) \text{m/s} - (18.0 \sin 35.0^{\circ}) \text{m/s}}{-9.80 \text{m/s}^2} = 2.11 \text{ s}$

23. Choose downward to be the positive *y* direction. The origin is the point where the ball is thrown from the roof of the building. In the vertical direction, $v_{y0} = 0$, $y_0 = 0$, and $a_y = 9.80 \text{ m/s}^2$. The $a_y = 9.80 \,\mathrm{m/s^2}$. The initial horizontal velocity is 22.2 m/s and the horizontal range is 36.0 m. The time of flight is found from the horizontal motion at constant velocity.

$$
\Delta x = v_x t \rightarrow t = \Delta x / v_x = 36.0 \text{ m} / 22.2 \text{ m} / \text{s} = 1.62 \text{ s}
$$

The vertical displacement, which is the height of the building, is found by applying Eq. 2-11b to the vertical motion.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \quad \rightarrow \quad y = 0 + 0 + \frac{1}{2}(9.80 \text{ m/s}^2)(1.62 \text{ s})^2 = 12.9 \text{ m}
$$

24. (*a*) Use the "Level horizontal range" formula from Example 3-8.

$$
R = \frac{v_0^2 \sin 2\theta_0}{g} \quad \rightarrow \quad v_0 = \sqrt{\frac{Rg}{\sin 2\theta_0}} = \sqrt{\frac{(7.80 \text{ m})(9.80 \text{ m/s}^2)}{\sin 2(28.0^\circ)}} = \boxed{9.60 \text{ m/s}}
$$

(*b*) Now increase the speed by 5.0% and calculate the new range. The new speed would be 9.60 m/s (1.05) = 10.1 m/s and the new range would be
 $v^2 \sin 2\theta$ (10.1 m/s)² sin 2(28.0°)

$$
R = \frac{v_0^2 \sin 2\theta_0}{g} = \frac{(10.1 \text{ m/s})^2 \sin 2(28.0^\circ)}{9.80 \text{ m/s}^2} = 8.60 \text{ m},
$$

an increase of $\overline{0.80 \text{ m } (10\% \text{ increase})}$.

25. Calculate the range as derived in Example 3-8: $R = \frac{v_0^2 \sin 2\theta_0}{r}$. If the launching speed and angle *g* . If the launching speed and angle are held constant, the range is inversely proportional to the value of *g* . The acceleration due to gravity on the Moon is $1/6^{th}$ that on Earth.

$$
R_{\text{Earth}} = \frac{v_0^2 \sin 2\theta_0}{g_{\text{Earth}}} \qquad R_{\text{Moon}} = \frac{v_0^2 \sin 2\theta_0}{g_{\text{Moon}}} \qquad \rightarrow \qquad R_{\text{Earth}} g_{\text{Earth}} = R_{\text{Moon}} g_{\text{Moon}}
$$

$$
R_{\text{Moon}} = R_{\text{Earth}} \frac{g_{\text{Earth}}}{g_{\text{Moon}}} = 6R_{\text{Earth}}
$$

Thus on the Moon, the person can jump $\vert 6$ times farther.

26. (*a*) Choose downward to be the positive *y* direction. The origin is the point where the bullet leaves the gun. In the vertical direction, $v_{y0} = 0$, $y_0 = 0$, and $a_y = 9.80 \text{ m/s}^2$. In the $a_y = 9.80 \,\text{m/s}^2$. In the horizontal direction, $\Delta x = 75.0$ m and $v_x = 180$ m/s. The time of flight is found from the horizontal motion at constant velocity.

$$
\Delta x = v_x t \quad \rightarrow \quad t = \Delta x / v_x = 75.0 \text{ m} / 180 \text{ m} / \text{s} = 0.4167 \text{ s}
$$

This time can now be used in Eq. 2-11b to find the vertical drop of the bullet.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \quad \rightarrow \quad y = 0 + 0 + \frac{1}{2}(9.80 \text{ m/s}^2)(0.4167 \text{ s})^2 = 0.851 \text{ m}
$$

(*b*) For the bullet to hit the target at the same level, the level horizontal range formula of Example 3-8 applies. The range is 75.0 m, and the initial velocity is 180 m/s. Solving for the angle of launch results in the following.
 (7.8×10^{12})

$$
R = \frac{v_0^2 \sin 2\theta_0}{g} \quad \to \quad \sin 2\theta_0 = \frac{Rg}{v_0^2} \quad \to \quad \theta_0 = \frac{1}{2} \sin^{-1} \frac{(75.0 \text{ m})(9.80 \text{ m/s}^2)}{(180 \text{ m/s})^2} = 0.650^\circ
$$

Because of the symmetry of the range formula, there is also an answer of the complement of the above answer, which would be 89.35° . That is an unreasonable answer from a practical physical viewpoint – it is pointing the gun almost straight up.

- 27. Choose downward to be the positive *y* direction. The origin is the point where the supplies are dropped. In the vertical direction, $v_{y0} = 0$, $a_y = 9.80 \text{ m/s}^2$, $y_0 = 0$, and the final position is
	- $y = 160$ m. The time of flight is found from applying Eq. 2-11b to the vertical motion.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \rightarrow 160 \text{ m} = 0 + 0 + \frac{1}{2}(9.80 \text{ m/s}^2)t^2 \rightarrow
$$

$$
t = \sqrt{\frac{2(160 \text{ m})}{9.80 \text{ m/s}^2}} = \boxed{5.71 \text{ s}}
$$

Note that the speed of the airplane does not enter into this calculation.

- 28. The horizontal component of the speed does not change during the course of the motion, and so $v_{xf} = v_{x0}$. The net vertical displacement is 0 if the firing level equals the landing level. Eq. 2-11c then gives $v_{y}^2 = v_{y0}^2 + 2a_y \Delta y = v_{y0}^2$. Thus $v_{y}^2 = v_{y0}^2$, and from the horizontal $v_{x}^2 = v_{x0}^2$. The initial $x_f - v_{x0}$. The initial speed is $v_0 = \sqrt{v_{y0}^2 + v_{x0}^2}$. The final speed is $v_f = \sqrt{v_{yf}^2 + v_{xf}^2} = \sqrt{v_{y0}^2 + v_{x0}^2} = v_0$. Thus $\boxed{v_f = v_0}$.
29. Choose upward to be the positive y direction. The origin is point from which the football is
- The initial speed of the football is $v_0 = 20.0$ m/s. We have $v_{y0} = v_0 \sin 37.0^\circ = 12.04$ m/s, $y_0 = 0$, $s_{\rm y0} = v_{\rm 0} \sin 37.0^{\circ} = 12.04 \,\rm m/s$, $y_{\rm 0} = 0$, The initial speed of the football is $v_0 = 20.0 \text{ m/s}$. We have $v_{y0} = v_0 \sin 37.0^\circ = 12.04 \text{ m/s}$, $y_0 = 0$,
and $a_y = -9.80 \text{ m/s}^2$. In the horizontal direction, $v_x = v_0 \cos 37.0^\circ = 15.97 \text{ m/s}$, and $\Delta x = 36.0 \text{ m}$. and $a_y = -9.80 \text{ m/s}^2$. In the horizontal direction, $v_x = v_0 \cos 37.0^\circ = 15.97 \text{ m/s}$, and $\Delta x = 36.0 \text{ m}$.
The time of flight to reach the goalposts is found from the horizontal motion at constant speed: $x = v_x t \rightarrow t = \Delta x / v_x = 36.0 \text{ m} / 15.97 \text{ m} / \text{s} = 2.254 \text{ s}.$

Now use this time with the vertical motion data and Eq. 2-11b to find the height of the football when it reaches the horizontal location of the goalposts.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 = 0 + (12.04 \text{ m/s})(2.254 \text{ s}) + \frac{1}{2}(-9.80 \text{ m/s}^2)(2.254 \text{ s})^2 = 2.24 \text{ m}
$$

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Since the ball's height is less than 3.00 m , the football does not clear the bar. It is 0.76 m too low when it reaches the horizontal location of the goalposts.

- 30. Choose the origin to be where the projectile is launched, and upwards to be the positive *y* direction. The initial velocity of the projectile is v_0 , the launching angle is θ_0 , $a_y = -g$, and $v_{y0} = v_0 \sin \theta_0$. v_y ₀ = $v_0 \sin \theta_0$.
	- The initial velocity of the projectile is v_0 , the launching angle is θ_0 , $a_y = -g$, and $v_{y0} = v_0 \sin \theta_0$.

	(*a*) The maximum height is found from Eq. 2-11c, $v_y^2 = v_{y0}^2 + 2a_y (y y_0)$, with $v_y = 0$ at α_0 α_2 α_3 α_4 α_5 α_6 α_7 α_8 α_9 α_9 α_1 $v_y = 0$ at the maximum height.

$$
y_{\text{max}} = 0 + \frac{v_y^2 - v_{y0}^2}{2a_y} = \frac{-v_0^2 \sin^2 \theta_0}{-2g} = \frac{v_0^2 \sin^2 \theta_0}{2g} = \frac{(65.2 \text{ m/s})^2 \sin^2 34.5^\circ}{2(9.80 \text{ m/s}^2)} = \boxed{69.6 \text{ m}}
$$

(*b*) The total time in the air is found from Eq. 2-11b, with a total vertical displacement of 0 for the ball to reach the ground.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \rightarrow 0 = v_0 \sin \theta_0 t - \frac{1}{2}gt^2 \rightarrow t = \frac{2v_0 \sin \theta_0}{g} = \frac{2(65.2 \text{ m/s}) \sin 34.5^\circ}{(9.80 \text{ m/s}^2)} = \boxed{7.54 \text{ s}} \text{ and } t = 0
$$

The time of 0 represents the launching of the ball.

(*c*) The total horizontal distance covered is found from the horizontal motion at constant velocity.

$$
\Delta x = v_x t = (v_0 \cos \theta_0) t = (65.2 \,\text{m/s})(\cos 34.5^\circ)(7.54 \,\text{s}) = 405 \,\text{m}
$$

(*d*) The velocity of the projectile 1.50 s after firing is found as the vector sum of the horizontal and vertical velocities at that time. The horizontal velocity is a constant

 $v_0 \cos \theta_0 = (65.2 \text{ m/s})(\cos 34.5^\circ) = 53.7 \text{ m/s}$. The vertical velocity is found from Eq. 2-11a.

$$
v_y = v_{y0} + at = v_0 \sin \theta_0 - gt = (65.2 \text{ m/s}) \sin 34.5^\circ - (9.80 \text{ m/s}^2)(1.50 \text{ s}) = 22.2 \text{ m/s}
$$

Thus the speed of the projectile is $v = \sqrt{v_x^2 + v_y^2} = \sqrt{53.7^2 + 22.2^2} = \frac{58.1 \text{ m/s}}{58.1 \text{ m/s}}.$
The direction above the horizontal is given by $\theta = \tan^{-1} \frac{v_y}{v_x} = \tan^{-1} \frac{22.2}{53.7} = \frac{22.5^\circ}{22.5^\circ}.$

31. Choose the origin to be at ground level, under the place where the projectile is launched, and upwards to be the positive *y* direction. For the projectile, $v_0 = 65.0 \text{ m/s}$, $\theta_0 = 37.0^\circ$, $a_y = -g$, $y_0 = 125$, and $v_{y0} = v_0 \sin \theta_0$ 0° - 57.0 , u_{y}° - 8,

 $y_0 = 125$, and $v_{y0} = v_0 \sin \theta_0$ $\mathbf{y}_0 = \mathbf{v}_0 \sin \theta_0$ $v_{v0} = v_0 \sin \theta_0$

(*a*) The time taken to reach the ground is found from Eq. 2-11b, with a final height of 0.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \quad \to \quad 0 = 125 + v_0 \sin \theta_0 t - \frac{1}{2}gt^2 \quad \to
$$

$$
t = \frac{-v_0 \sin \theta_0 \pm \sqrt{v_0^2 \sin^2 \theta_0 - 4(-\frac{1}{2}g)(125)}}{2(-\frac{1}{2}g)} = \frac{-39.1 \pm 63.1}{-9.8} = 10.4 \text{ s}, -2.45 \text{ s} = \boxed{10.4 \text{ s}}
$$

Choose the positive sign since the projectile was launched at time $t = 0$.

(*b*) The horizontal range is found from the horizontal motion at constant velocity.

$$
\Delta x = v_x t = (v_0 \cos \theta_0) t = (65.0 \,\text{m/s}) \cos 37.0^{\circ} \, (10.4 \,\text{s}) = 541 \,\text{m}
$$

(*c*) At the instant just before the particle reaches the ground, the horizontal component of its velocity is the constant $v_x = v_0 \cos \theta_0 = (65.0 \text{ m/s}) \cos 37.0^\circ = |51.9 \text{ m/s}|$. The vertical

component is found from Eq. 2-11a.

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$
v_y = v_{y0} + at = v_0 \sin \theta_0 - gt = (65.0 \text{ m/s}) \sin 37.0^\circ - (9.80 \text{ m/s}^2)(10.4 \text{ s})
$$

=
$$
-63.1 \text{ m/s}
$$

(*d*) The magnitude of the velocity is found from the *x* and *y* components calculated in part *c*) above. $v = \sqrt{v_x^2 + v_y^2} = \sqrt{(51.9 \text{ m/s})^2 + (-63.1 \text{ m/s})^2} = |81.7 \text{ m/s}|$

(*e*) The direction of the velocity is $\theta = \tan^{-1} \frac{v_y}{v_x} = \tan^{-1} \frac{-63.1}{v_x} = -50.6^\circ$, and so the object is 51.9 \mathcal{F} to $^{-1}$ \mathcal{F} 0.3.1 \mathcal{F} 0.6% and so the shipping *x* $\frac{1}{2}$ $\frac{1}{2}$ $v_y = -63.1$ v_r 51.9 , and so the object is

moving $\overline{50.6^{\circ}}$ below the horizon 50.6° below the horizon.

(*f*) The maximum height above the cliff top reached by the projectile will occur when the y velocity is 0, and is found from Eq. 2-11c.

$$
v_y^2 = v_{y0}^2 + 2a_y (y - y_0) \rightarrow 0 = v_0^2 \sin^2 \theta_0 - 2gy_{\text{max}}
$$

$$
y_{\text{max}} = \frac{v_0^2 \sin^2 \theta_0}{2g} = \frac{(65.0 \text{ m/s})^2 \sin^2 37.0^\circ}{2(9.80 \text{ m/s}^2)} = 78.1 \text{ m}
$$

32. Choose the origin to be the point of release of the shot put. Choose upward to be the positive *y* direction. Then $y_0 = 0$, $v_{y0} = (15.5 \sin 34.0^\circ) \text{ m/s} = 8.67 \text{ m/s}$, $a_y = -9.80 \text{ m/s}^2$, and $a_y = -9.80 \,\mathrm{m/s^2}$, and

$$
y = -2.20
$$
 m at the end of the motion. Use Eq. 2-11b to find the time of flight.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \rightarrow \frac{1}{2}a_yt^2 + v_{y0}t - y = 0 \rightarrow
$$

$$
t = \frac{-v_{y0} \pm \sqrt{v_{y0}^2 - 4(\frac{1}{2}a_y)(-y)}}{2\frac{1}{2}a_y} = \frac{-8.67 \pm \sqrt{(8.67)^2 - 2(-9.80)(2.20)}}{-9.80} = 1.99 \text{ s}, -0.225 \text{ s}
$$

Choose the positive result since the time must be greater than 0. Now calculate the horizontal distance traveled using the horizontal motion at constant velocity.

$$
\Delta x = v_x t = (15.5 \cos 34^\circ) \text{ m/s} (1.99 \text{ s}) = 25.6 \text{ m}
$$

33. Choose the origin to be where the projectile is launched, and upwards to be the positive *y* direction. The initial velocity of the projectile is v_0 , the launching angle is θ_0 , $a_y = -g$, and $v_{y0} = v_0 \sin \theta_0$. v_y ₀ = $v_0 \sin \theta_0$.

The range of the projectile is given by the range formula from Example 3-8, $R = \frac{v_0^2 \sin 2\theta_0}{r}$. The $0^{0.0111}$ ω_0 The $v_0^2 \sin 2\theta_0$ $R = \frac{r_0 \sin 2\theta_0}{r}$. The *g* . The

maximum height of the projectile will occur when its vertical speed is 0. Apply Eq. 2-11c.

$$
v_y^2 = v_{y0}^2 + 2a_y (y - y_0)
$$
 \rightarrow $0 = v_0^2 \sin^2 \theta_0 - 2gy_{\text{max}}$ \rightarrow $y_{\text{max}} = \frac{v_0^2 \sin^2 \theta_0}{2g}$

Now find the angle for which $R = y_{\text{max}}$. y_{max} .

$$
R = y_{\text{max}} \rightarrow \frac{v_0^2 \sin 2\theta_0}{g} = \frac{v_0^2 \sin^2 \theta_0}{2g} \rightarrow \sin 2\theta_0 = \frac{\sin^2 \theta_0}{2} \rightarrow
$$

$$
2 \sin \theta_0 \cos \theta_0 = \frac{\sin^2 \theta_0}{2} \rightarrow 4 \cos \theta_0 = \sin \theta_0 \rightarrow \tan \theta_0 = 4 \rightarrow \theta_0 = \tan^{-1} 4 = 76^\circ
$$

34. Choose the origin to be the location from which the balloon is fired, and choose upward as the positive *y* direction. Assume the boy in the tree is a distance H up from the point at which the balloon is fired, and that the tree is a distance *D* horizontally from the point at which the balloon is fired. The equations of \overline{D} motion for the balloon and boy are as follows, using constant acceleration relationships.

$$
x_{\text{Balloon}} = v_0 \cos \theta_0 t
$$
 $y_{\text{Balloon}} = 0 + v_0 \sin \theta_0 t - \frac{1}{2}gt^2$ $y_{\text{Boy}} = H - \frac{1}{2}gt^2$

Use the horizontal motion at constant velocity to find the elapsed time after the balloon has traveled *D* to the right.
 $D = v_0 \cos \theta_0 t_D \rightarrow t_D = \frac{D}{v_0}$

$$
D = v_0 \cos \theta_0 t_D \qquad \rightarrow \qquad t_D = \frac{D}{v_0 \cos \theta_0}
$$

Where is the balloon vertically at that time?

$$
y_{\text{Balloon}} = v_0 \sin \theta_0 t_D - \frac{1}{2} g t_D^2 = v_0 \sin \theta_0 \frac{D}{v_0 \cos \theta_0} - \frac{1}{2} g \left(\frac{D}{v_0 \cos \theta_0} \right)^2 = D \tan \theta_0 - \frac{1}{2} g \left(\frac{D}{v_0 \cos \theta_0} \right)^2
$$

Where is the boy vertically at that time? Note that $H = D \tan \theta$. . A construction of the construction of th

$$
y_{\text{Boy}} = H - \frac{1}{2}gt_D^2 = H - \frac{1}{2}g\left(\frac{D}{v_0 \cos \theta_0}\right)^2 = D \tan \theta_0 - \frac{1}{2}g\left(\frac{D}{v_0 \cos \theta_0}\right)^2
$$

The boy and the balloon are at the same height and the same horizontal location at the same time. Thus they collide!

35. Choose the origin to be the location on the ground directly below the airplane at the time the supplies are dropped, and choose upward as the positive *y* direction. For the supplies, $y_0 = 235$ m, $v_{y0} = 0$, $y_0 = 235 \text{ m}$, $v_{y0} = 0$, $v_{y0} = 0,$ $v_{v0} = 0$,

 $a_y = -g$, and the final *y* location is $y = 0$ m. The initial (and constant) *x* velocity of the supplies is $x = 69.4 \text{ m/s}.$ $v_r = 69.4 \text{ m/s}.$

(*a*) The time for the supplies to reach the ground is found from Eq. 2-11b.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \rightarrow 0 = y_0 + 0 + \frac{1}{2}at^2 \rightarrow t = \sqrt{\frac{-2y_0}{a}} = \sqrt{\frac{-2(235 \text{ m})}{(-9.80 \text{ m/s}^2)}} = 6.93 \text{ s}
$$

Then the horizontal distance of travel for the package is found from the horizontal motion at constant velocity.

 $\Delta x = v_t = (69.4 \text{ m/s})(6.93 \text{ s}) = |481 \text{ m}|$ $t = (69.4 \text{ m/s})(6.93 \text{ s}) = 481 \text{ m}$

(*b*) Now the supplies have to travel a horizontal distance of only 425 m. Thus the time of flight will be less, and is found from the horizontal motion at constant velocity.

$$
\Delta x = v_x t \rightarrow t = \Delta x / v_x = 425 \text{ m} / 69.4 \text{ m} / \text{s} = 6.124 \text{ s}.
$$

The *y* motion must satisfy Eq. 2-11b for this new time, but the same vertical displacement and acceleration.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \rightarrow
$$

\n
$$
v_{y0} = \frac{y - y_0 - \frac{1}{2}a_yt^2}{t} = \frac{0 - 235 \text{ m} - \frac{1}{2}(-9.80 \text{ m/s}^2)(6.124 \text{ s})^2}{6.124 \text{ s}} = \frac{-8.37 \text{ m/s}}{0.124 \text{ s}}
$$

Notice that since this is a negative velocity, the object must be projected DOWN.
(*c*) The horizontal component of the speed of the supplies upon landing is the constant horizontal speed of 69.4 m/s. The vertical speed is found from Eq. 2-11a.

$$
v_y = v_{y0} + a_y t = -8.37 \text{ m/s} + (-9.80 \text{ m/s}^2)(6.124 \text{ s}) = 68.4 \text{ m/s}
$$

Thus the speed is given by Thus the speed is given by

$$
v = \sqrt{v_x^2 + v_y^2} = \sqrt{(69.4 \text{ m/s})^2 + (68.4 \text{ m/s})^2} = 97.4 \text{ m/s}
$$

36. Call the direction of the boat relative to the water the positive direction.

(a)
$$
\vec{v}_{\text{jogger}} = \vec{v}_{\text{jogger}} + \vec{v}_{\text{boat rel. boat}} = 2.2 \text{ m/s} + 7.5 \text{ m/s}
$$

\n
$$
= \boxed{9.7 \text{ m/s in the direction the boat is moving}}
$$
\n(b) $\vec{v}_{\text{jogger}} = \vec{v}_{\text{jogger}} + \vec{v}_{\text{boat rel.}} = -2.2 \text{ m/s} + 7.5 \text{ m/s}$ \n
$$
= \boxed{5.3 \text{ m/s in the direction the boat is moving}} = \boxed{5.3 \text{ m/s in the direction the boat is moving}}
$$

37. Call the direction of the flow of the river the *x* direction, and the direction of Huck walking relative to the raft the *y* direction.

$$
\vec{v}_{Huck} = \vec{v}_{Huck} + \vec{v}_{raff rel. left} - (0, 0.6) m/s + (1.7, 0) m/s
$$
\n
$$
= (1.7, 0.6) m/s
$$
\n
$$
= (1.7, 0.6) m/s
$$
\n
$$
\vec{v}_{Huck} = \sqrt{1.7^2 + 0.6^2} = 1.8 m/s
$$
\n
$$
\vec{v}_{Huck} = \sqrt{1.7^2 + 0.6^2} = 1.8 m/s
$$
\n
$$
\vec{v}_{raff} = \vec{v}_{raff}
$$
\n
$$
\vec{
$$

38. We have $v_{\text{car rel.}} = 25 \text{ m/s}$. Use the diagram, illustrating $\vec{v}_{\text{snow rel.}} = \vec{v}_{\text{snow rel.}} + \vec{v}_{\text{car rel.}}$, to calculate the ground $\vec{v}_{\text{snow rel}} = \vec{v}_{\text{snow rel}} + \vec{v}_{\text{car rel}}$, to calculate the other speeds.

39. Call the direction of the flow of the river the *x* direction, and the direction the $\vec{v}_{\text{water rel.}}$ boat is headed the *y* direction.

(*b*) The position of the boat after 3.00 seconds is given by

$$
\Delta d = v_{\text{bater}} t = [(1.20, 2.30) \text{ m/s}](3.00 \text{ sec})
$$

$$
= \boxed{(3.60 \text{ m downstream}, 6.90 \text{ m across the river})}
$$

As a magnitude and direction, it would be 7.8 m away from the starting point, at an angle of 62.4° relative to the shore. 62.4° relative to the shore.

40. If each plane has a speed of 785 km/hr, then their relative speed of approach is 1570 km/hr. If the planes are 11 km apart, then the time for evasive action is found from

$$
\Delta d = vt \quad \rightarrow \quad t = \frac{\Delta d}{v} = \left(\frac{11.0 \text{ km}}{1570 \text{ km/hr}}\right) \left(\frac{3600 \text{ sec}}{1 \text{ hr}}\right) = 25.2 \text{ s}
$$

41. Call east the positive *x* direction and north the positive *y* direction. Then the following vector velocity relationship exists.

(a)
$$
\vec{v}_{plane \text{ rel. air}} = \vec{v}_{plane} + \vec{v}_{airrel.}
$$

\n
$$
= (0, -600) \text{ km/h} + (100 \cos 45.0^{\circ}, 100 \sin 45.0^{\circ}) \text{ km/h}

$$
+ (1.50, 0) \text{ m/s} = (1.854, 0.354) \text{ m/s}
$$
\n
$$
v_{\text{passenger}} = \sqrt{1.854^2 + 0.354^2} = 1.89 \text{ m/s}
$$
\n
$$
v_{\text{passenger}} = \sqrt{1.854^2 + 0.354^2} = 1.89 \text{ m/s}
$$

45. Call the direction of the flow of the river the *x* direction, and the direction $\vec{v}_{\text{water rel}}$ straight across the river the *y* direction. The boat is traveling straight across the river. The boat is headed at $\theta = 28.5^{\circ}$ upstream, at a speed of ver. The boat is headed at $\theta = 28.5^{\circ}$ upstream, at a speed of
boat rel. = 2.60 m/s.

$$
v_{\text{boat rel.}} = 2.60 \,\text{m/s}
$$

(a)
$$
\sin \theta = v_{\text{water rel.}} / v_{\text{boat rel.}} \rightarrow v_{\text{water rel.}} = (2.60 \text{ m/s}) \sin 28.5^\circ = 1.24 \text{ m/s}
$$

\n(b) $\cos \theta = v_{\text{boat rel.}} / v_{\text{boat rel.}} \rightarrow v_{\text{boat rel.}} = (2.60 \text{ m/s}) \cos 28.5^\circ = 2.28 \text{ m/s}$

46. Call the direction of the flow of the river the *x* direction, and the $\vec{v}_{\text{water rel}}$ direction straight across the river the *y* direction. From the diagram, \vec{r} or \vec{r} or $\theta = \tan^{-1} 110 \text{ m}/260 \text{ m} = 22.9^\circ$. Equate the vertical components of the $\theta = \tan^{-1} 110 \text{ m}/260 \text{ m} = 22.9^{\circ}$. Equate the vertical components of the velocities to find the speed of the boat relative to the shore. 260 m

$$
v_{\text{boat rel.}} \cos \theta = v_{\text{boat rel.}} \sin 45^{\circ} \rightarrow
$$

\n
$$
v_{\text{boat rel.}} = (1.70 \text{ m/s}) \frac{\sin 45^{\circ}}{\cos 22.9^{\circ}} = 1.305 \text{ m/s}
$$

Equate the horizontal components of the velocities.

$$
v_{\text{boat rel.}} \sin \theta = v_{\text{boat rel.}} \cos 45^{\circ} - v_{\text{water}} \rightarrow
$$

\n
$$
v_{\text{water}} = v_{\text{boat rel.}} \cos 45^{\circ} - v_{\text{boat rel.}} \sin \theta
$$

\n
$$
v_{\text{water}} = (1.70 \text{ m/s}) \cos 45^{\circ} - (1.305 \text{ m/s}) \sin 22.9^{\circ} = 0.69 \text{ m/s}
$$

47. Call the direction of the flow of the river the *x* direction, and the direction $\vec{v}_{\text{water rel}}$ straight across the river the *y* direction. Call the location of the swimmer's starting point the origin.

(*a*) Since the swimmer starts from the origin, the distances covered in the *x* and *y* directions will be exactly proportional to the speeds in those directions.

$$
\frac{\Delta x}{\Delta y} = \frac{v_x t}{v_y t} = \frac{v_x}{v_y} \quad \rightarrow \quad \frac{\Delta x}{75 \text{ m}} = \frac{0.40 \text{ m/s}}{0.45 \text{ m/s}} \quad \rightarrow \quad \Delta x = \boxed{67 \text{ m}}
$$

(*b*) The time is found from the constant velocity relationship for either the *x* or *y* directions.

$$
\Delta y = v_y t \rightarrow t = \frac{\Delta y}{v_y} = \frac{75 \text{ m}}{0.45 \text{ m/s}} = 170 \text{ s}
$$

48. (*a*) Call the direction of the flow of the river the *x* direction, and the direction straight across the river the *v* direction. direction straight across the river the *y* direction.

$$
\sin \theta = \frac{v_{\text{water rel.}}}{v_{\text{swimmer}}} = \frac{0.40 \text{ m/s}}{0.45 \text{ m/s}} \rightarrow \theta = \sin^{-1} \frac{0.40}{0.45} = 62.73^{\circ} = 62^{\circ}
$$
\n
$$
\cos \theta = \frac{v_{\text{water rel.}}}{v_{\text{eximmer}}}
$$
\n
$$
\vec{v}_{\text{swimmer}} = \frac{v_{\text{water rel.}}}{v_{\text{rel. shorter}}}
$$

 (b) From the diagram her speed with respect to the shore is

$$
v_{\text{swimmer}} = v_{\text{swimmer}} \cos \theta = (0.45 \text{ m/s}) \cos 62.73^{\circ} = 0.206 \text{ m/s}
$$

The time to cross the river can be found from the constant velocity relationship.

$$
\Delta x = vt \rightarrow t = \frac{\Delta x}{v} = \frac{75 \text{ m}}{0.206 \text{ m/s}} = 364 \text{ s} = \boxed{3.6 \times 10^2 \text{ s} = 6.1 \text{ min}}
$$

49. Call east the positive *x* direction and north the positive *y* direction. The following is seen from the diagram. Apply the law of sines to the triangle \mathbb{Z} formed by the three vectors.

$$
\frac{v_{\text{plane}}}{\sin 125^\circ} = \frac{v_{\text{air rel.}}}{\sin \theta} \rightarrow \sin \theta = \frac{v_{\text{air rel.}}}{v_{\text{plane}}}
$$
\n
$$
\theta = \sin^{-1} \left(\frac{95}{620} \sin 125^\circ \right) = 7.211^\circ
$$
\n
$$
\theta = \frac{95}{620} \sin 125^\circ = 7.211^\circ
$$

swimmer

 \vec{v}_{swimmer} rel. shore

So the plane should head in a direction of $35.0^{\circ} + 7.2^{\circ} = 42.2^{\circ}$ north of east.

50. Take the origin to be the location at which the speeder passes the police car, in the reference frame of the unaccelerated police car. The speeder is traveling at $145 \text{ km/h} \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) = 40.28 \text{ m/s}$ 1 m/s \qquad 145 km/h $\frac{1 \text{ m/s}}{2 \text{ m/s}}$ $= 40.28 \text{ m/s}$ 3.6 km/h \prime 1 m/s $26.29 \text{ J} \cdot \text{m}$ *that the condition* $\frac{V_{\text{gauge}}}{V_{\text{gauge}}}$ $\frac{V_{\text{gauge}}}{V_{\text{gauge}}}$
 $\theta = \sin^{-1}\left(\frac{95}{620}\sin 125^\circ\right) = 7.211^\circ$
 $\theta = \frac{V_{\text{gauge}}}{V_{\text{gauge}}}$
 $\theta = \sin^{-1}\left(\frac{95}{620}\sin 125^\circ\right) = 7.211^\circ$
 $\theta = \frac{V_{\text{gauge}}}{V_{\text{gauge}}}$
 $\theta = \sin^{-1}\left(\frac{95$

relative to the ground, and the policeman is traveling at 95 km/h $\frac{100}{25}$ = 26.39 m/s relative 3.6 km/h / relative

to the ground. Relative to the unaccelerated police car, the speeder is traveling at $13.89 \text{ m/s} = v_s$, and the police car is not moving. Do all of the calculations in the frame of reference of the unaccelerated police car.

The position of the speeder in the chosen reference frame is given by $\Delta x = v_t t$. The position of the policeman in the chosen reference frame is given by $\Delta x_p = \frac{1}{2} a_p (t-1)^2$, $t > 1$. The police car overtakes the speeder when these two distances are the same.; i.e., $\Delta x_s = \Delta x_p$. $x_{s} = \Delta x_{n}$.

$$
\Delta x_s = \Delta x_p \rightarrow v_s t = \frac{1}{2} a_p (t-1)^2 \rightarrow (13.89 \text{ m/s}) t = \frac{1}{2} (2 \text{ m/s}^2) (t^2 - 2t + 1) = t^2 - 2t + 1
$$

$$
t^2 - 15.89t + 1 = 0 \rightarrow t = \frac{15.89 \pm \sqrt{15.89^2 - 4}}{2} = 0.0632 \text{ s}, 15.83 \text{ s}
$$

Since the police car doesn't accelerate until $t = 1.00$ s, the correct answer is $t = 15.8$ s.

51. Take the origin to be the location at which the speeder passes the police car. The speed of the speeder is v_s . The position of the speeder after the 7.00 seconds is $\Delta x_s = v_s t = v_s (7.00 \text{ s})$. The position of the police car is calculated based on the fact that the car traveled 1 second at the original velocity, and then 6 seconds under acceleration. Note that the police car's velocity must have the units changed.

$$
v_p = (95 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) = 26.39 \text{ m/s}
$$
 $a_p = 2.00 \text{ m/s}^2$

$$
\Delta x_p = v_p (1.00 \text{ s}) + v_p (6.00 \text{ s}) + \frac{1}{2} a_p (6.00 \text{ s})^2 = 220.7 \text{ m}
$$

The police car overtakes the speeder when these two distances are the same; i.e., $\Delta x_s = \Delta x_p$. $x_{\rm s} = \Delta x_{\rm n}$.

$$
v_s(7 \text{ s}) = 220.7 \text{ m} \rightarrow v_s = \frac{220.7 \text{ m}}{7 \text{ s}} \left(\frac{3.6 \text{ km/h}}{1 \text{ m/s}} \right) = \boxed{114 \text{ km/h}}
$$

52. Call east the positive *x* direction and north the positive *y* direction. From $\vec{v}_{\text{car 2 rel}}$ the first diagram, this relative velocity relationship is seen.

$$
\vec{v}_{\text{car 1 rel.}} = \vec{v}_{\text{car 1 rel.}} + \vec{v}_{\text{car 2 rel.}} \rightarrow v_{\text{car 1 rel.}} = \sqrt{(-55)^2 + (35)^2} = \boxed{65 \text{ km/h}}
$$
\n
$$
\vec{v}_{\text{car 1 rel.}} = \sqrt{(-55)^2 + (35)^2} = \boxed{65 \text{ km/h}}
$$
\n
$$
\vec{v}_{\text{car 1 rel.}} = \sqrt{(-55)^2 + (35)^2} = \boxed{65 \text{ km/h}}
$$
\n
$$
\vec{v}_{\text{car 1 rel.}} = \sqrt{(-55)^2 + (35)^2} = \boxed{65 \text{ km/h}}
$$
\n
$$
\vec{v}_{\text{car 2 rel.}} = \sqrt{(-55)^2 + (35)^2} = \boxed{65 \text{ km/h}}
$$
\n
$$
\vec{v}_{\text{car 2 rel.}} = \sqrt{(-55)^2 + (35)^2} = \boxed{65 \text{ km/h}}
$$
\n
$$
\vec{v}_{\text{car 2 rel.}} = \sqrt{(-55)^2 + (35)^2} = \boxed{65 \text{ km/h}}
$$
\n
$$
\vec{v}_{\text{car 2 rel.}} = \sqrt{(-55)^2 + (35)^2} = \boxed{65 \text{ km/h}}
$$
\n
$$
\vec{v}_{\text{car 2 rel.}} = \sqrt{(-55)^2 + (35)^2} = \boxed{65 \text{ km/h}}
$$

 1 and 1 and 1 and 1 and 1 and 1 and 1 *^x d*

 \int_{xy}^{x} \int_{y}^{u}

^y d

For the other relative velocity relationship: $V_{\text{car 2 rel.}}$

$$
\mathbf{v}_{\text{start}} = \mathbf{v}_{\text{car 1}} - \mathbf{v}_{\text{car 2}} = \mathbf{v}_{\text{start}} + \mathbf{v}_{\text{ear 2}} - \mathbf{v}_{\text{start}} - \mathbf{v}_{\text{car 2}} = \mathbf{v}_{\text{start}} - \mathbf{v}_{\text
$$

Notice that the two relative velocities are opposites of each other: $\vec{v}_{car 2 rel.} = -\vec{v}_{car 1 rel.}$ $\operatorname{car} 1$ car 2 $\vec{\mathbf{v}}_{\text{car 2 rel}}^{\dagger} = -\vec{\mathbf{v}}_{\text{car 1 rel}}^{\dagger}$

53. Since the arrow will start and end at the same height, use the range formula derived in Example 3-8. The range is 27 m, and the initial speed of the arrow is 35 m/s.

$$
R = \frac{v_0^2 \sin 2\theta_0}{g} \rightarrow \sin 2\theta_0 = \frac{Rg}{v_0^2} = \frac{(27 \text{ m})(9.80 \text{ m/s}^2)}{(35 \text{ m/s})^2} = 0.216
$$

$$
\theta_0 = \frac{1}{2} \sin^{-1} 0.216 = 6.2^\circ, 83.8^\circ
$$
the first answer is practical, so the result is $\theta_0 = 6.2^\circ$.

Only the first answer is practical, so the result is $\vert \theta_0 = 6.2^\circ \vert$. 0° - 0.2 | \cdot

54. The plumber's displacement in component notation is

 $\vec{\mathbf{d}} = (50 \text{ m}, -25 \text{ m}, -10 \text{ m})$. Since this is a 3-dimensional problem, it

requires 2 angles to determine his location (similar to latitude and longitude on the surface of the Earth). In the *x*-*y* plane, this follows.

$$
\theta_1 = \tan^{-1} \frac{d_y}{d_x} = \tan^{-1} \frac{25}{50} = 27^{\circ}
$$
 South of East

$$
d_{xy} = \sqrt{d_x^2 + d_y^2} = \sqrt{(50)^2 + (-25)^2} = 55.9 \text{ m}
$$

For the vertical motion, consider another right triangle, made up of d_{y} as one leg, and the vertical displacement d_z as the other leg. See the second figure, and the following calculations.

$$
\theta_2 = \tan^{-1} \frac{d_z}{d_{xy}} = \tan^{-1} \frac{10 \text{ m}}{55.9 \text{ m}} = 10^{\circ} \text{ Below the Horizontal}
$$

$$
d = \sqrt{d_{xy}^2 + d_z^2} = \sqrt{d_x^2 + d_y^2 + d_z^2} = \sqrt{(50)^2 + (-25)^2 + (-10)^2} = 57 \text{ m}
$$

The result is that the displacement is $\left[57 \text{ m}\right]$, at an angle of $\left[27^{\circ}$ South of East, and $\left[10^{\circ}$ Belay the Uguinantal 10° Below the Horizontal.

55. Assume a constant upward slope, and so the deceleration is along a straight line. The starting velocity along that line is $120 \text{ km/h} \left(\frac{1 \text{ m/s}}{1 \text{ m/s}} \right) = 33.3 \text{ m/s}$. The ending velocity is 0 m/s. The 3.6 km h . The ending velocity is 0 m/s. The acceleration is found from Eq. 2-11a.

$$
v = v_0 + at \rightarrow 0 = 33.3 \text{ m/s} + a (6.0 \text{ s}) \rightarrow a = -\frac{33.3 \text{ m/s}}{6.0 \text{ s}} = -5.56 \text{ m/s}^2
$$

The horizontal acceleration is $a_{\text{horiz}} = a \cos \theta = -5.56 \text{ m/s}^2 (\cos 32^\circ) = -4.7 \text{ m/s}^2$.
The vertical acceleration is $a_{\text{vert}} = a \sin \theta = -5.56 \text{ m/s}^2 (\sin 30^\circ) = -2.8 \text{ m/s}^2$

The horizontal acceleration is to the left in the textbook diagram, and the vertical acceleration is down.

56. Magnitude = $\sqrt{75.4^2 + y^2}$ = 88.5 \rightarrow $y = \pm \sqrt{88.5^2 - 75.4^2}$ = ± 46.34 = $\sqrt{\pm 46.3}$ Direction = $\tan^{-1} \frac{46.34}{\pi} = 31.6^{\circ}$ relative to x axis $\overline{75.4}$ x axis 75.4 88.5 88.5 \rightarrow

See the diagram for the two possible answers.

57. Choose the *x* direction to be the direction of train travel (the direction the passenger is facing) and choose the *y* direction to be up. This relationship exists \vec{v}_{min} ϕ \vec{v}_{min} \vec{v}_{min} among the velocities: $\vec{v}_{\text{rain rel.}} = \vec{v}_{\text{rain rel.}} + \vec{v}_{\text{rain rel.}}$ From the diagram, find the \vec{v}_{train} rain rel. $\vec{v}_{\text{train rel}} = \vec{v}_{\text{train rel}} + \vec{v}_{\text{train rel}}$. From the diagram, find the

expression for the speed of the raindrops.

$$
\tan \theta = \frac{v_{\text{train rel.}}}{v_{\text{rain rel.}}}
$$
\n
$$
\theta = \frac{v_{\text{T}}}{v_{\text{rain rel.}}}
$$
\n
$$
\frac{v_{\text{train rel.}}}{v_{\text{rain rel.}}}
$$
\n
$$
\frac{v_{\text{train rel.}}}{v_{\text{ground}}}
$$

58. Call east the positive *x* direction and north the positive *y* direction. Then this relative velocity relationship follows (see the accompanying diagram).
 $\vec{v}_{\text{plane}} \left\| \text{A5}^{\text{plane}} \right\|$

$$
\vec{v}_{\text{plane rel. air}} = \vec{v}_{\text{plane}} + \vec{v}_{\text{air rel. air}}
$$

Equate the *x* components of the velocity vectors.

$$
(125 \text{ km/h}) \cos 45^\circ = 0 + v_{\text{wind}x} \rightarrow v_{\text{wind}x} = 88.4 \text{ km/h}.
$$

From the *y* components of the above equation:

$$
-125\sin 45^{\circ} = -155 + v_{\text{wind-y}} \quad \rightarrow \quad v_{\text{wind-y}} = 155 - 125\sin 45^{\circ} = 66.6 \text{ km/h}
$$

The magnitude of the wind velocity is
\n
$$
v_{\text{wind}} = \sqrt{v_{\text{wind-x}}^2 + v_{\text{wind-y}}^2} = \sqrt{(88.4 \text{ km/h})^2 + (66.6 \text{ km/h})^2} = 111 \text{ km/h}.
$$

The direction of the wind is $\theta = \tan^{-1} \frac{v_{\text{wind-y}}}{\sqrt{v_{\text{wind-y}}}} = \tan^{-1} \frac{0.000}{\sqrt{v_{\text{wind}}}} = 37.0^{\circ}$ north of east. $\bigcup_{\mathbf{W} \in \mathcal{X}} \mathbf{W}$ $\tan^{-1} \frac{v_{\text{wind-y}}}{v_{\text{wind-y}}} = \tan^{-1} \frac{66.6}{v_{\text{dot}}} = 37.0^{\circ}$ north of east. 88.4 **Francisco Executive Contract Contrac** $v_{\text{wind-v}}$ $1.66.6$ \overline{z} \over $v_{\text{wind-x}}$ 88.4 .

59. Work in the frame of reference in which the train is at rest. Then, relative to the train, the car is moving at 20 km/h. The car has to travel 1 km in that frame of reference to pass the train, and so the time to pass can be found from the constant horizontal velocity relationship.

$$
\Delta x = v_x t \quad \rightarrow \quad t_{\text{same}} = \frac{\Delta x}{(v_x)_{\text{same}}} = \frac{1 \text{ km}}{20 \text{ km/h}} = 0.05 \text{ h} \left(\frac{3600 \text{ s}}{1 \text{ h}}\right) = 180 \text{ s}
$$

The car travels 1 km in the frame of reference of the stationary train, but relative to the ground, the car is traveling at 95 km/hr and so relative to the ground the car travels this distance:

$$
\Delta x = v_x t_{\text{same}} = (95 \text{ km/h})(0.05 \text{ h}) = 4.8 \text{ km}
$$

If the car and train are traveling in opposite directions, then the velocity of the car relative to the train will be 170 km/h. Thus the time to pass will be

$$
t_{\text{opposite}\atop{\text{direction}}} = \frac{\Delta x}{\left(v_x\right)_{\text{opposite}\atop{\text{direction}}}} = \frac{1 \text{ km}}{170 \text{ km/h}} = \left(\frac{1}{170} \text{ h}\right) \left(\frac{3600 \text{ s}}{1 \text{ h}}\right) = \boxed{21.2 \text{ s}}.
$$

The distance traveled by the car relative to the ground will be

$$
\Delta x = v_x t_{\text{opposite}} = (95 \text{ km/h}) \left(\frac{1}{170} \text{ h} \right) = 0.56 \text{ km}.
$$

60. The time of flight is found from the constant velocity relationship for horizontal motion.

$$
\Delta x = v_x t = \rightarrow t = \Delta x / v_x = 8.0 \text{ m} / 9.1 \text{ m/s} = 0.88 \text{ s}
$$

The *y* motion is symmetric in time – it takes half the time of flight to rise, and half to fall. Thus the time for the jumper to fall from his highest point to the ground is 0.44 sec. His vertical speed is zero at the highest point. From this time, starting vertical speed, and the acceleration of gravity, the maximum height can be found. Call upward the positive *y* direction. The point of maximum height is the starting position y_0 , the ending position is $y = 0$, the starting vertical speed is 0, and $a = -g$.
Use Eq. 2-11b to find the height.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \rightarrow 0 = y_0 + 0 - \frac{1}{2}(9.8 \text{ m/s}^2)(0.44 \text{ s})^2 \rightarrow y_0 = 0.95 \text{ m}.
$$

61. Assume that the golf ball takes off and lands at the same height, so that the range formula derived in Example 3-8 can be applied. The only variable is to be the acceleration due to gravity.

$$
R_{\text{Earth}} = v_0^2 \sin 2\theta_0 / g_{\text{Earth}}
$$

\n
$$
R_{\text{Rath}} = \frac{v_0^2 \sin 2\theta_0 / g_{\text{Earth}}}{v_0^2 \sin 2\theta_0 / g_{\text{Earth}}} = \frac{1/g_{\text{Earth}}}{1/g_{\text{Moon}}} = \frac{g_{\text{Moon}}}{g_{\text{Earth}}} = \frac{35 \text{ m}}{180 \text{ m}} = 0.19 \rightarrow g_{\text{Moon}} = 0.19 g_{\text{Earth}} \approx \boxed{1.9 \text{ m/s}^2}
$$

62. The minimum speed will be that for which the ball just clears the fence; i.e., the ball has a height of 7.5 m when it is 95 m horizontally from home plate. The origin is at home plate, with upward as the positive *y* direction. For the ball, $y_0 = 1.0$ m, $y = 7.5$ m, $a_y = -g$,

(not to scale). For the horizontal motion at constant velocity,
$$
\Delta x = 95 \text{ m}
$$

\n
$$
\Delta x = v_x t = v_0 \cos \theta_0 t \text{, and so } t = \frac{\Delta x}{v_0 \cos \theta_0}. \text{ For the vertical motion, apply Eq. 2-11b.}
$$
\n
$$
y = y_0 + v_{y0} t + \frac{1}{2} a_y t^2 = y_0 + v_0 (\sin \theta_0) t - \frac{1}{2} g t^2
$$

Substitute the value of the time of flight for the first occurrence only in the above equation, and then solve for the time.

$$
y = y_0 + v_0 t \sin \theta_0 - \frac{1}{2}gt^2 \rightarrow y = y_0 + v_0 \sin \theta_0 \frac{\Delta x}{v_0 \cos \theta_0} - \frac{1}{2}gt^2 \rightarrow t = \sqrt{2\left(\frac{y_0 - y + \Delta x \tan \theta_0}{g}\right)} = \sqrt{2\left(\frac{1.0 \text{ m} - 7.5 \text{ m} + (95 \text{ m}) \tan 38^\circ}{9.80 \text{ m/s}^2}\right)} = 3.718 \text{ s}
$$

Finally, use the time with the horizontal range to find the initial speed.

$$
\Delta x = v_0 \cos \theta_0 t \rightarrow v_0 = \frac{\Delta x}{t \cos \theta_0} = \frac{95 \text{ m}}{(3.718 \text{ s}) \cos 38^\circ} = 32 \text{ m/s}
$$

63. Choose downward to be the positive *y* direction. The origin is at the point from which the divers push off the cliff. In the vertical direction, the initial velocity is $v_{y0} = 0$, the acceleration is $v_{y0} = 0.80 \text{ m/s}^2$, and the displacement is 25 m. The time of flight is found from Eq. 2.11b $y_0 = 0$, the acceleration is

 $a_y = 9.80 \text{ m/s}^2$, and the displacement is 35 m. The time of flight is found from Eq. 2-11b.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \quad \rightarrow \quad 35 \text{ m} = 0 + 0 + \frac{1}{2}(9.8 \text{ m/s}^2)t^2 \quad \rightarrow \quad t = \sqrt{\frac{2(35 \text{ m})}{9.8 \text{ m/s}^2}} = \boxed{2.7 \text{ s}}
$$

The horizontal speed (which is the initial speed) is found from the horizontal motion at constant velocity.

$$
\Delta x = v_x t \quad \rightarrow \quad v_x = \Delta x / t = 5.0 \text{ m} / 2.7 \text{ s} = \boxed{1.9 \text{ m} / \text{s}}
$$

64. Choose the origin to be the location on the ground directly underneath the ball when served, and choose upward as the positive *y* direction. Then for the ball, $y_0 = 2.50$ m, $v_{y0} = 0$, $a_y = -g$, and $y_0 = 2.50$ m, $v_{y0} = 0$, $a_y = -g$, and $_{y_0} = 0$, $a_y = -g$, and $v_{y0} = 0$, $a_y = -g$, and the *y* location when the ball just clears the net is $y = 0.90$ m. The time for the ball to reach the net is calculated from Eq. 2-11b.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \rightarrow 0.90 \text{ m} = 2.50 \text{ m} + 0 + \frac{1}{2}(-9.80 \text{ m/s}^2)t^2 \rightarrow
$$

$$
t_{\text{to}} = \sqrt{\frac{2(-1.60 \text{ m})}{-9.80 \text{ m/s}^2}} = 0.57143 \text{ s}
$$

The *x* velocity is found from the horizontal motion at constant velocity.

$$
\Delta x = v_x t \rightarrow v_x = \frac{\Delta x}{t} = \frac{15.0 \text{ m}}{0.57143 \text{ s}} = 26.25 \approx 26.3 \text{ m/s}.
$$

This is the minimum speed required to clear the net.

To find the full time of flight of the ball, set the final *y* location to be $y = 0$, and again use Eq. 2-11b. $y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \rightarrow 0.0 \text{ m} = 2.50 \text{ m} + \frac{1}{2}(-9.80 \text{ m/s}^2)t^2 \rightarrow$

$$
t_{\text{total}} = \sqrt{\frac{2(-2.50 \text{ m})}{-9.80 \text{ m/s}^2}} = 0.7143 \approx \boxed{0.714 \text{ s}}
$$

The horizontal position where the ball lands is found from the horizontal motion at constant velocity. $x = v_x t = (26.25 \text{ m/s})(0.7143 \text{ s}) = 18.75 \approx 18.8 \text{ m}.$

Since this is between 15.0 and 22.0 m, $\boxed{\text{the ball lands in the "good" region}}$.

65. Work in the frame of reference in which the car is at rest at ground level. In this reference frame, the helicopter is moving horizontally with a speed of

$$
215 \text{ km/h} - 155 \text{ km/h} = 60 \text{ km/h} \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) = 16.67 \text{ m/s} \,.
$$

. For the vertical motion, choose the level of the helicopter to be the origin, and downward to be positive. Then the package's *y* displacement is $y = 78.0$ m, $v_{y0} = 0$, and $a_y = g$. The time for the package to fall is calculated from Eq. 2-11b.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \quad \rightarrow \quad 78.0 \text{ m} = \frac{1}{2}(9.80 \text{ m/s}^2)t^2 \quad \rightarrow \quad t = \sqrt{\frac{2(78.0 \text{ m})}{9.80 \text{ m/s}^2}} = 3.99 \text{ sec}
$$

The horizontal distance that the package must move, relative to the "stationary" car, is found from the horizontal motion at constant velocity.

$$
\Delta x = v_x t = (16.67 \text{ m/s})(3.99 \text{ s}) = 66.5 \text{ m}
$$

Thus the angle under the horizontal for the package release will be
\n
$$
\theta = \tan^{-1} \left(\frac{\Delta y}{\Delta x} \right) = \tan^{-1} \left(\frac{78.0 \text{ m}}{66.5 \text{ m}} \right) = 49.55^{\circ} \approx 50^{\circ}
$$
 (to 2 significant figures).

66. (*a*) For the upstream trip, the boat will cover a distance of $D/2$ with a net speed of $v - u$, so the time is $t_1 = \frac{D/2}{2} = \frac{D}{2(1-\lambda)}$. For the downstream trip, the boat will cover a distance of $D/2$ $2(v-u)$ $t_1 = \frac{D/2}{D} = \frac{D}{D}$. For the downstream trip, the boat will cover a distance of $D/2$ $v - u \quad 2(v - u)$. For the downstream trip, the boat will cover a distance of $D/2$

with a net speed of $v+u$, so the time is $t_2 = \frac{D/2}{2} = \frac{D}{2(2\pi)^2}$. Thus the total time for the $2(v+u)$ $t_2 = \frac{D/2}{D} = \frac{D}{D}$. Thus the total time for the $v + u \quad 2(v + u)$. Thus the total time for the

round trip will be
$$
t = t_1 + t_2 = \frac{D}{2(v - u)} + \frac{D}{2(v + u)} = \boxed{\frac{Dv}{(v^2 - u^2)}}
$$
.

(*b*) For the boat to go directly across the river, it must be angled against $\vec{v}_{water rel.} = \vec{u}$ the current in such a way that the net velocity is straight across the shore

For the boat to go directly across the river, it must be angled against
\nthe current in such a way that the net velocity is straight across the
\nriver, as in the picture. This equation must be satisfied:
\n
$$
\vec{v}_{\text{boat rel.}} = \vec{v} + \vec{u}
$$
\n
$$
\vec{v}_{\text{boat rel.}} = \vec{v} + \vec{u}
$$
\nThus $v_{\text{water}} = \sqrt{v^2 - u^2}$, and the time to go a distance $D/2$ across
\n $v_{\text{water}} = \vec{v}$

the river is $t_1 = \frac{2t^2}{\sqrt{a^2 + 2t^2}} = \frac{2t^2}{2\sqrt{a^2 + 2t^2}}$. The same relationship would be in effect for crossing 2 D \mathbb{R} \mathbb{R} $2\sqrt{v^2-u^2}$ $t_1 = \frac{D/2}{\sqrt{D}} = \frac{D}{\sqrt{D}}$. The same relationship would be in effect for crossing $v^2 - u^2$ 2 $\sqrt{v^2 - u^2}$. The same relationship would be in effect for crossing

back, so the time to come back is given by $t_2 = t_1$ and the total time is $t = t_1 + t_2 = \sqrt{\frac{v^2 - u^2}{\sqrt{v^2 - u^2}}}$.
The speed *v* must be greater than the speed *u*. The velocity of the boat relative to the shore when $\frac{D}{2}$. $t = t_1 + t_2 = \boxed{}$. $v^2 - u^2$

going upstream is $v - u$. If $v \lt u$, the boat will not move upstream at all, and so the first part of the trip would be impossible. Also, in part b, we see that ν is longer than μ in the triangle, since ν is the hypotenuse.

67. Choose the origin to be the point from which the projectile is launched, and choose upward as the positive *y* direction. The *y* displacement of the projectile is 155 m, and the horizontal range of the projectile is 195 m. The acceleration in the *y* direction is $a_x = -g$, and the time of flight is 7.6 s.

The horizontal velocity is found from the horizontal motion at constant velocity.

$$
\Delta x = v_x t \rightarrow v_x = \frac{\Delta x}{t} = \frac{195 \text{ m}}{7.6 \text{ s}} = 25.7 \text{ m/s}
$$

Calculate the initial *y* velocity from the given data and Eq. 2-11b.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \rightarrow 155 \text{ m} = v_{y0}(7.6 \text{ s}) + \frac{1}{2}(-9.80 \text{ m/s}^2)(7.6 \text{ s})^2 \rightarrow v_{y0} = 57.6 \text{ m/s}
$$

Thus the initial velocity and direction of the projectile are:
 $\sqrt{a^2 + a^2}$ $\sqrt{(25.7 \text{ m/s})^2 + (57.6 \text{ m/s})^2}$ $\sqrt{(2m/s)^2}$

$$
v_0 = \sqrt{v_x^2 + v_{y0}^2} = \sqrt{(25.7 \text{ m/s})^2 + (57.6 \text{ m/s})^2} = \boxed{63 \text{ m/s}}
$$

$$
\theta = \tan^{-1} \frac{v_{y0}}{v_x} = \tan^{-1} \frac{57.6 \text{ m/s}}{25.7 \text{ m/s}} = \boxed{66^\circ}
$$

68. Choose downward to be the positive *y* direction for this problem.

- (*a*) The vertical component of her acceleration is directed downward, and its magnitude will be given by $a_y = a \sin \theta = (1.80 \text{ m/s}^2) \sin 30.0^\circ = |0.900 \text{ m/s}^2|$.
- (*b*) The time to reach the bottom of the hill is calculated from Eq. 2-11b, with a *y* displacement of 335 m, $v_{y0} = 0$, and $a_y = 0.900 \text{ m/s}^2$. $a_y = 0.900 \text{ m/s}^2$.
 a_t^2 , a_t^2 ,

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \rightarrow 335 \text{ m} = 0 + 0 + \frac{1}{2}(0.900 \text{ m/s}^2)(t)^2 \rightarrow t = \sqrt{\frac{2(335 \text{ m})}{(0.900 \text{ m/s}^2)}} = 27.3 \text{ s}
$$

69. The proper initial speeds will be those for which the ball has traveled a horizontal distance somewhere between 10.78 m and 11.22 m while it changes height from 2.10 m to 2.60 m with a shooting angle of 38.0°. Choose the origin to be at the shooting location of the basketball, with upward as the positive *y* direction. Then the vertical displacement is $y = 0.5$ m, $a_y = -9.80$ m/s², ward as the positive y direction. Then the vertical displacement is $y = 0.5$ m, $a_y = -9.80$ m/s²,
 $y = v_0 \sin \theta_0$, and the (constant) x velocity is $v_x = v_0 \cos \theta_0$. See the diagram (not to scale).

 $v_{y0} = v_0 \sin \theta_0$, and the (constant) *x* velocity is $v_x = v_0 \cos \theta_0$. See the diagram (not to scale).

$$
\Delta x = v_x t = v_0 \cos \theta_0 t \text{ and so } t = \frac{\Delta x}{v_0 \cos \theta_0}.
$$

.

For the vertical motion, applying Eq. 2-11b.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 = v_0 \sin \theta t - \frac{1}{2}gt^2
$$

Substitute the expression for the time of flight and solve for the initial velocity.

$$
y = v_0 \sin \theta t - \frac{1}{2}gt^2 = v_0 \sin \theta \frac{\Delta x}{v_0 \cos \theta_0} - \frac{1}{2}g \left(\frac{\Delta x}{v_0 \cos \theta_0}\right)^2 = \Delta x \tan \theta - \frac{g (\Delta x)^2}{2v_0^2 \cos^2 \theta_0}
$$

$$
v_0 = \sqrt{\frac{g (\Delta x)^2}{2 \cos^2 \theta_0 (-y + \Delta x \tan \theta)}}
$$

For $\Delta x = 10.78$ m, the shortest shot:

$$
v_0 = \sqrt{\frac{(9.80 \text{ m/s}^2)(10.78 \text{ m})^2}{2 \cos^2 38.0^{\circ} \left[(-0.5 \text{ m} + (10.78 \text{ m}) \tan 38.0^{\circ})\right]}} = 10.8 \text{ m/s}.
$$

For $\Delta x = 11.22$ m, the longest shot:

$$
v_0 = \sqrt{\frac{(9.80 \text{ m/s}^2)(11.22 \text{ m})^2}{2 \cos^2 38.0^{\circ} \left[(-0.5 \text{ m} + (11.22 \text{ m}) \tan 38.0^{\circ})\right]}} = 11.0 \text{ m/s}.
$$

- 70. Choose the origin to be the location at water level directly underneath the diver when she left the board. Choose upward as the positive *y* direction. For the diver, $y_0 = 5.0$ m, the final *y* position is $y_0 = 5.0$ m, the final *y* position is *y* = 0.0 m (water level), $a_y = -g$, the time of flight is $t = 1.3$ s, and the horizontal displacement is $x = 3.0$ m.
	- (*a*) The horizontal velocity is determined from the horizontal motion at constant velocity.

$$
\Delta x = v_x t \rightarrow v_x = \frac{\Delta x}{t} = \frac{3.0 \text{ m}}{1.3 \text{ s}} = 2.31 \text{ m/s}
$$

The initial *y* velocity is found using Eq. 2-11b.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \rightarrow 0 \text{ m} = 5.0 \text{ m} + v_{y0} (1.3 \text{ s}) + \frac{1}{2}(-9.80 \text{ m/s}^2)(1.3 \text{ s})^2 \rightarrow
$$

$$
v_{y0} = 2.52 \text{ m/s}
$$

The magnitude and direction of the initial velocity is
\n
$$
v_0 = \sqrt{v_x^2 + v_{y0}^2} = \sqrt{(2.31 \text{ m/s})^2 + (2.52 \text{ m/s})^2} = 3.4 \text{ m/s}
$$
\n
$$
\theta = \tan^{-1} \frac{v_{y0}}{v_x} = \tan^{-1} \frac{2.52 \text{ m/s}}{2.31 \text{ m/s}} = \boxed{48^\circ \text{ above the horizontal}}
$$

(*b*) The maximum height will be reached when the *y* velocity is zero. Use Eq. 2-11c.

$$
v_y^2 = v_{y0}^2 + 2a\Delta y \quad \rightarrow \quad 0 = (2.52 \text{ m/s})^2 + 2(-9.80 \text{ m/s}^2)(y_{\text{max}} - 5.0 \text{ m}) \quad \rightarrow
$$

$$
y_{\text{max}} = 5.3 \text{ m}
$$

(*c*) To find the velocity when she enters the water, the horizontal velocity is the (constant) value of $v_x = 2.31 \text{ m/s}$. The vertical velocity is found from Eq. 2-11a.

$$
v_y = v_{y0} + at = 2.52 \text{ m/s} + (-9.80 \text{ m/s}^2)(1.3 \text{ s}) = -10.2 \text{ m/s}.
$$

The magnitude and direction of this velocity is given by

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$
v = \sqrt{v_x^2 + v_y^2} = \sqrt{(2.31 \text{ m/s})^2 + (-10.2 \text{ m/s})^2} = 10.458 \text{ m/s} \approx \frac{10 \text{ m/s}}{10 \text{ m/s}}
$$

$$
\theta = \tan^{-1} \frac{v_y}{v_x} = \tan^{-1} \frac{-10.2 \text{ m/s}}{2.31 \text{ m/s}} = \boxed{-77^\circ \text{ (below the horizontal)}}
$$

71. (*a*) Choose the origin to be the location where the car leaves the ramp, and choose upward to be the positive *y* direction. At the end of its flight over the 8 cars, the car must be at $y = -1.5$ m.
Also for the car, $v_{y0} = 0$, $a_y = -g$, $v_x = v_0$, and $\Delta x = 20$ m. The time of flight is found from $v_{y0} = 0$, $a_y = -g$, $v_x = v_0$, and $\Delta x = 20$ m. The time of flight is found from the horizontal motion at constant velocity: $\Delta x = v_x t \rightarrow t = \Delta x / v_0$. That expression for the time is used in Eq. 2-11b for the vertical motion.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \rightarrow y = 0 + 0 + \frac{1}{2}(-g)\left(\frac{\Delta x}{v_0}\right)^2 \rightarrow
$$

$$
v_0 = \sqrt{\frac{-g(\Delta x)^2}{2(y)}} = \sqrt{\frac{-(9.80 \text{ m/s}^2)(20 \text{ m})^2}{2(-1.5 \text{ m})}} = \boxed{36 \text{ m/s}}
$$

(*b*) Again choose the origin to be the location where the car leaves the ramp, and choose upward to be the positive *y* direction. The *y* displacement of the car at the end of its flight over the 8 cars must again be $y = -1.5$ m. For the car, $v_{y0} = v_0 \sin \theta_0$, $a_y = -g$, $v_x = v_0 \cos \theta_0$, and $c_x = v_0 \cos \theta_0$, and $v_r = v_0 \cos \theta_0$, and

 $x = 20$ m. The launch angle is $\theta_0 = 10^\circ$. The time of flight is found from the horizontal motion at constant velocity.

$$
\Delta x = v_x t \quad \rightarrow \quad t = \frac{\Delta x}{v_0 \cos \theta_0}
$$

That expression for the time is used in Eq. 2-11b for the vertical motion.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \rightarrow y = v_0 \sin \theta_0 \frac{\Delta x}{v_0 \cos \theta_0} + \frac{1}{2}(-g) \left(\frac{\Delta x}{v_0 \cos \theta_0}\right)^2 \rightarrow
$$

$$
v_0 = \sqrt{\frac{g(\Delta x)^2}{2(\Delta x \tan \theta_0 - y)\cos^2 \theta_0}} = \sqrt{\frac{(9.80 \text{ m/s}^2)(20 \text{ m})^2}{2((20 \text{ m})\tan 10^\circ + 1.5 \text{ m})\cos^2 10^\circ}} = \boxed{20 \text{ m/s}}
$$

- 72. Choose the origin to be the point at ground level directly below where the ball was hit. Call upwards the positive *y* direction. For the ball, we have $v_0 = 28 \text{ m/s}$, $\theta_0 = 61^\circ$, $a_y = -g$, $y_0 = 0.9 \text{ m}$, and $y_0 = 0.9$ m, and $y = 0.0$ m.
	- (*a*) To find the horizontal displacement of the ball, the horizontal velocity and the time of flight are needed. The (constant) horizontal velocity is given by $v_x = v_0 \cos \theta_0$. The time of flight is found from Eq. 2-11b.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 \rightarrow 0 = y_0 + v_0 \sin \theta_0 t - \frac{1}{2}gt^2 \rightarrow
$$

$$
t = \frac{-v_0 \sin \theta_0 \pm \sqrt{v_0^2 \sin^2 \theta_0 - 4(-\frac{1}{2}g)y_0}}{2(-\frac{1}{2}g)}
$$

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$
=\frac{-\left(28 \,\mathrm{m/s}\right) \sin 61^\circ \pm \sqrt{\left(28 \,\mathrm{m/s}\right)^2 \sin^2 61^\circ - 4\left(-\frac{1}{2}\right) \left(9.80 \,\mathrm{m/s}^2\right) \left(0.9 \,\mathrm{m}\right)}}{2\left(-\frac{1}{2}\right) \left(9.80 \,\mathrm{m/s}^2\right)}
$$

 5.034 s, -0.0365 s

Choose the positive time, since the ball was hit at $t = 0$. The horizontal displacement of the ball will be found by the constant velocity relationship for horizontal motion.

 $\binom{0}{5}$ (5.024a) 69.24 m = 69.34 m = 69.34 $x = v_x t = v_0 \cos \theta_0 t = (28 \text{ m/s})(\cos 61^\circ)(5.034 \text{ s}) = 68.34 \text{ m} \approx 68 \text{ m}$

(*b*) The center fielder catches the ball right at ground level. He ran $105 \text{ m} - 68.34 \text{ m} = 36.66 \text{ m}$ to catch the ball, so his average running speed would be

$$
v_{avg} = \frac{\Delta d}{t} = \frac{36.66 \text{ m}}{5.034 \text{ s}} = 7.282 \text{ m/s} \approx 7.3 \text{ m/s}
$$

73. Since the ball is being caught at the same height from which it was struck, use the range formula to find the catching ball horizontal distance the ball travels.

$$
R = \frac{v_0^2 \sin 2\theta_0}{g} = \frac{(32 \text{ m/s})^2 \sin (2 \times 55^\circ)}{9.8 \text{ m/s}^2} = 98.188 \text{ m}
$$
 98.188 m

Then as seen from above, the location of home plate, the point where $\frac{1}{85 \text{ m}}$ the ball must be caught, and the initial location of the outfielder are shown in the diagram. The dark arrow shows the direction in which the outfielder must run. The length of that distance is found from the law of cosines as applied to the triangle.

$$
x = \sqrt{a^2 + b^2 - 2ab\cos\theta}
$$

= $\sqrt{98.188^2 + 85^2 - 2(98.188)(85)\cos 22^\circ} = 37.27$ m

The angle θ at which the outfielder should run is found from the law of sines.

$$
\frac{\sin 22^{\circ}}{x} = \frac{\sin \theta}{98 \text{ m}} \quad \rightarrow \quad \theta = \sin^{-1} \left(\frac{98.188}{37.27} \sin 22^{\circ} \right) = 81^{\circ} \text{ or } 99^{\circ}
$$

Since $98.188^2 > 85^2 + 37.27^2$, the angle must be obtuse, so we choose $\theta = 97^{\circ}$. 97° . Assume that the outfielder's time for running is the same as the time of flight of the ball. The time of flight of the ball is found from the horizontal motion of the ball at constant velocity.

$$
R = v_x t = v_0 \cos \theta_0 t \quad \rightarrow \quad t = \frac{R}{v_0 \cos \theta_0} = \frac{98.188 \text{ m}}{(32 \text{ m/s}) \cos 55^\circ} = 5.35 \text{ s}
$$

Thus the average velocity of the outfielder must be $v_{avg} = \frac{2.00 \text{ m/s}}{t} = \frac{5.35 \text{ s}}{5.35 \text{ s}} = 7.0 \text{ m/s}$ at an angle of 37.27 m $7.0 \,\mathrm{m/s}$ at an angle of $v_{\text{ave}} = \frac{\Delta d}{\Delta t} = \frac{37.27 \text{ m}}{2.5 \text{ s}} = 7.0 \text{ m/s}$ at an angle of $t = 5.35 \text{ s}$ at the average velocity of the outfielder must be $v_{avg} = \frac{2a}{t} = \frac{64.24 \text{ m/s}}{5.35 \text{ s}} = 7.0 \text{ m/s}$ at an angle of

 $|97°|$ relative to the outfielder's line of sight to home plate.

74. Choose the origin to be the point at the top of the building from which the ball is shot, and call upwards the positive *y* direction. The initial velocity is $v_0 = 18 \text{ m/s}$ at an angle of $\theta_0 = 42^\circ$. The $_{0}$ – $_{+2}$. The 42° . The acceleration due to gravity is $a_y = -g$.

(a)
$$
v_x = v_0 \cos \theta_0 = (18 \text{ m/s}) \cos 42^\circ = 13.38 \approx \frac{13 \text{ m/s}}{13 \text{ m/s}}
$$

 $v_{y0} = v_0 \sin \theta_0 = (18 \text{ m/s}) \sin 42^\circ = 12.04 \approx \frac{12 \text{ m/s}}{12 \text{ m/s}}$

(*b*) Since the horizontal velocity is known and the horizontal distance is known, the time of flight can be found from the constant velocity equation for horizontal motion.

$$
\Delta x = v_x t \rightarrow t = \frac{\Delta x}{v_x} = \frac{55 \text{ m}}{13.38 \text{ m/s}} = 4.111 \text{ s}
$$

With that time of flight, calculate the vertical position of the ball using Eq. 2-11b.

$$
y = y_0 + v_{y0}t + \frac{1}{2}a_yt^2 = (12.04 \text{ m/s})(4.111 \text{ s}) + \frac{1}{2}(-9.80 \text{ m/s}^2)(4.111 \text{ s})^2
$$

$$
= -33.3 = -33 \text{ m}
$$

So the ball will strike 33 m below the top of the building.

75. When shooting the gun vertically, half the time of flight is spent moving upwards. Thus the upwards flight takes two seconds. Choose upward as the positive *y* direction. Since at the top of the flight, the vertical velocity is zero, find the launching velocity from Eq. 2-11a.

$$
v_y = v_{y0} + at \rightarrow v_{y0} = v_y - at = 0 = (9.8 \text{ m/s}^2)(2.0 \text{ s}) = 19.6 \text{ m/s}
$$

Using this initial velocity and an angle of 45° in the range formula will give the maximum range for the gun.

$$
R = \frac{v_0^2 \sin 2\theta_0}{g} = \frac{(19.6 \text{ m/s})^2 \sin (2 \times 45^\circ)}{9.80 \text{ m/s}^2} = 39 \text{ m}
$$

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$
(W/t)_{\text{surings}} = (W/t)_{5300} - (W/t)_{500} = (5300 \text{ W} - 500 \text{ W}) \left(\frac{(273 + 32) \text{ K}}{(273 + 21) \text{ K}} - 1 \right) = 180 \text{ W}
$$

68. To find the mass of water removed, find the energy that is removed from the low temperature reservoir from the work input and the Carnot efficiency. Then use the latent heat of vaporization to determine the mass of water from the energy required for the condensation. Note that the heat of vaporization used is that given in chapter 14 for evaporation at 20° C.

$$
e = 1 - \frac{T_{\rm L}}{T_{\rm H}} = \frac{W}{Q_{\rm H}} = \frac{W}{W + Q_{\rm L}} \longrightarrow Q_{\rm L} = W \frac{T_{\rm L}}{(T_{\rm H} - T_{\rm L})} = mL_{\rm vapor}
$$

$$
m = \frac{W}{L_{\rm vapor}} \frac{T_{\rm L}}{(T_{\rm H} - T_{\rm L})} = \frac{(600 \text{ W})(3600 \text{ s}) (273 + 8) \text{ K}}{(2.45 \times 10^6 \text{ J/kg}) (17 \text{ K})} = 14.6 \text{ kg}
$$

CHAPTER 4: Dynamics: Newton's Laws of Motion

Answers to Questions

- 1. The child tends to remain at rest (Newton's $1st Law$), unless a force acts on her. The force is applied to the wagon, not the child, and so the wagon accelerates out from under the child, making it look like the child falls backwards relative to the wagon. If the child is standing in the wagon, the force of friction between the child and the bottom of the wagon will produce an acceleration of the feet, pulling the feet out from under the child, also making the child fall backwards.
- 2. (*a*) Mary sees the box stay stationary with respect to the ground. There is no horizontal force on the box since the truck bed is smooth, and so the box cannot accelerate. Thus Mary would describe the motion of the box in terms of Newton's $1st$ law – there is no force on the box, so it does not accelerate.
	- (*b*) Chris, from his non-inertial reference frame, would say something about the box being "thrown" backwards in the truck, and perhaps use Newton's $2nd$ law to describe the effects of that force. But the source of that force would be impossible to specify.
- 3. If the acceleration of an object is zero, then by Newton's second law, the *net* force must be zero. There can be forces acting on the object as long as the vector sum of the forces is zero.
- 4. If only once force acts on the object, then the net force cannot be zero. Thus the object cannot have zero acceleration, by Newton's second law. The object can have zero velocity for an instant. For example, an object thrown straight up under the influence of gravity has a velocity of zero at the top of its path, but has a non-zero net force and non-zero acceleration throughout the entire flight.
- 5. (*a*) A force is needed to bounce the ball back up, because the ball changes direction, and so accelerates. If the ball accelerates, there must be a force.
	- (*b*) The pavement exerts the force on the golf ball.
- 6. When you try to walk east, you push on the ground (or on the log in this case) with a westward force. When you push westward on the massive Earth, the Earth moves imperceptibly, but by Newton's 3rd law there is an eastward force on you, which propels you forward. When walking on the log, the relatively light and unrestricted log is free to move, and so when you push it westward, it moves westward as you move eastward.
- 7. By Newton's 3rd law, the desk or wall exerts a force on your foot equal in magnitude to the force with which you hit the desk or wall. If you hit the desk or wall with a large force, then there will be a large force on your foot, causing pain. Only a force on your foot causes pain.
- 8. (*a*) When you are running, the stopping force is a force of friction between your feet and the ground. You push forward with your feet on the ground, and thus the ground pushes backwards on you, slowing your speed.
	- (*b*) A fast person can run about 10 meters per second, perhaps takes a distance of 5 meters over which to stop. Those 5 meters would be about 5 strides, of 1 meter each. The acceleration can be found from Eq. 2-11c.

$$
v^2 - v_0^2 = 2a(x - x_0)
$$
 $\rightarrow a = \frac{v^2 - v_0^2}{2(x - x_0)} = \frac{0 - (10 \text{ m/s})^2}{10 \text{ m}} = -10 \text{ m/s}^2$

9. When giving a sharp pull, the key is the suddenness of the application of the force. When a large, sudden force is applied to the bottom string, the bottom string will have a large tension in it. Because of the stone's inertia, the upper string does not immediately experience the large force. The bottom string must have more tension in it, and will break first.

If a slow and steady pull is applied, the tension in the bottom string increases. We approximate that condition as considering the stone to be in equilibrium until the string breaks. The free-body diagram for the stone would look like this diagram. While the stone is in equilibrium, Newton's 2^{nd} law states that $F_{up} = F_{down} + mg$.

 $\dot{\mathbf{F}}_{\mathsf{up}}$ \rightarrow $\dot{\mathbf{F}}_{\text{down}}$ \vec{F}_{down} \overrightarrow{mg} \rightarrow stone

Thus the tension in the upper string is going to be larger than the tension in the l ower string because of the weight of the stone, and so the upper string will break first.

- 10. The acceleration of both rocks is found by dividing their weight (the force of gravity on them) by their mass. The 2-kg rock has a force of gravity on it that is twice as great as the force of gravity o n the 1-kg rock, but also twice as great a mass as the 1-kg rock, so the acceleration is the same for both.
- 11. Only the pounds reading would be correct. The spring scale works on the fact that a certain **force** due to gravity is smaller by a factor of 6 on the moon, the weight of the object is smaller by a factor The mass itself doesn't change when moving to the Moon, and so a mass reading on the Moon would (the weight of the object being weighed) will stretch the spring a certain distance. That distance is proportional to the product of the mass and the acceleration due to gravity. Since the acceleration of 6, and the spring will be pulled to only one-sixth of the distance that it was pulled on the Earth. be incorrect.
- 12. When you pull the rope at an angle, only the horizontal component of the pulling force will be accelerating the box across the table. This is a smaller horizontal force than originally used, and so the horizontal acceleration of the box will decrease.
- 13. Let us find the acceleration of the Earth, assuming the mass of the freely falling object is $m = 1$ kg. If the mass of the Earth is M , then the acceleration of the Earth would be found using Newton's $3rd$ law and Newton's $2nd$ law.

$$
F_{\text{Earth}} = F_{\text{object}} \rightarrow Ma_{\text{Earth}} = mg \rightarrow a_{\text{Earth}} = g m/M
$$

Since the Earth has a mass that is on the order of 10^{25} kg, then the acceleration of the Earth is on the order of $10^{-25} g$, or about 10^{-24} m/s². This tiny acceleration is undetectable.

- 4. (*a*) To lift the object on the Earth requires a force the same size as its weight on Earth, 1 $F_{\text{Earth}} = mg_{\text{Earth}} = 98 \text{ N}$. To lift the object on the Moon requires a force the same size as its weight on the Moon, $F_{\text{Moon}} = mg_{\text{Moon}} = mg_{\text{Moon}} / 6 = 16 \text{ N}$.
	- (b) The horizontal accelerating force would be the same in each case, because the mass of the acceleration to throw them with the same speed. So by Newton's second law, the forces would object is the same on both the Earth and the Moon, and both objects would have the same have to be the same.
- 5. In a tug of war, the team that pushes hardest against the ground wins. It is true that both teams have 1 the same force on them due to the tension in the rope. But the winning team pushes harder against the ground and thus the ground pushes harder on the winning team, making a net unbalanced force.

The free body diagram below illustrates this. The forces are \vec{F}_{T_1G} , the force on team 1 from the ground, $\vec{F}_{T,G}$, the force on team 2 from the ground, and \vec{F}_{TR} , the force on each team from the rope.

- 16. (*a*) The magnitude is 40 N.
	- (*b*) The direction is downward.
	- (*c*) It is exerted on the person.
	- (*d*) It is exerted by the bag of groceries.
- 17. If you are at rest, the net force on you is zero. Hence the ground exerts a force on you exactly equal to your weight. The two forces acting on you sum to zero, and so you don't accelerate. If you squat down and then push with a larger force against the ground, the ground then pushes back on you with a larger force by Newton's third law, and you can then rise into the air.
- 18. In a whiplash situation, the car is violently pushed forward. Since the victim's back is against the seat of the car, the back moves forward with the car. But the head has no direct horizontal force to push it, and so it "lags behind". The victim's body is literally pushed forward, out from under their head – the head is not thrown backwards. The neck muscles must eventually pull the head forward, and that causes the whiplash. To avoid this, use the car's headrests.
- 19. The truck bed exerts a force of static friction on the crate, causing the crate to accelerate.
- 20. On the way up, there are two forces on the block that are parallel to each other causing the deceleration – the component of weight parallel to the plane, and the force of friction on the block. Since the forces are parallel to each other, both pointing down the plane, they add, causing a larger magnitude force and a larger acceleration. On the way down, those same two forces are opposite of each other, because the force of friction is now directed up the plane. With these two forces being opposite of each other, their net force is smaller, and so the acceleration is smaller.
- 21. Assume your weight is *W*. If you weighed yourself on an inclined plane that is inclined at angle θ , the bathroom scale would read the magnitude of the normal force between you and the plane, which would be $W \cos \theta$.

Solutions to Problems

1. Use Newton's second law to calculate the force.

$$
\sum F = ma = (60.0 \text{ kg})(1.25 \text{ m/s}^2) = 75.0 \text{ N}
$$

2. Use Newton's second law to calculate the mass.

$$
\sum F = ma \rightarrow m = \frac{\sum F}{a} = \frac{265 \text{ N}}{2.30 \text{ m/s}^2} = \boxed{115 \text{ kg}}
$$

*m***g** G

 $\dot{\mathbf{F}}_{\text{N1}} = \dot{\mathbf{F}}_{12}$ $\overline{}$

Top \vert box $(\#1)$

 m_1 \vec{g} $\overline{}$

 $\dot{\mathbf{F}}_{\rm N}$ \rightarrow

3. Use Newton's second law to calculate the tension.

$$
\sum F = F_{\rm T} = ma = (960 \text{ kg})(1.20 \text{ m/s}^2) = \boxed{1.15 \times 10^3 \text{ N}}
$$

- 4. In all cases, $W = mg$, where *g* changes with location.
- (*a*) $W_{\text{Earth}} = m g_{\text{Earth}} = (76 \text{ kg}) (9.8 \text{ m/s}^2) = 7.4 \times 10^2 \text{ N}$

(b)
$$
W_{\text{Moon}} = mg_{\text{Moon}} = (76 \text{ kg})(1.7 \text{ m/s}^2) = 1.3 \times 10^2 \text{ N}
$$

(c)
$$
W_{\text{Mars}} = mg_{\text{Mars}} = (76 \text{ kg})(3.7 \text{ m/s}^2) = 2.8 \times 10^2 \text{ N}
$$

(d)
$$
W_{\text{space}} = mg_{\text{space}} = (76 \text{ kg})(0 \text{ m/s}^2) = 0 \text{ N}
$$

- 5. (*a*) The 20.0 kg box resting on the table has the free-body diagram shown. Its weight is $mg = (20.0 \text{ kg})(9.80 \text{ m/s}^2) = 196 \text{ N}$. Since the box is at rest, the net force on the box must be 0, and so the normal force must also be $\sqrt{196 N}$.
	- (*b*) Free-body diagrams are shown for both boxes. \vec{F}_{12} is the force on box 1 (the top box) due to box 2 (the bottom box), and is the normal force on box 1. \mathbf{F}_{21} is the force on box 2 due to box 1, and has the same magnitude as \vec{F}_{12} by $\overline{}$ Newton's $3rd$ law. \vec{F}_{N2} is the force of the table on box 2. That is the normal force on box 2. Since both boxes are at rest, the net force on each box must be 0. Write Newton's $2nd$ law in the vertical direction for each box, taking the $\overline{}$ upward direction to be positive.

$$
\sum F_1 = F_{N1} - m_1 g = 0
$$

\n
$$
F_{N2} = m_1 g = (10.0 \text{ kg})(9.80 \text{ m/s}^2) = 98.0 \text{ N} = F_{12} = F_{21}
$$

\n
$$
\sum F_2 = F_{N2} - F_{21} - m_2 g = 0
$$

\n
$$
F_{N2} = F_{21} + m_2 g = 98.0 \text{ N} + (20.0 \text{ kg})(9.80 \text{ m/s}^2) = 294 \text{ N}
$$

\n
$$
m_2 \vec{g} + \vec{F}_{21}
$$

6. Find the average acceleration from Eq. 2-2. The average force on the car is found from Newton's second law.

$$
v = 0 \t v_0 = (95 \text{ km/h}) \left(\frac{0.278 \text{ m/s}}{1 \text{ km/h}} \right) = 26.4 \text{ m/s} \t a_{\text{avg}} = \frac{v - v_0}{t} = \frac{0 - 26.4 \text{ m/s}}{8.0 \text{ s}} = -3.30 \text{ m/s}^2
$$

$$
F_{\text{avg}} = ma_{\text{avg}} = (1100 \text{ kg}) \left(-3.3 \text{ m/s}^2 \right) = \boxed{-3.6 \times 10^3 \text{ N}}
$$

The negative sign indicates the direction of the force, in the opposite direction to the initial velocity.

7. The average force on the pellet is its mass times its average acceleration. The average acceleration is found from Eq. 2-11c. For the pellet, $v_0 = 0$, $v = 125 \text{ m/s}$, and $x - x_0 = 0.800 \text{ m}$.

$$
a_{\text{avg}} = \frac{v^2 - v_0^2}{2(x - x_0)} = \frac{(125 \text{ m/s})^2 - 0}{2(0.800 \text{ m})} = 9770 \text{ m/s}^2
$$

$$
F_{\text{avg}} = ma_{\text{avg}} = (7.00 \times 10^{-3} \text{ kg})(9770 \text{ m/s}^2) = 68.4 \text{ N}
$$

*m***g** G

 \mathbf{F}_{T}

 \mathbf{F}_{T} $\overline{}$

 \mathbf{F}_{T} $\overline{}$

8. We assume that the fishline is pulling vertically on the fish, and that the fish is not jerking the line. A free-body diagram for the fish is shown. Write Newton's $2nd$ law for the fish in the vertical direction, assuming that up is positive. The tension is at its maximum.

$$
\sum F = F_{\rm T} - mg = ma \rightarrow F_{\rm T} = m(g + a) \rightarrow
$$

$$
m = \frac{F_{\rm T}}{g + a} = \frac{22 \text{ N}}{9.8 \text{ m/s}^2 + 2.5 \text{ m/s}^2} = 1.8 \text{ kg}
$$

Thus a mass of 1.8 kg is the maximum that the fishline will support with the given acceleration. Since the line broke, the fish's mass must be greater than 1.8 kg (about 4 lbs).

9. The problem asks for the average force on the glove, which in a direct calculation would require knowledge about the mass of the glove and the acceleration of the glove. But no information about the glove is given. By Newton's $3rd$ law, the force exerted by the ball on the glove is equal and opposite to the force exerted by the glove on the ball. So calculate the average force on the ball, and then take the opposite of that result to find the average force on the glove. The average force on the ball is its mass times its average acceleration. Use Eq. 2-11c to find the acceleration of the ball, with $v = 0$, $v_0 = 35.0$ m/s, and $x - x_0 = 0.110$ m. The initial direction of the ball is the positive direction.

$$
a_{\text{avg}} = \frac{v^2 - v_0^2}{2(x - x_0)} = \frac{0 - (35.0 \text{ m/s})^2}{2(0.110 \text{ m})} = -5568 \text{ m/s}^2
$$

$$
F_{\text{avg}} = ma_{\text{avg}} = (0.140 \text{ kg})(-5568 \text{ m/s}^2) = \boxed{-7.80 \times 10^2 \text{ N}}
$$

Thus the average force on the glove was 780 N, in the direction of the initial velocity of the ball.

 $\boxed{10}$. Choose up to be the positive direction. Write Newton's $2nd$ law for the vertical direction, and solve for the tension force.

$$
\sum F = F_{\rm T} - mg = ma \rightarrow F_{\rm T} = m(g + a)
$$

F_{\rm T} = (1200 \text{ kg})(9.80 \text{ m/s}^2 + 0.80 \text{ m/s}^2) = 1.3 \times 10^4 \text{ N}

11. Use Eq. 2-11b with $v_0 = 0$ to find the acceleration.

$$
x - x_0 = v_0 t + \frac{1}{2} a t^2 \rightarrow a = \frac{2(x - x_0)}{t^2} = \frac{2(402 \text{ m})}{(6.40 \text{ s})^2} = 19.6 \text{ m/s}^2 \left(\frac{1 \text{ "g"}}{9.80 \text{ m/s}^2}\right) = \boxed{2.00 \text{ g's}}
$$

The accelerating force is found by Newton's 2nd law.

 $F = ma = (485 \text{ kg})(19.6 \text{ m/s}^2) = 9.51 \times 10^3 \text{ N}$

12. Choose up to be the positive direction. Write Newton's $2nd$ law for the vertical direction, and solve for the acceleration.

$$
\sum F = F_{\text{T}} - mg = ma
$$

$$
a = \frac{F_{\text{T}} - mg}{m} = \frac{163 \text{ N} - (12.0 \text{ kg}) (9.80 \text{ m/s}^2)}{12.0 \text{ kg}} = \boxed{3.8 \text{ m/s}^2}
$$

Since the acceleration is positive, the bucket has an upward acceleration.

13. In both cases, a free-body diagram for the elevator would look like the adjacent diagram. Choose up to be the positive direction. To find the MAXIMUM tension, assume that the acceleration is up. Write Newton's $2nd$ law for the elevator.

$$
\sum F = ma = F_{\text{T}} - mg \rightarrow
$$

F_{\text{T}} = ma + mg = m(a + g) = m(0.0680g + g) = (4850 \text{ kg})(1.0680)(9.80 \text{ m/s}^2)
= $\sqrt{5.08 \times 10^4 \text{ N}}$

To find the MINIMUM tension, assume that the acceleration is down. Then Newton's $2nd$ law for the elevator becomes

$$
\sum F = ma = F_{\rm T} - mg \rightarrow F_{\rm T} = ma + mg = m(a + g) = m(-0.0680g + g)
$$

$$
= (4850 \text{ kg})(0.9320)(9.80 \text{ m/s}^2) = 4.43 \times 10^4 \text{ N}
$$

14. If the thief were to hang motionless on the sheets, or descend at a constant speed, the sheets would not support him, because they would have to support the full 75 kg. But if he descends with an acceleration, the sheets will not have to support the total mass. A freebody diagram of the thief in descent is shown. If the sheets can support a mass of 58 kg, then the tension force that the sheets can exert is $F_T = (58 \text{ kg})(9.8 \text{ m/s}^2) = 570 \text{ N}$.

Assume that is the tension in the sheets. Then write Newton's $2nd$ law for the thief, taking the upward direction to be positive.

$$
\sum F = F_{\rm T} - mg = ma \rightarrow a = \frac{F_{\rm T} - mg}{m} = \frac{570 \text{ N} - (75 \text{ kg})(9.80 \text{ m/s}^2)}{75 \text{ kg}} = -2.2 \text{ m/s}^2
$$

The negative sign shows that the acceleration is downward.
If the thief descends with an acceleration of 2.2 m/s² or greater, the sheets will support his descent.

15. There will be two forces on the person – their weight, and the normal force of the scales pushing up on the person. A free-body diagram for the person is shown. Choose up to be the positive direction, and use Newton's $2nd$ law to find the acceleration.

$$
\sum F = F_{N} - mg = ma \rightarrow 0.75mg - mg = ma \rightarrow
$$

a = -0.25g = -0.25(9.8 m/s²) = -2.5 m/s²

Due to the sign of the result, the direction of the acceleration is down. Thus the elevator must have started to move down since it had been motionless.

16. Choose UP to be the positive direction. Write Newton's $2nd$ law for the elevator.

$$
\sum F = F_{\rm T} - mg = ma \rightarrow
$$
\n
$$
a = \frac{F_{\rm T} - mg}{m} = \frac{21,750 \text{ N} - (2125 \text{ kg})(9.80 \text{ m/s}^2)}{2125 \text{ kg}} = 0.4353 \text{ m/s}^2 \approx \boxed{0.44 \text{ m/s}^2}
$$

*m***g**

 \vec{g} \overrightarrow{F}_{N} \overline{a}

 $\overline{}$

*m***g** $\overline{}$

 $\dot{\mathbf{F}}_{\text{T}}$ $\overline{}$

17. (*a*) There will be two forces on the skydivers – their combined weight, and the upward force of air resistance, \vec{F}_A . Choose up to be the positive direction. Write Newton's $2nd$ law for the skydivers.

$$
\sum F = F_A - mg = ma \rightarrow 0.25mg - mg = ma \rightarrow
$$

$$
a = -0.75g = -0.75(9.8 \text{ m/s}^2) = [-7.4 \text{ m/s}^2]
$$

Due to the sign of the result, the direction of the acceleration is down.

 (*b*) If they are descending at constant speed, then the net force on them must be zero, and so the force of air resistance must be equal to their weight.

$$
F_{\rm A} = mg = (132 \text{ kg})(9.80 \text{ m/s}^2) = 1.29 \times 10^3 \text{ N}
$$

18. (*a*) Use Eq. 2-11c to find the speed of the person just before striking the ground. Take down to be the positive direction. For the person, $v_0 = 0$, $y - y_0 = 3.9$ m, and $a = 9.8$ m/s².

$$
v^2 - v_0^2 = 2a(y - y_0) \rightarrow v = \sqrt{2a(y - y_0)} = \sqrt{2(9.8 \text{ m/s}^2)(3.9 \text{ m})} = 8.743 = 8.743 \text{ m/s}
$$

 (*b*) For the deceleration, use Eq. 2-11c to find the average deceleration, choosing down to be positive.

$$
v_0 = 8.743 \text{ m/s}
$$
 $v = 0$ $y - y_0 = 0.70 \text{ m}$ $v^2 - v_0^2 = 2a(y - y_0)$ \rightarrow

$$
a = \frac{-v_0^2}{2\Delta y} = \frac{-(8.743 \text{ m/s})^2}{2(0.70 \text{ m})} = -54.6 \text{ m/s}^2
$$

The average force is found from Newton's $2nd$ law.

$$
F = ma = (42 \text{ kg})(-54.6 \text{ m/s}^2) = \boxed{-2.3 \times 10^3 \text{ N}}.
$$

The negative sign shows that the force is in the negative direction, which is upward.

- 19. Free body diagrams for the box and the weight are shown below. The tension exerts the same magnitude of force on both objects.
	- (*a*) If the weight of the hanging weight is less than the weight of the box, the objects will not move, and the tension will be the same as the weight of the hanging weight. The acceleration of the box will also be zero, and so the sum of the forces on it will be zero. For the box,

 $\mathbf{F}_{\rm N}$

 $\overline{}$

 \vec{F} \vec{g} $m\vec{g}$ | \vec{g} | \vec{g} \vec{g}

$$
F_{\rm N} + F_{\rm T} - m_1 g = 0 \rightarrow F_{\rm N} = m_1 g - F_{\rm T} = m_1 g - m_2 g = 77.0 \text{N} - 30.0 \text{ N} = 47.0 \text{ N}
$$

(*b*) The same analysis as for part (*a*) applies here.

$$
F_{\rm N} = m_{\rm I}g - m_{\rm 2}g = 77.0 \text{ N} - 60.0 \text{ N} = 17.0 \text{ N}
$$

- (*c*) Since the hanging weight has more weight than the box on the table, the box on the table will be lifted up off the table, and normal force of the table on the box will be $\vert 0 \text{ N} \vert$.
- 20. (*a*) Just before the player leaves the ground on a jump, the forces on the player would be his weight and the force of the floor pushing up the player. If the player is jumping straight up, then the force of the floor pushing on the player will be straight up – a normal force. See the first diagram. In this case, while they are touching the floor, $F_N > mg$.
	- (*b*) While the player is in the air, the only force on the player is their weight. See the second diagram.

73

 $\overline{}$

- 21. (*a*) Just as the ball is being hit, if we ignore air resistance, there are two main forces on the ball – the weight of the ball, and the force of the bat on the ball.
	- (*b*) As the ball flies toward the outfield, the only force on it is its weight, if air resistance is ignored.
- 22. The two forces must be oriented so that the northerly component of the first force is exactly equal to the southerly component of the second force. Thus the second force must act southwesterly. See the diagram.
- 23. Consider the point in the rope directly below Arlene. That point can be analyzed as having three forces on it – Arlene's weight, the tension in the rope towards the right point of connection, and the tension in the rope towards the left point of connection. Assuming the rope is massless, those two tensions will be of the same

 $T_1 + \dot{F}_2$ 10° 10^o *m***g** $\ddot{}$ \mathbf{F}_{T} \vec{F}_{T} **F** $\overline{}$

magnitude. Since the point is not accelerating the sum of the forces must be zero. In particular, consider the sum of the vertical forces on that point, with UP as the positive direction.

$$
\sum F = F_{\text{T}} \sin 10.0^{\circ} + F_{\text{T}} \sin 10.0^{\circ} - mg = 0 \rightarrow
$$

$$
F_{\text{T}} = \frac{mg}{2 \sin 10.0^{\circ}} = \frac{(50.0 \text{ kg})(9.80 \text{ m/s}^2)}{2 \sin 10.0^{\circ}} = \frac{1.41 \times 10^3 \text{ N}}{1.41 \times 10^3 \text{ N}}
$$

24. The net force in each case is found by vector addition with components.

(a)
$$
F_{\text{Net x}} = -F_1 = -10.2 \text{ N}
$$
 $F_{\text{Net y}} = -F_2 = -16.0 \text{ N}$
 $F_{\text{Net}} = \sqrt{(-10.2)^2 + (-16.0)^2} = \boxed{19.0 \text{ N}}$ $\theta = \tan^{-1} \frac{-16.0}{-10.2} = 57.5^{\circ}$
The actual angle from the x-axis is then 237.5°.

$$
a = \frac{F_{\text{Net}}}{m} = \frac{19.0 \text{ N}}{27.0 \text{ kg}} = \boxed{0.703 \text{ m/s}^2} \text{ at } \boxed{237^\circ}
$$

(b)
$$
F_{\text{Net}x} = F_1 \cos 30^\circ = 8.83 \text{ N}
$$
 $F_{\text{Net}y} = F_2 - F_1 \sin 30^\circ = 10.9 \text{ N}$
\n $F_{\text{Net}} = \sqrt{(8.83 \text{ N})^2 + (10.9 \text{ N})^2} = \boxed{14.0 \text{ N}}$ $\theta = \tan^{-1} \frac{10.9}{8.83} = \boxed{51.0^\circ}$
\n $a = \frac{F_{\text{Net}}}{m} = \frac{14.0 \text{ N}}{27.0 \text{ kg}} = \boxed{0.520 \text{ m/s}^2} \text{ at } \boxed{51.0^\circ}$

 $\dot{\mathbf{F}}_{\text{net}}$ θ \overline{a} $\vec{\mathbf{F}}$ $\vec{\mathbf{F}}$ _{net} \rightarrow $\overline{30^{\circ}}$

25. We draw free-body diagrams for each bucket.

(*a*) Since the buckets are at rest, their acceleration is 0. Write Newton's $2nd$ law for each bucket, calling UP the positive direction.

$$
\sum F_1 = F_{T1} - mg = 0 \rightarrow
$$

\n
$$
F_{T1} = mg = (3.2 \text{ kg})(9.8 \text{ m/s}^2) = 31 \text{ N}
$$

\n
$$
\sum F_2 = F_{T2} - F_{T1} - mg = 0 \rightarrow
$$

\n
$$
F_{T2} = F_{T1} + mg = 2mg = 2(3.2 \text{ kg})(9.8 \text{ m/s}^2) = 63 \text{ N}
$$

 $\overline{}$

 $\dot{\mathbf{F}}_1$

F2

 (*b*) Now repeat the analysis, but with a non-zero acceleration. The free-body diagrams are unchanged.

$$
\sum F_1 = F_{T1} - mg = ma \rightarrow
$$

\n
$$
F_{T1} = mg + ma = (3.2 \text{ kg})(9.80 \text{ m/s}^2 + 1.60 \text{ m/s}^2) = 36 \text{ N}
$$

\n
$$
\sum F_2 = F_{T2} - F_{T1} - mg = ma \rightarrow F_{T2} = F_{T1} + mg + ma = 2F_{T1} = 73 \text{ N}
$$

26. (*a*) We assume that the mower is being pushed to the right. \vec{F}_{fr} is the friction force, and \mathbf{F}_{P} is the pushing force along the handle. \rightarrow

(*b*) Write Newton's $2nd$ law for the horizontal direction. The forces must sum to 0 since the mower is not accelerating.

$$
\sum F_x = F_{p} \cos 45.0^{\circ} - F_{fr} = 0 \rightarrow
$$

F_{fr} = F_p cos 45.0^o = (88.0 N) cos 45.0^o = 62.2 N

(*c*) Write Newton's $2nd$ law for the vertical direction. The forces must sum to 0 since the mower is not accelerating in the vertical direction.

$$
\sum F_y = F_N - mg - F_P \sin 45.0^\circ = 0 \rightarrow
$$

F_N = mg + F_P sin 45° = (14.0 kg)(9.80 m/s²) + (88.0 N) sin 45.0° = 199 N

(*d*) First use Eq. 2-11a to find the acceleration.

$$
v - v_0 = at
$$
 \rightarrow $a = \frac{v - v_0}{t} = \frac{1.5 \text{ m/s} - 0}{2.5 \text{ s}} = 0.60 \text{ m/s}^2$

Now use Newton's $2nd$ law for the *x* direction to find the necessary pushing force.

$$
\sum F_x = F_p \cos 45.0^\circ - F_f = ma \rightarrow
$$

$$
F_p = \frac{F_f + ma}{\cos 45.0^\circ} = \frac{62.2 \text{ N} + (14.0 \text{ kg})(0.60 \text{ m/s}^2)}{\cos 45.0^\circ} = 99.9 \text{ N}
$$

27. Choose the *y* direction to be the "forward" direction for the motion of the snowcats, and the *x* direction to be to the right on the diagram in the textbook. Since the housing unit moves in the forward direction on a straight line, there is no acceleration in the *x* direction, and so the net force in the *x* direction must be 0. Write Newton's 2^{nd} law for the *x* direction.

$$
\sum F_x = F_{Ax} + F_{Bx} = 0 \rightarrow -F_A \sin 50^\circ + F_B \sin 30^\circ = 0 \rightarrow
$$

$$
F_B = \frac{F_A \sin 50^\circ}{\sin 30^\circ} = \frac{(4500 \text{ N}) \sin 50^\circ}{\sin 30^\circ} = \frac{6.9 \times 10^3 \text{ N}}{6.9 \times 10^3 \text{ N}}
$$

 Since the *x* components add to 0, the magnitude of the vector sum of the two forces will just be the sum of their *y* components.

$$
\sum F_y = F_{Ay} + F_{By} = F_A \cos 50^\circ + F_B \cos 30^\circ = (4500 \text{ N}) \cos 50^\circ + (6900 \text{ N}) \cos 30^\circ = 8.9 \times 10^3 \text{ N}
$$

28. Since all forces of interest in this problem are horizontal, draw the free-body diagram showing only the horizontal forces. \vec{F}_{T_1} is the tension in the coupling between the locomotive and the first car, and the first car, and it pulls to the right on the first car. \vec{F}_{T2} is the tension in the coupling between the first car an the second car. It pulls to the right on car 2, labeled \vec{F}_{T2R} and to the left on car 1, labeled \vec{F}_{T2L} . Both cars \rightarrow

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

have the same mass *m* and the same acceleration *a*. Note that $|\vec{F}_{T2R}| = |\vec{F}_{T2R}| = F_{T2}$ by Newton's 3rd law. \rightarrow

Write a Newton's $2nd$ law expression for each car.

$$
\sum F_1 = F_{T1} - F_{T2} = ma \qquad \sum F_2 = F_{T2} = ma
$$

Substitute the expression for *ma* from the second expression into the first one.

 $F_{T1} - F_{T2} = ma = F_{T2} \rightarrow F_{T1} = 2F_{T2} \rightarrow \boxed{F_{T1}/F_{T2} = 2}$

This can also be discussed in the sense that the tension between the locomotive and the first car is pulling 2 cars, while the tension between the cars is only pulling one car.

29. The window washer pulls down on the rope with her hands with a tension force F_{t} ,

so the rope pulls up on her hands with a tension force F_T . The tension in the rope is also applied at the other end of the rope, where it attaches to the bucket. Thus there is another force F_r pulling up on the bucket. The bucket-washer combination thus has a net force of $2F_r$ upwards. See the adjacent free-body diagram, showing only forces on the bucket-washer combination, not forces exerted by the combination (the pull down on the rope by the person) or internal forces (normal force of bucket on person).

(*a*) Write Newton's 2^{nd} law in the vertical direction, with up as positive. The net force must be zero if the bucket and washer have a constant speed.

$$
\sum F = F_{\rm T} + F_{\rm T} - mg = 0 \implies 2F_{\rm T} = mg \implies
$$

$$
F_{\rm T} = \frac{mg}{2} = \frac{(65 \text{ kg})(9.8 \text{ m/s}^2)}{2} = 320 \text{ N}
$$

(b) Now the force is increased by 15%, so $F_T = 320 \text{ N} (1.15) = 368 \text{ N}$. Again write Newton's 2nd law, but with a non-zero acceleration.

$$
\sum F = F_{\rm T} + F_{\rm T} - mg = ma \rightarrow
$$

$$
a = \frac{2F_{\rm T} - mg}{m} = \frac{2(368 \text{ N}) - (65 \text{ kg})(9.80 \text{ m/s}^2)}{65 \text{ kg}} = \boxed{1.5 \text{ m/s}^2}
$$

- 30. Since the sprinter exerts a force of 720 N on the ground at an angle of 22° below the horizontal, by Newton's 3^{rd} law the ground will exert a force of 720 N on the sprinter at an angle of 22° above the horizontal. A free-body diagram for the sprinter is shown.
	- (*a*) The horizontal acceleration will be found from the net horizontal force. Using Newton's 2nd law, we have the following.

$$
\sum F_x = F_p \cos 22^\circ = ma_x \rightarrow a_x = \frac{F_p \cos 22^\circ}{m} = \frac{(720 \text{ N}) \cos 22^\circ}{65 \text{ kg}}
$$

$$
= 10.27 \text{ m/s}^2 \approx \boxed{1.0 \times 10^1 \text{ m/s}^2}
$$

*m***g** G $\dot{\mathbf{F}}_{\rm N}$ $\overline{}$ $\hat{\mathbf{F}}_{\text{p}}$ \rightarrow 22°

© 2005 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

 $\dot{\mathbf{F}}_{\text{T}}$ $\overline{}$

*m***g** G

 $\dot{\mathbf{F}}_{\text{T}}$ \rightarrow

- - (*b*) Eq. 2-11a is used to find the final speed. The starting speed is 0.

$$
v = v_0 + at
$$
 $\rightarrow v = 0 + at = (10.27 \text{ m/s}^2)(0.32 \text{ s}) = 3.286 \text{ m/s} \approx 3.3 \text{ m/s}$

- 31. (*a*) See the free-body diagrams included.
	- (*b*) For block 1, since there is no motion in the vertical direction, we have $F_{N1} = m_1 g$. We write Newton's 2nd law for the *x* direction: $\sum F_{1x} = F_{\text{T}} = m_1 a_{1x}$. For block 2, we only need to consider vertical forces: $\sum F_{2y} = m_2 g - F_{\text{T}} = m_2 a_{2y}$. Since the two blocks are connected, the magnitudes of their accelerations will be the same, and so let $a_{1x} = a_{2y} = a$. Combine the two force equations from above, and solve for *a* by substitution.

$$
\vec{F}_{\text{N1}} \qquad \vec{F}_{\text{T}} \qquad \vec{F}_{\text{T}}
$$
\n
$$
m_1 \vec{g} \qquad \qquad \vec{F}_{\text{T}}
$$

$$
F_{\rm T} = m_1 a \qquad m_2 g - F_{\rm T} = m_2 a \qquad \rightarrow \qquad m_2 g - m_1 a = m_2 a \qquad \rightarrow
$$

$$
m_1 a + m_2 a = m_2 g \qquad \rightarrow \qquad a = g \frac{m_2}{m_1 + m_2} \qquad F_{\rm T} = m_1 a = g \frac{m_1 m_2}{m_1 + m_2}
$$

32. Consider a free-body diagram of the dice. The car is moving to the right. The acceleration of the dice is found from Eq. 2-11a.

$$
v = v_0 + a_x t
$$
 $\rightarrow a_x = \frac{v - v_0}{t} = \frac{28 \text{ m/s} - 0}{6.0 \text{ s}} = 4.67 \text{ m/s}^2$

Now write Newton's $2nd$ law for both the vertical (*y*) and horizontal (*x*) directions.

$$
\sum F_y = F_\text{T} \cos \theta - mg = 0 \rightarrow F_\text{T} = \frac{mg}{\cos \theta} \sum F_x = F_\text{T} \sin \theta = ma_x
$$

Substitute the expression for the tension from the *y* equation into the *x* equation.

$$
ma_x = F_{\rm T} \sin \theta = \frac{mg}{\cos \theta} \sin \theta = mg \tan \theta \implies a_x = g \tan \theta
$$

$$
\theta = \tan^{-1} \frac{a_x}{g} = \tan^{-1} \frac{4.67 \text{ m/s}^2}{9.8 \text{ m/s}^2} = 25^\circ
$$

33. (*a*) In the free-body diagrams below, \vec{F}_{12} = force on block 1 exerted by block 2, \vec{F}_{21} = force on block 2 exerted by block 1, \mathbf{F}_{23} = force on block 2 exerted by block 3, and \mathbf{F}_{32} = force on block 3 exerted by block 2. The magnitudes of \vec{F}_{21} and \vec{F}_{12} are equal, and the magnitudes of \vec{F}_{23} and \rightarrow 32 \rightarrow \vec{F}_{32} are equal, by Newton's 3rd law.

(b) All of the vertical forces on each block add up to zero, since there is no acceleration in the vertical direction. Thus for each block, $F_N = mg$. For the horizontal direction, we have

$$
\sum F = F - F_{12} + F_{21} - F_{23} + F_{32} = F = (m_1 + m_2 + m_3)a \rightarrow a = \frac{F}{m_1 + m_2 + m_3}
$$

(*c*) For each block, the net force must be *ma* by Newton's $2nd$ law. Each block has the same acceleration since they are in contact with each other.

(*d*) From the free-body diagram, we see that for m_3 , $F_{32} = F_{3net} = \frac{m_3}{\sqrt{3}}$ $1 + m_2 + m_3$ *net* $F_{32} = F_{3net} = \left| \frac{m_3 F}{m_1 + m_2 + m_3} \right|$. And by Newton's

 3^{rd} law, $F_{32} = F_{23} = F_{3\text{net}} = \frac{m_3 F}{\frac{1}{2}m_3 F}$ $1 + m_2 + m_3$ $F_{32} = F_{23} = F_{3net} = \frac{m_3 F}{m_1 + m_2 + m_3}$. Of course, \vec{F}_{23} and \vec{F}_{32} are in opposite directions.

Also from the free-body diagram, we see that for *m*1,

$$
F - F_{12} = F_{1net} = \frac{m_1 F}{m_1 + m_2 + m_3} \longrightarrow F_{12} = F - \frac{m_1 F}{m_1 + m_2 + m_3} \longrightarrow \left[F_{12} = \frac{(m_2 + m_3) F}{m_1 + m_2 + m_3} \right].
$$
 By

Newton's 3rd law, $F_{12} = F_{21} = \frac{(m_2 + m_3)}{m_2 + m_3}$ $_{12} - 1_{21}$ $1 + m_2 + m_3$ $m_2 + m_3$) F $F_{12} = F_{22}$ $= F_{21} = \left| \frac{(m_2 + m_3)F}{m_1 + m_2 + m_3} \right|.$

(*e*) Using the given values, $a = \frac{F}{\sqrt{1 - \frac{96.0 \text{ N}}{c}}}} = \sqrt{2.67 \text{ m/s}^2}$ $1 + m_2 + m_3$ $\frac{6.0 \text{ N}}{2.67 \text{ m/s}} = 2.67 \text{ m/s}$ 36.0 kg $a = \frac{F}{m_1 + m_2 + m_3} = \frac{96.0 \text{ N}}{36.0 \text{ kg}} = \left[\frac{2.67 \text{ m/s}^2}{2.67 \text{ m/s}^2} \right]$. Since all three masses

are the same value, the net force on each mass is $F_{net} = ma = (12.0 \text{ kg})(2.67 \text{ m/s}^2) = 32.0 \text{ N}$. This is also the value of F_{32} and F_{23} . The value of F_{12} and F_{21} is

$$
F_{12} = F_{21} = (m_2 + m_3) a = (24 \text{ kg})(2.67 \text{ m/s}^2) = 64.0 \text{ N}.
$$

To summarize:

$$
F_{\text{net 1}} = F_{\text{net 2}} = F_{\text{net 3}} = 32.0 \text{ N}
$$
 $F_{12} = F_{21} = 64.0 \text{ N}$ $F_{23} = F_{32} = 32.0 \text{ N}$

net force p ushing the entire set of blocks, *F*12 is the net force pushing the right two blocks, and *F*23 is The values make sense in that in order of magnitude, we should have $F > F_{21} > F_{32}$, since *F* is the the net force pushing the right block only.

First, draw a free-body diagram for each mass. Notice that the same 34. tension force is applied to each mass. Choo se UP to be the positive direction. Write Newton's $2nd$ law for each of the masses.

$$
F_{\rm T} - m_2 g = m_2 a_2 \qquad F_{\rm T} - m_1 g = m_1 a_1
$$

Since the masses are joined together by the cord, their accelerations will have the same magnitude but opposite directions. Thus $a_1 = -a_2$.

*m*² 2.2 kg *m*¹ 3.2 kg \vec{g} $\overrightarrow{m_1g}$ \vec{F}_{T} \vec{F}_{T} $m_2 \vec{g}$ *m*

Substitute this into the force expressions and solve for the acceleration by subtracting the second equation from the first.

$$
F_{\rm T} - m_1 g = -m_1 a_2 \rightarrow F_{\rm T} = m_1 g - m_1 a_2
$$

\n
$$
F_{\rm T} - m_2 g = m_2 a_2 \rightarrow m_1 g - m_1 a_2 - m_2 g = m_2 a_2 \rightarrow m_1 g - m_2 g = m_1 a_2 + m_2 a_2
$$

\n
$$
a_2 = \frac{m_1 - m_2}{m_1 + m_2} g = \frac{3.2 \text{ kg} - 2.2 \text{ kg}}{3.2 \text{ kg} + 2.2 \text{ kg}} (9.8 \text{ m/s}^2) = 1.815 \text{ m/s}^2
$$

The lighter block starts with a speed of 0, and moves a distance of 1.80 meters with the acceleration found above. Using Eq. 2-11c, the velocity of the lighter block at the end of this accelerated motion can be found.

$$
v^2 - v_0^2 = 2a(y - y_0) \rightarrow v = \sqrt{v_0^2 + 2a(y - y_0)} = \sqrt{0 + 2(1.815 \text{ m/s}^2)(1.80 \text{ m})} = 2.556 \text{ m/s}
$$

Now the lighter block has different conditions of motion. Once the heavier block hits the ground, speed will be 0. Eq. 2-11c can again be used to find the height to which it rises. the tension force disappears, and the lighter block is in free fall. It has an initial speed of 2.556 m/s upward as found above, with an acceleration of -9.8 m/s^2 due to gravity. At its highest point, its

$$
v^2 - v_0^2 = 2a(y - y_0)
$$
 $\rightarrow (y - y_0) = \frac{v^2 - v_0^2}{2a} = \frac{0 - (2.556 \text{ m/s})^2}{2(-9.8 \text{ m/s}^2)} = 0.33 \text{ m}$

Thus the total height above the ground is 1.80 m + 1.80 m + 0.33 m = $\overline{)3.93 \text{ m}}$.

 $F = 40.0 \text{ N}$ \longleftarrow 35. Please refer to the free-body diagrams given in the textbook for this problem. Initially, treat the two G boxes and the rope as a single system. Then the only accelerating force on the system is \mathbf{F}_{p} . The mass of the system is 23.0 kg, and so using Newton's $2nd$ law, the acceleration of the system is

$$
a = \frac{P_p}{m} = \frac{40.0 \text{ N}}{23.0 \text{ kg}} = \left[1.74 \text{ m/s}^2\right].
$$
 This is the acceleration of each piece of the system.

Now consider the left box alone. The only force on it is \mathbf{F}_{BT} , and it has the acceleration found above. Thus F_{BT} can be found from Newton's 2^{nd} law. \rightarrow

$$
F_{\text{BT}} = m_{\text{B}} a = (12.0 \text{ kg})(1.74 \text{ m/s}^2) = 20.9 \text{ N}.
$$

Now consider the rope alone. The net force on it is $\mathbf{F}_{T_A} - \mathbf{F}_{T_B}$, and it also has the acceleration fo above. Thus F_{TA} can be found from Newton's 2^{nd} law. $\overline{}$ und

$$
F_{\text{TA}} - F_{\text{TB}} = m_{\text{C}}a \rightarrow F_{\text{TA}} = F_{\text{TB}} + m_{\text{C}}a = 20.9 \text{ N} + (1.0 \text{ kg})(1.74 \text{ m/s}^2) = 22.6 \text{ N}
$$

A free-body diagram for the crate is shown. The crate does not accelerate 36. vertically, and so $F_{\text{N}} = mg$. The crate does not accelerate horizontally, and so $F_p = F_f$. Putting this together, we have

$$
F_{\rm p} = F_{\rm fr} = \mu_k F_{\rm N} = \mu_k mg = (0.30)(35 \text{ kg})(9.8 \text{ m/s}^2) = 103 = \boxed{1.0 \times 10^2 \text{ N}}
$$

F \rightarrow \rightarrow *m***g** $\overline{}$ N $\dot{\mathbf{F}}_{\text{fr}}$ $\vec{\mathbf{F}}_{\text{fr}}$ $\begin{bmatrix} \mathbf{f} & \mathbf{F}_{\text{N}} \ \hline \ \end{bmatrix}$ $\vec{\mathbf{F}}_{\text{p}}$

If the coefficient of kinetic friction is zero, then the horizontal force required is $[0 \text{ N}]$, since there is no friction to counteract. Of course, it woul d take a force to START the crate moving, but once it was moving, no further horizontal force would be necessary to maintain the motion.

37. A free-body diagram for the box is shown. Since the box does not accelerate vertically, $F_{N} = mg$

(*a*) To start the box moving, the pulling force must just overcome the force of static friction, and that means the force of static friction will reach its maximum value of $F_{f_r} = \mu_r F_N$. Thus we have for the starting motion,

F \rightarrow fr P **F** \rightarrow **F** $\overline{}$ $m\vec{g}$

$$
F_{\rm p} = F_{\rm fr} = \mu_s F_{\rm N} = \mu_s mg \rightarrow \mu_s = \frac{F_{\rm p}}{mg} = \frac{48.0 \text{ N}}{(5.0 \text{ kg})(9.8 \text{ m/s}^2)} = 0.98
$$

 (*b*) The same force diagram applies, but now the friction is kinetic friction, and the pulling force is NOT equal to the frictional force, since the box is accelerating to the right.

$$
\sum F = F_{p} - F_{f_{f}} = ma \rightarrow F_{p} - \mu_{k}F_{N} = ma \rightarrow F_{p} - \mu_{k}mg = ma \rightarrow
$$

$$
\mu_{k} = \frac{F_{p} - ma}{mg} = \frac{48.0 \text{ N} - (5.0 \text{ kg})(0.70 \text{ m/s}^{2})}{(5.0 \text{ kg})(9.8 \text{ m/s}^{2})} = \boxed{0.91}
$$

38. A free-body diagram for you as you stand on the train is shown. You do not accelerate vertically, and so $F_N = mg$. The maximum static frictional force is $\mu_s F_N$, and that must be greater than or equal to the force needed to accelerate you.

$$
F_{\text{fr}} \ge ma \rightarrow \mu_s F_{\text{N}} \ge ma \rightarrow \mu_s mg \ge ma \rightarrow \mu_s \ge a/g = 0.20g/g = 0.20
$$

The static coefficient of friction must be at least 0.20 for you to not slide.

39. A free-body diagram for the accelerating car is shown. The car does not accelerate vertically, and so $F_N = mg$. The static frictional force is the accelerating force, and so $F_f = ma$. If we assume the maximum acceleration, then we need the maximum force, and so the static frictional force would be its maximum value of $\mu_{s} F_{N}$. Thus we have

$$
Ffr = ma \rightarrow \mus FN = ma \rightarrow \mus mg = ma \rightarrow
$$

$$
a = \mus g = 0.80 (9.8 m/s2) = 7.8 m/s2
$$

40. See the included free-body diagram. To find the maximum angle, assume that the car is just ready to slide, so that the force of static friction is a maximum. Write Newton's $2nd$ law for both directions. Note that for both directions, the net force must be zero since the car is not accelerating.

$$
\sum F_y = F_N - mg \cos \theta = 0 \implies F_N = mg \cos \theta
$$

$$
\sum F_x = mg \sin \theta - F_{\text{fr}} = 0 \implies mg \sin \theta = F_{\text{fr}} = \mu_s F_N = \mu_s mg \cos \theta
$$

$$
\mu_s = \frac{mg \sin \theta}{mg \cos \theta} = \tan \theta = 0.8 \implies \theta = \tan^{-1} 0.8 = 39^\circ = 40^\circ \text{ (1 sig fig)}
$$

41. Start with a free-body diagram. Write Newton's $2nd$ law for each direction.

$$
\sum F_x = mg \sin \theta - F_{\text{fr}} = ma_x
$$

$$
\sum F_y = F_{\text{N}} - mg \cos \theta = ma_y = 0
$$

Notice that the sum in the *y* direction is 0, since there is no motion (and hence no acceleration) in the *y* direction. Solve for the force of friction.

$$
mg \sin \theta - F_{\text{fr}} = ma_x \rightarrow
$$

F_{\text{fr}} = mg \sin \theta - ma_x = (15.0 \text{ kg}) [(9.80 \text{ m/s}^2)(\sin 32^\circ) - 0.30 \text{ m/s}^2] = 73.40 \text{ N} \approx 73 \text{ N}

© 2005 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they Now solve for the coefficient of kinetic friction. Note that the expression for the normal force comes currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

from the *y* direction force equation above.

$$
F_{\text{fr}} = \mu_{\text{k}} F_{\text{N}} = \mu_{\text{k}} mg \cos \theta \rightarrow \mu_{\text{k}} = \frac{F_{\text{fr}}}{mg \cos \theta} = \frac{73.40 \text{ N}}{(15.0 \text{ kg})(9.80 \text{ m/s}^2)(\cos 32^\circ)} = \boxed{0.59}
$$

42. The direction of travel for the car is to the right, and that is also the positive horizontal direction. Using the free-body diagram, write Newton's $2nd$ law in the *x* direction for the car on the level road. We assume that the car is just on the verge of skidding, so that the magnitude of the friction force is $F_f = \mu_sF_N$.

$$
\sum F_x = -F_{\text{fr}} = ma
$$
 $F_{\text{fr}} = -ma = -\mu_s mg$ $\rightarrow \mu_s = \frac{a}{g} = \frac{4.80 \text{ m/s}^2}{9.80 \text{ m/s}^2} = 0.4898$

Now put the car on an inclined plane. Newton's $2nd$ law in the *x*-direction for the car on the plane is used to find the acceleration. We again assume the car is on the verge of slipping, so the static frictional force is at its maximum.

$$
\sum F_x = -F_{\text{fr}} - mg \sin \theta = ma \rightarrow \overline{F}_{\text{fr}}
$$

\n
$$
a = \frac{-F_{\text{fr}} - mg \sin \theta}{m} = \frac{-\mu_s mg \cos \theta - mg \sin \theta}{m} = -g(\mu_s \cos \theta + \sin \theta)
$$

\n
$$
= -(9.80 \text{ m/s}^2)(0.4898 \cos 13^\circ + \sin 13^\circ) = [-6.9 \text{ m/s}^2]
$$

 $\dot{\mathbf{F}}_{\text{fr}}$ $\overline{}$

> *m***g** G

 $\dot{\mathbf{F}}_{\rm N}$ \rightarrow

- 43. (*a*) Here is a free-body diagram for the box at rest on the plane. The force of friction is a STATIC frictional force, since the box is at rest.
	- (*b*) If the box were sliding down the plane, the only change is that the force of friction would be a KINETIC frictional force.
	- (*c*) If the box were sliding up the plane, the force of friction would be a KINETIC frictional force, and it would point down the plane, in the opposite direction to that shown in the diagram.
- 44. Assume that the static frictional force is the only force accelerating the racer. Then consider the free-body diagram for the racer as shown. It is apparent that \mathbf{F}_{N} the normal is equal to the weight, since there is no vertical acceleration. It is also assumed that the static frictional force is at its maximum. Thus

$$
F_f = ma \rightarrow \mu_s mg = ma \rightarrow \mu_s = a/g
$$

The acceleration of the racer can be calculated from Eq. 2-11b, with an initial speed of 0.

$$
x - x_0 = v_0 t + \frac{1}{2} a t^2 \rightarrow a = 2 (x - x_0) / t^2
$$

$$
\mu_s = \frac{a}{g} = \frac{2 (x - x_0)}{gt^2} = \frac{2 (1000 \text{ m})}{(9.8 \text{ m/s}^2) (12 \text{ sec})^2} = 1.4
$$

45. A free-body diagram for the bobsled is shown. The acceleration of the sled is found from Eq. 2-11c. The final velocity also needs to be converted to m/s.

$$
v = (60 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) = 16.667 \text{ m/s}
$$

© 2005 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is pr otected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without perm ission in writing from the publisher.

θ

$$
v^{2} - v_{0}^{2} = 2a_{x} (x - x_{0}) \rightarrow
$$

\n
$$
a_{x} = \frac{v^{2} - v_{0}^{2}}{2(x - x_{0})} = \frac{(16.667 \text{ m/s})^{2} - 0}{2(75 \text{ m})} = 1.852 \text{ m/s}^{2}
$$

Now write Newton's $2nd$ law for both directions. Since the sled does not accelerate in the *y* direction, the net force on the *y* direction must be 0. Then solve for the pushing force.

$$
\sum F_y = F_N - mg \cos \theta = 0 \rightarrow F_N = mg \cos \theta
$$

\n
$$
\sum F_x = mg \sin \theta + F_p - F_f = ma_x
$$

\n
$$
F_p = ma_x - mg \sin \theta + F_f = ma_x - mg \sin \theta + \mu_k F_N
$$

\n
$$
= ma_x - mg \sin \theta + \mu_k mg \cos \theta = m[a_x + g(\mu_k \cos \theta - \sin \theta)]
$$

\n
$$
= (22 \text{ kg})[1.852 \text{ m/s}^2 + (9.8 \text{ m/s}^2)(0.10 \cos 6.0^\circ - \sin 6.0^\circ)] = 39.6 \text{ N} \approx 40 \text{ N}
$$

46. The analysis of the blocks at rest can be done exactly the same as that presented in Example 4-20, up to the equation for the acceleration, $a = \frac{m_{II}S}{r}$ *I II* $a = \frac{m_{II}g - F_{I}}{g}$ $=\frac{m_{\mu}g-F_{\text{fr}}}{m_{\mu}+m_{\mu}}$. Now, for the stationary case, the force of friction is static friction. To find the minimum value of m_I , we assume the maximum static frictional force.

Thus $a = \frac{m_{II} s}{\sigma} \frac{\mu_s m_I}{\sigma}$ I ^{*I*} I *II* $m_{\mu}g - \mu_{\gamma}m_{\gamma}g$ $m_i + m$ $-\mu$ + . Finally, for the system to stay at rest, the acceleration must be zero. Thus

$$
m_{\mu}g - \mu_s m_{\mu}g = 0 \rightarrow m_{\mu} = m_{\mu}/\mu_s = 2.0 \text{ kg}/0.30 = 6.7 \text{ kg}
$$

47. A free-body diagram for the box is shown, assuming that it is moving to the right. The "push" is not shown on the free-body diagram because as soon as the box moves away from the source of the pushing force, the push is no longer applied to the box. It is apparent from the diagram that $F_N = mg$ for the vertical to the right, to find the acceleration of the box. direction. We write Newton's $2nd$ law for the horizontal direction, with positive

$$
\sum F_x = -F_{\text{fr}} = ma \rightarrow ma = -\mu_k F_{\text{N}} = -\mu_k mg \rightarrow
$$

$$
a = -\mu_k g = -0.2(9.8 \text{ m/s}^2) = -1.96 \text{ m/s}^2
$$

Eq. 2-11c can be used to find the distance that the box moves before stopping. T he initial speed is 4.0 m/s , and the final speed will be 0.

$$
v^2 - v_0^2 = 2a(x - x_0)
$$
 $\rightarrow x - x_0 = \frac{v^2 - v_0^2}{2a} = \frac{0 - (4.0 \text{ m/s})^2}{2(-1.96 \text{ m/s}^2)} = \boxed{4.1 \text{ m}}$

48. (*a*) Since the two blocks are in contact, they can be treated as a single object as long as no information is needed about internal forces (like the force of one block pushing on the other block). Since there is no motion in the vertical direction, it is apparent that $F_{_{\rm N}} = (m_{_{1}} + m_{_{2}}) g$, and so $F_{_{\rm fr}} = \mu_{_{k}} F_{_{\rm N}} = \mu_{_{k}} (m_{_{1}} + m_{_{2}}) g$. Write Newton's $2nd$ law for the horizontal direction. $\sum F_r = F_p - F_f = (m_1 + m_2) a \rightarrow$

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

 \overline{a}

 $\overline{}$

 $\dot{\mathbf{F}}_{\text{fr}}$ \rightarrow

 $\dot{\mathbf{F}}_{12}$ \rightarrow

$$
a = \frac{F_{\rm p} - F_{\rm fr}}{m_{\rm 1} + m_{\rm 2}} = \frac{F_{\rm p} - \mu_{\rm k} \left(m_{\rm 1} + m_{\rm 2} \right) g}{m_{\rm 1} + m_{\rm 2}} = \frac{620 \text{ N} - (0.15)(185 \text{ kg}) \left(9.8 \text{ m/s}^2 \right)}{185 \text{ kg}} = \boxed{1.9 \text{ m/s}^2}
$$

(*b*) To solve for the contact forces between the blocks, an individual block must be analyzed. Look at the free-body diagram for the second block. G \vec{F}_{21} is the force of the first block pushing on the second block. Again, it 2nd law for the horizontal direction. \rightarrow $\hat{\mathbf{F}}_{\text{fr2}}$ \overline{a} is apparent that $F_{N2} = m_2 g$ and so $F_{f_{N2}} = \mu_k F_{N2} = \mu_k m_2 g$. Write Newton's

 m_1 \vec{g}

*m***g** G

 $\dot{\mathbf{F}}_{\rm N}$ \rightarrow

$$
F_{21} = \mu_k m_2 g + m_2 a = (0.15)(110 \text{ kg})(9.8 \text{ m/s}^2) + (110 \text{ kg})(1.9 \text{ m/s}^2) = 3.7 \times 10^2 \text{ N}
$$

By Netwon's 3^{rd} law, there will also be a 370 N force to the left on block # 1 due to block # 2.

 (*c*) If the crates are reversed, the acceleration of the system will remain the same – the analysis from part (a) still applies. We can also repeat the simply change m_1 to m_2 in the free-body diagram and the resulting equations. The result would be analysis from part (b) to find the force of one block on the other, if we

 $\sum F_x = F_{21} - F_{\text{f}2} = m_2 a \rightarrow$

$$
F_{\text{fr1}} = \frac{1}{\mathbf{F}_{\text{N1}}} \int m_1 \vec{g} \, m_2 \, m \text{ in the free-body diagram and the resulting\n
$$
\sum F_x = F_{12} - F_{\text{fr1}} = m_1 a \rightarrow
$$
\n
$$
F_{12} = \mu_k m_1 g + m_1 a = (0.15)(75 \text{ kg})(9.8 \text{ m/s}^2) + (75 \text{ kg})(1.9 \text{ m/s}^2) = 2.5 \times 10^2 \text{ N}
$$
$$

49. The force of static friction is what decelerates the crate if it is not sliding on the truck bed. If the crate is not to slide, but the maximum deceleration is desired, then the maximum static frictional force must be exerted, and so $F_f = \mu_sF_N$.

The direction of travel is to the right. It is apparent that $F_N = mg$ since there is no acceleration in the *y* direction. Write Newton's $2nd$ law for the truck in the horizontal direction.

$$
\sum F_x = -F_{\text{fr}} = ma \rightarrow -\mu_s mg = ma \rightarrow a = -\mu_s g = -(0.75)(9.8 \text{ m/s}^2) = -7.4 \text{ m/s}^2
$$

The negative sign indicates the direction of the acceleration – opposite to the d irection of motion.

50. Consider a free-body diagram of the car on the icy inclined driveway. Assume that the car is not moving, but just ready to slip, so that the static frictional force has its maximum value of $F_f = \mu_s F_N$. Write Newton's 2nd law in each direction for the car, with a net force of 0 in each case.

$$
\sum F_y = F_N - mg \cos \theta = 0 \implies F_N = mg \cos \theta
$$

$$
\sum F_x = mg \sin \theta - F_{\text{fr}} = 0 \implies mg \sin \theta = \mu_s mg \cos \theta
$$

$$
\mu_s = \sin \theta / \cos \theta = \tan \theta \implies \theta = \tan^{-1} \mu_s = \tan^{-1} 0.15 = 8.5^\circ
$$

The car will not be able to stay at rest on any slope steeper than 8.5°.

Only the driveway across the street is safe for parking.

51. We assume that the child starts from rest at the top of the slide, and then slides a distance $x - x_0$ along the slide. A force diagram is shown for the child on the slide. First, ignore the frictional force and so consider the no-friction case. All of the motion is in the *x* direction, so we will only consider Newton's 2^{nd} law for the *x* direction.

$$
\sum F_x = mg\sin\theta = ma \rightarrow a = g\sin\theta
$$

Use Eq. 2-11c to calculate the speed at the bottom of the slide.

$$
v^{2} - v_{0}^{2} = 2a(x - x_{0}) \rightarrow v_{(No\text{ friction})} = \sqrt{v_{0}^{2} + 2a(x - x_{0})} = \sqrt{2g\sin\theta(x - x_{0})}
$$

Now include kinetic friction. We must consider Newton's $2nd$ law in both the *x* and *y* directions now. The net force in the γ direction must be 0 since there is no acceleration in the γ direction.

$$
\sum F_y = F_N - mg \cos \theta = 0 \implies F_N = mg \cos \theta
$$

$$
\sum F_x = ma = mg \sin \theta - F_E = mg \sin \theta - \mu_k F_N = mg \sin \theta - \mu_k mg \cos \theta
$$

$$
a = \frac{mg \sin \theta - \mu_k mg \cos \theta}{m} = g(\sin \theta - \mu_k \cos \theta)
$$

With this acceleration, we can again use Eq. 2-11c to find the speed after sliding a certain distance.

$$
v^{2} - v_{0}^{2} = 2a(x - x_{0}) \rightarrow v_{(\text{friction})} = \sqrt{v_{0}^{2} + 2a(x - x_{0})} = \sqrt{2g(\sin \theta - \mu_{k} \cos \theta)(x - x_{0})}
$$

Now let the speed with friction be half the speed without friction, and solve for the coefficient of friction. Square the resulting equation and divide by $g \cos \theta$ to get the result.

$$
v_{(\text{friction})} = \frac{1}{2} v_{(\text{No friction})} \rightarrow \sqrt{2g(\sin \theta - \mu_k \cos \theta)(x - x_0)} = \frac{1}{2} \sqrt{2g(\sin \theta)(x - x_0)}
$$

\n
$$
2g(\sin \theta - \mu_k \cos \theta)(x - x_0) = \frac{1}{4} 2g(\sin \theta)(x - x_0)
$$

\n
$$
\mu_k = \frac{3}{4} \tan \theta = \frac{3}{4} \tan 28^\circ = 0.40
$$

52. (*a*) Consider the free-body diagram for the carton on the surface. There is no motion in the *y* direction and thus no acceleration in the *y* direction. Write Newton's $2nd$ law for both directions.

$$
\sum F_x = F_N - mg \cos \theta = 0 \rightarrow F_N = mg \cos \theta
$$

\n
$$
\sum F_x = mg \sin \theta - F_{\text{fr}} = ma
$$

\n
$$
ma = mg \sin \theta - \mu_k F_N = mg \sin \theta - \mu_k mg \cos \theta
$$

\n
$$
a = g (\sin \theta - \mu_k \cos \theta)
$$

\n
$$
= (9.80 \text{ m/s}^2)(\sin 22.0^\circ - 0.12 \cos 22.0^\circ) = 2.58 = 2.6 \text{ m/s}^2
$$

(*b*) Now use Eq. 2-11c, with an initial velocity of 0, to find the final velocity.

$$
v^2 - v_0^2 = 2a(x - x_0)
$$
 $\rightarrow v = \sqrt{2a(x - x_0)} = \sqrt{2(2.58 \text{ m/s}^2)(9.30 \text{ m})} = 6.9 \text{ m/s}$

53. (*a*) Consider the free-body diagram for the carton on the frictionless surface. There is no acceleration in the *y* direction. Write Newton's 2nd law for the *x* direction.

$$
\sum F_x = mg \sin \theta = ma \rightarrow a = g \sin \theta
$$

Use Eq. 2-11c with $v_0 = -3.0 \text{ m/s}$ and $v = 0 \text{ m/s}$ to find the distance that it slides before stopping.

$$
v^{2} - v_{0}^{2} = 2a(x - x_{0}) \rightarrow
$$

$$
(x - x_{0}) = \frac{v^{2} - v_{0}^{2}}{2a} = \frac{0 - (-3.0 \text{ m/s})^{2}}{2(9.8 \text{ m/s}^{2}) \sin 22.0^{\circ}} = \boxed{-1.2 \text{ m}}
$$

The negative sign means that the block is displaced up the plane, which is the negative direction.

(*b*) The time for a round trip can be found from Eq. 2-11a. The free-body diagram (and thus the acceleration) is the same whether the block is rising or falling. For the entire trip, $v_0 = -3.0 \text{ m/s}$

and
$$
v = +3.0 \text{ m/s}
$$
.

$$
v = v_0 + at
$$
 \rightarrow $t = \frac{v - v_0}{a} = \frac{(3.0 \text{ m/s}) - (-3.0 \text{ m/s})}{(9.8 \text{ m/s}^2) \sin 22^\circ} = 1.6 \text{ s}$

54. See the free-body diagram for the descending roller coaster. It starts its

descent with $v_0 = (6.0 \text{ km/h}) \left(\frac{1 \text{ m/s}}{2.61 \text{ m/s}} \right) = 1.667 \text{ m/s}$ $v_0 = (6.0 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) =$. The total

second law for both the *x* and *y* directions. displacement in the *x* direction is $x - x_0 = 45.0$ m. Write Newton's

$$
\sum F_y = F_N - mg \cos \theta = 0 \implies F_N = mg \cos \theta
$$

$$
\sum F_x = ma = mg \sin \theta - F_{\text{fr}} = mg \sin \theta - \mu_k F_N = mg \sin \theta - \mu_k mg \cos \theta
$$

$$
a = \frac{mg \sin \theta - \mu_k mg \cos \theta}{m} = g(\sin \theta - \mu_k \cos \theta)
$$

Now use Eq. 2-11c to solve for the final velocity.

$$
v^{2} - v_{0}^{2} = 2a(x - x_{0}) \rightarrow
$$

\n
$$
v = \sqrt{v_{0}^{2} + 2a(x - x_{0})} = \sqrt{v_{0}^{2} + 2g(\sin \theta - \mu_{k} \cos \theta)(x - x_{0})}
$$

\n
$$
= \sqrt{(1.667 \text{ m/s})^{2} + 2(9.8 \text{ m/s}^{2})[\sin 45^{\circ} - (0.18) \cos 45^{\circ}](45.0 \text{ m})}
$$

\n= 22.68 m/s $\approx \sqrt{23 \text{ m/s}} \approx 82 \text{ km/h}$

55. Consider a free-body diagram of the box. Write Newton's $2nd$ law for both directions. The net force in the *y* direction is 0 because there is no acceleration in the *y* direction. *y*

$$
\sum F_y = F_N - mg \cos \theta = 0 \implies F_N = mg \cos \theta
$$

$$
\sum F_x = mg \sin \theta - F_{\text{fr}} = ma
$$

Now solve for the force of frict ion and the coefficient of friction.

$$
\sum F_y = F_N - mg \cos \theta = 0 \rightarrow F_N = mg \cos \theta
$$

\n
$$
\sum F_x = mg \sin \theta - F_{\text{fr}} = ma
$$

\n
$$
F_{\text{fr}} = mg \sin \theta - ma = m (g \sin \theta - a) = (18.0 \text{ kg}) [(9.80 \text{ m/s}^2)(\sin 37.0^\circ) - 0.270 \text{ m/s}^2]
$$

\n= 101.3 N \approx 101 N

F_{\text{fr}} = \mu_{\text{k}} F_{\text{N}} = \mu_{\text{k}} mg \cos \theta \rightarrow \mu_{\text{k}} = \frac{F_{\text{fr}}}{mg \cos \theta} = \frac{101.3 \text{ N}}{(18.0 \text{ kg})(9.80 \text{ m/s}^2)\cos 37.0^{\circ}} = \boxed{0.719}
$$

56. Consider a free-body diagram for the box, showing force on the box. When $F_p = 13$ N, the block does not move. Thus in that case, the force of friction is static friction, and must be at its maximum value, given by $F_f = \mu_s F_N$. case must be 0, since the block is at rest. Write Newton's 2^{nd} law in both the *x* and *y* directions. The net force in each

$$
\sum F_x = F_p \cos \theta - F_N = 0 \rightarrow F_N = F_p \cos \theta
$$

\n
$$
\sum F_y = F_{fr} + F_p \sin \theta - mg = 0 \rightarrow F_{fr} + F_p \sin \theta = mg
$$

\n
$$
\mu_s F_N + F_p \sin \theta = mg \rightarrow \mu_s F_p \cos \theta + F_p \sin \theta = mg
$$

\n
$$
m = \frac{F_p}{g} (\mu_s \cos \theta + \sin \theta) = \frac{13 \text{ N}}{9.80 \text{ m/s}^2} (0.40 \cos 28^\circ + \sin 28^\circ) = 1.1 \text{ kg}
$$

57. (*a*) Consider the free-body diagram for the snow on the roof. If the snow is just ready to slip, then the static frictional force is at its maximum value, $F_{\text{fr}} = \mu_s F_{\text{N}}$. Write Newton's 2nd law in both directions, with the net force equal to zero since the snow is not accelerating.

$$
\sum F_y = F_N - mg \cos \theta = 0 \rightarrow F_N = mg \cos \theta
$$
\n
$$
\sum F_x = mg \sin \theta - F_{\text{fr}} = 0 \rightarrow
$$
\n
$$
mg \sin \theta = F_{\text{fr}} = \mu_s F_N = \mu_s mg \cos \theta \rightarrow \mu_s = \tan \theta = \tan 30^\circ = 0.58
$$

(*b*) The same free-body diagram applies for the sliding snow. But now the force of friction is kinetic, so $F_{\text{fr}} = \mu_k F_{\text{N}}$, and the net force in the *x* direction is not zero. Write Newton's 2nd law for the *x* direction again, and solve for the acceleration.

$$
\sum F_x = mg \sin \theta - F_{\text{fr}} = ma
$$

$$
a = \frac{mg \sin \theta - F_{\text{fr}}}{m} = \frac{mg \sin \theta - \mu_k mg \cos \theta}{m} = g \left(\sin \theta - \mu_k \cos \theta \right)
$$

Use Eq. 2-11c with $v_i = 0$ to find the speed at the end of the roof.

$$
v^{2} - v_{0}^{2} = 2a(x - x_{0})
$$

\n
$$
v = \sqrt{v_{0} + 2a(x - x_{0})} = \sqrt{2g(\sin \theta - \mu_{k} \cos \theta)(x - x_{0})}
$$

\n
$$
= \sqrt{2(9.8 \text{ m/s}^{2})(\sin 30^{\circ} - (0.20)\cos 30^{\circ})(5.0 \text{ m})} = 5.66 = 5.7 \text{ m/s}
$$

(*c*) Now the problem becomes a projectile motion problem. The projectile has an initial speed of 5.7 m/s, directed at an angle of 30° below the horizontal. The horizontal component of the speed, $(5.66 \text{ m/s}) \cos 30^\circ =$ 4.90 m/s, will stay constant. The vertical component will change due to vertical velocity is (5.66 m/s) sin 30^o = 2.83 m/s, the vertical acceleration is 9.8 m/s², and the vertical displacement is 10.0 m. Use Eq. 2-11c to find the final vertical speed. gravity. Define the positive direction to be downward. Then the starting 30°

$$
v_y^2 - v_{y0y}^2 = 2a(y - y_0)
$$

$$
v_y = \sqrt{v_{y0}^2 + 2a(y - y_0)} = \sqrt{(2.83 \text{ m/s})^2 + 2(9.8 \text{ m/s}^2)(10.0 \text{ m})} = 14.3 \text{ m/s}
$$

To find the speed when it hits the ground, the horizontal and vertical components of velocity must again be combined, according to the Pythagorean theorem.

$$
v = \sqrt{v_x^2 + v_y^2} = \sqrt{(4.90 \text{ m/s})^2 + (14.3 \text{ m/s})^2} = 15 \text{ m/s}
$$

58. (*a*) A free-body diagram for the car is shown, assuming that it is moving to the right. It is apparent from the diagram that $F_N = mg$ for the vertical direction. Write Newton's 2nd law for the horizontal direction, with positive to the right, to find the acceleration of the car. Since the car is assumed to NOT be sliding, use the maximum force of static friction.

$$
\overbrace{\text{S}_{\text{fr}}\left(\text{S}_{\text{fr}}\right)}^{\overbrace{\text{F}_{\text{N}}}}_{\text{m}\overline{\text{g}}}
$$

 \rightarrow

$$
\sum F_x = -F_{\text{fr}} = ma \rightarrow ma = -\mu_s F_{\text{N}} = -\mu_s mg \rightarrow a = -\mu_s g
$$

Eq. 2-11c can be used to find the distance that the car moves before stopping. The initial speed is given as *v*, and the final speed will be 0.

$$
v^2 - v_0^2 = 2a(x - x_0) \rightarrow (x - x_0) = \frac{v^2 - v_0^2}{2a} = \frac{0 - v^2}{2(-\mu_s g)} = \frac{v^2}{2\mu_s g}
$$

(*b*) Using the given values:

$$
v = (95 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) = 26.38 \text{ m/s} \qquad (x - x_0) = \frac{v^2}{2\mu_s g} = \frac{(26.38 \text{ m/s})^2}{2(0.75)(9.8 \text{ m/s}^2)} = \boxed{47 \text{ m}}
$$

59. A free-body diagram for the coffee cup is shown. Assume that the car is moving to the right, and so the acceleration of the car (and cup) will be to the left. The the cup to not slide on the dash, and to have the minimum deceleration time means deceleration of the cup is caused by friction between the cup and the dashboard. For the largest possible static frictional force is acting, so $F_f = \mu_sF_N$. The normal force

*m***g** $\ddot{}$ $\dot{\mathbf{F}}_{\rm N}$ \rightarrow $\dot{\mathbf{F}}_{\text{fr}}$

x

θ θ *m***g** $\overline{}$

 $\dot{\mathbf{F}}_{\rm fr}$

 $\dot{\mathbf{F}}_{\rm N}$ \rightarrow

on the cup is equal to its weight, since there is no vertical acceleration. The horizontal acceleration of the cup is found from Eq. 2-11a, with a final velocity of zero.

$$
v_0 = (45 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) = 12.5 \text{ m/s}
$$

$$
v - v_0 = at \rightarrow a = \frac{v - v_0}{t} = \frac{0 - 12.5 \text{ m/s}}{3.5 \text{ s}} = -3.57 \text{ m/s}^2
$$

Write Newton's $2nd$ law for the horizontal forces, considering to the right to be positive.

$$
\sum F_x = -F_{\text{fr}} = ma \rightarrow ma = -\mu_s F_{\text{N}} = -\mu_s mg \rightarrow \mu_s = -\frac{a}{g} = -\frac{\left(-3.57 \text{ m/s}^2\right)}{9.80 \text{ m/s}^2} = \boxed{0.36}
$$

60. We derive two expressions for acceleration – one from the kinematics, and one from the dynamics. From Eq. 2-11c with a starting speed of v_0 up the plane and a final speed of zero, we have

$$
v^2 - v_o^2 = 2a(x - x_o)
$$
 $\rightarrow a = \frac{-v_o^2}{2(x - x_o)} = \frac{-v_o^2}{2d}$
Write Newton's $2nd$ law for both the *x* and *y* directions. Note that the net force in the *y* direction is zero, since the block does not accelerate in the *y* direction.

$$
\sum F_y = F_N - mg \cos \theta = 0 \implies F_N = mg \cos \theta
$$

$$
\sum F_x = -mg \sin \theta - F_{\text{fr}} = ma \implies a = \frac{-mg \sin \theta - F_{\text{fr}}}{m}
$$

Now equate the two expressions for the acceleration, substitute in the relationship between the frictional force and the normal force, and solve for the coefficient of friction.

$$
a = \frac{-mg\sin\theta - F_{\text{fr}}}{m} = \frac{-v_o^2}{2d} \rightarrow \frac{mg\sin\theta + \mu_k mg\cos\theta}{m} = \frac{v_o^2}{2d} \rightarrow \frac{1}{2gd\cos\theta} = \frac{v_o^2}{2gd\cos\theta} = \frac{1}{2gd} \rightarrow \frac{1}{2gd\cos\theta}
$$

61. Since the walls are vertical, the normal forces are horizontal, away from the wall faces. We assume that the frictional forces are at their maximum values, so $F_f = \mu_s F_N$ applies at each wall. We assume that the rope in the diagram is not under any tension and so does not exert any forces. Consider the free-body diagram for the climber. F_{NR} is the normal force on the climber from the right

wall, and F_{NL} is the normal force on the climber from the left wall. The static frictional forces are $F_{\text{fit}} = \mu_{sL} F_{\text{NL}}$ and $F_{\text{frR}} = \mu_{sR} F_{\text{NR}}$. Write Newton's 2nd law for both the *x* and *y* directions. The net force in each direction must be zero if the climber is stationary.

$$
\sum F_x = F_{\text{NL}} - F_{\text{NR}} = 0 \implies F_{\text{NL}} = F_{\text{NR}} \qquad \sum F_y = F_{\text{fit}} + F_{\text{frR}} - mg = 0
$$

Substitute the information from the *x* equation into the *y* equation.

$$
F_{\text{frl.}} + F_{\text{ffr.}} = mg \rightarrow \mu_{sL} F_{\text{NL}} + \mu_{sR} F_{\text{NR}} = mg \rightarrow (\mu_{sL} + \mu_{sR}) F_{\text{NL}} = mg
$$

$$
F_{\text{NL}} = \frac{mg}{(\mu_{sL} + \mu_{sR})} = \frac{(75 \text{ kg})(9.80 \text{ m/s}^2)}{1.4} = 525 \text{ N}
$$

And so $F_{NL} = F_{NR} = 525$ N. These normal forces arise as Newton's 3rd law reaction forces to the each wall. climber pushing on the walls. Thus the climber must exert a force of at least 5.3×10^2 N against

62. Notice the symmetry of this problem $-$ in the first half of the motion, the object accelerates with a constant acceleration to a certain speed, and then in the second half of the motion, the object decelerates with the same magnitude of acceleration back to a speed of 0. Half the time elapses during the first segment of the motion, and half the distance is traveled during the first segment of the motion. Thus we analyze half of the motion, and then double the time found to get the total time.

Friction is the accelerating and decelerating force. We assume that the boxes do not slip on the belt since slippage would increase the travel time. To have the largest possible acceleration, and hence the largest possible force, so that the travel time can be a minimum, the box must be moved by the maximum value of the static frictional force, and so $F_f = \mu_sF_N$. See the free-body diagram for the box on the first half of the trip, assuming that the conveyor belt is level. Since there is no vertical

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

acceleration of the box, it is apparent that $F_N = mg$, and so $F_f = \mu_s mg$. Use Newton's 2nd law in the horizontal direction to find the acceleration.

$$
\sum F = F_{\text{fr}} = \mu_s mg = ma \rightarrow a = \mu_s g = (0.60)(9.8 \text{ m/s}^2) = 5.88 \text{ m/s}^2
$$

Now use Eq. 2-11b to determine the time taken to move half the distance with the calculated acceleration, starting from rest.

$$
d/2 = x - x_0 = v_0 t + \frac{1}{2} a t^2 \rightarrow t = \sqrt{d/a}.
$$

Thus the total time for the trip will be $t_{\text{total}} = 2\sqrt{d/a} = 2\sqrt{(11.0 \text{ m})/(5.88 \text{ m/s}^2)} = 2.7 \text{ s}$

63. (*a*) Draw a free-body diagram for each block. Write Newton's $2nd$ law for each block. Notice that the acceleration of block $# 1$ in the y_1 direction will be zero, since it has no motion in the y_1 direction. $\sum F_{y1} = F_{\text{N}} - m_1 g \cos \theta = 0 \rightarrow F_{\text{N}} = m_1 g \cos \theta$ $\dot{\mathbf{F}}_{\text{T}}$ $\overline{}$ $\dot{\mathbf{F}}_{\rm N}$ \mathbf{F}_{T} \mathbf{Z} \rightarrow *y1 y2*

$$
\sum F_{y1} = F_N - m_1 g \cos \theta = 0 \rightarrow F_N = m_1 g \cos \theta
$$
\n
$$
\sum F_{x1} = m_1 g \sin \theta - F_T = m_1 a_{x1}
$$
\n
$$
\sum F_{y2} = F_T - m_2 g = m_2 a_{y2} \rightarrow F_T = m_2 (g + a_{y2})
$$
\n
$$
m_1 g
$$

Since the blocks are connected by the cord, $a_{v2} = a_{x1} = a$. Substitute the expression for the tension force from the last equation into the *x* direction equation for block 1, and solve for the acceleration.

$$
m_1 g \sin \theta - m_2 (g + a) = m_1 a \rightarrow m_1 g \sin \theta - m_2 g = m_1 a + m_2 a
$$

$$
a = \frac{g \left(m_1 \sin \theta - m_2 \right)}{(m_1 + m_2)}
$$

- $m_1 \sin \theta > m_2$ (down the plane). The acceleration will be up the plane (negative) if (*b*) If the acceleration is to be down the plane, it must be positive. That will happen if $m_1 \sin \theta < m_2$ (up the plane). If $m_1 \sin \theta = m_2$, then the system will not accelerate. It will move with a constant speed if set in motion by a push.
- 64. *(a)* Given that m_2 is moving down, m_1 must be moving up the incline, and so the force of kinetic friction on m_1 will be directed down the incline. Since the blocks are tied together, they will both have the same acceleration, and so $a_{v2} = a_{x1} = a$. Write Newton's $2nd$ law for each mass.

$$
\sum F_{y2} = mg - F_{\text{T}} = ma \rightarrow F_{\text{T}} = mg - ma
$$

$$
\sum F_{x1} = F_{\text{T}} - mg \sin \theta - F_{\text{fr}} = ma
$$

$$
\sum F_{y1} = F_{\text{N}} - mg \cos \theta = 0 \rightarrow F_{\text{N}} = mg \cos \theta
$$

Take the information from the two *y* equations and substitute into the *x* equation to solve for the acceleration.

 $mg - ma - mg\sin\theta - \mu_k mg\cos\theta = ma$

$$
a = g \frac{\left(1 - \sin \theta - \mu_k \cos \theta\right)}{2} = \left(9.8 \,\mathrm{m/s^2}\right) \frac{\left(1 - \sin 25^\circ - 0.15 \cos 25^\circ\right)}{2} = \boxed{2.2 \,\mathrm{m/s^2}}
$$

(*b*) To have an acceleration of zero, the expression for the acceleration must be zero.

$$
a = g \frac{(1 - \sin \theta - \mu_k \cos \theta)}{2} = 0 \implies 1 - \sin \theta - \mu_k \cos \theta = 0 \implies
$$

$$
\mu_k = \frac{1 - \sin \theta}{\cos \theta} = \frac{1 - \sin 25^{\circ}}{\cos 25^{\circ}} = 0.64
$$

65. Consider a free-body diagram for the cyclist coasting downhill at a constant speed. Since there is no acceleration, the net force in each direction must be zero. Write Newton's $2nd$ law for the *x* direction.

$$
\sum F_x = mg \sin \theta - F_{\text{fr}} = 0 \rightarrow F_{\text{fr}} = mg \sin \theta
$$

This establishes the size of the air friction force at 6.0 km/h, and so can be used in the next part.

Now consider a free-body diagram for the cyclist climbing the hill. F_{p} is the force pushing the cyclist uphill. Again, write Newton's $2nd$ law for the *x* direction, with a net force of 0.

$$
\sum F_x = F_{\text{fr}} + mg \sin \theta - F_{\text{p}} = 0 \rightarrow
$$

\n
$$
F_{\text{p}} = F_{\text{fr}} + mg \sin \theta = 2mg \sin \theta
$$

\n
$$
= 2(65 \text{ kg})(9.8 \text{ m/s}^2)(\sin 6.0^\circ) = 1.3 \times 10^2 \text{ N}
$$

66. The average acceleration of the blood is given by $a = \frac{v - v_0}{\frac{v_0}{s}} = \frac{0.35 \text{ m/s} - 0.25 \text{ m/s}}{1.0 \text{ m/s}^2} = 1.0 \text{ m/s}^2$ 0.10 s $a = \frac{v - v}{v}$ *t* $=\frac{v-v_0}{v}=\frac{0.35 \text{ m/s}-0.25 \text{ m/s}}{0.25 \text{ m/s}}=1.0 \text{ m/s}^2$. Thus the net force on the blood, exerted by the heart, would be

$$
F = ma = (20 \times 10^{-3} \text{kg})(1.0 \text{ m/s}^2) = 0.020 \text{ N}.
$$

67. The acceleration of a person having a 30 "*g*" deceleration is $a = (30" g") \left(\frac{9.8 \text{ m/s}^2}{" g" } \right) = 290 \text{ m/s}^2$.

The average force causing that acceleration is $F = ma = (70 \text{ kg})(290 \text{ m/s}^2) = 2.1 \times 10^4 \text{ N}$. Since

the person is undergoing a deceleration, the acceleration and force would both be directed opposite to the direction of motion. Use Eq. 2-11c to find the distance traveled during the deceleration. Take the initial velocity to be in the positive direction, so that the acceleration will have a negative value, and the final velocity will be 0.

$$
v_0 = (100 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) = 27.78 \text{ m/s}
$$

$$
v^2 - v_0^2 = 2a(x - x_0) \rightarrow (x - x_0) = \frac{v^2 - v_0^2}{2a} = \frac{0 - (27.78 \text{ m/s})^2}{2(-290 \text{ m/s}^2)} = 1.3 \text{ m}
$$

68. (*a*) Assume that the earthquake is moving the Earth to the right. If an object is to "hold its place", then the object must also be accelerating to the right with the Earth. The force that will accelerate that object will be the static frictional force, which would also have to be to the right. If the force were not large enough, the Earth would move out from under the chair somewhat, giving the appearance that the chair were being "thrown" to the left. Consider the free-

body diagram shown for a chair on the floor. It is apparent that the normal force is equal to the weight since there is no motion in the vertical direction. Newton's 2^{nd} law says that $\hat{F}_{\hat{F}} = ma$.

We also assume that the chair is just on the verge of slipping, which means that the static frictional force has its maximum value of $F_f = \mu_s F_N = \mu_s mg$. Equate the two expressions for the frictional force to find the coefficient of friction.

$$
ma = \mu_s mg \rightarrow \boxed{\mu_s = a/g}
$$

If the static coefficient is larger than this, then there will be a larger maximum frictional force, and the static frictional force will be more than sufficient to hold the chair in place on the floor.

(b) For the 1989 quake,
$$
\frac{a}{g} = \frac{4.0 \text{ m/s}^2}{9.8 \text{ m/s}^2} = 0.41
$$
. Since $\mu_s = 0.25$, the chair would slide.

69. We draw three free-body diagrams – one for the car, one for the trailer, and then "add" them for the combination of car and trailer. Note that since the car pushes against the ground, the ground will push against the car with an Equal but oppositely directed force. \vec{F}_{CG} is the force on the car due to the ground, \vec{F}_{TC} is the force on the trailer due to the car, and \vec{F}_{CT} is the force on the car due to the trailer. Note that by Newton's 3rd law, $|\vec{F}_{CT}| = |\vec{F}_{TC}|$.

From consideration of the vertical forces in the individual free-body diagrams, it is apparent that the normal force on each object is equal to its weight. This leads to the conclusion that

$$
F_{\text{fr}} = \mu_{k} F_{\text{NT}} = \mu_{k} m_{\text{T}} g = (0.15)(450 \text{ kg})(9.8 \text{ m/s}^{2}) = 660 \text{ N}.
$$

Now consider the combined free-body diagram. Write Newton's $2nd$ law for the horizontal direction, This allows the calculation of the acceleration of t he system.

$$
\sum F = F_{\text{CG}} - F_{\text{fr}} = (m_{\text{C}} + m_{\text{T}}) a \rightarrow
$$

$$
a = \frac{F_{\text{CG}} - F_{\text{fr}}}{m_{\text{C}} + m_{\text{T}}} = \frac{3800 \text{ N} - 660 \text{ N}}{1600 \text{ kg}} = 1.9625 \text{ m/s}^2
$$

 $(m_{\rm C} + m_{\rm T})\vec{g}$ $\vec{F}_{NT} + \vec{F}_{NC}$ $\vec{F}_{MC} + m_T \vec{g}$ $\overline{}$ $\dot{\mathbf{F}}_\text{CG}$ \rightarrow $\dot{\mathbf{F}}_{\text{fr}}$ \rightarrow

Finally, consider the free-body diagram for the trailer alone. Again write Newton's $2nd$ law for the horizontal direction, and solve for F_{TC} .

$$
\sum F = F_{\text{TC}} - F_{\text{fr}} = m_{\text{T}} a \rightarrow
$$

F_{\text{TC}} = F_{\text{fr}} + m_{\text{T}} a = 660 \text{ N} + (450 \text{ kg})(1.9625 \text{ m/s}^2) = 1.54 \times 10^3 \text{ N}

 $\dot{\mathbf{F}}_{\text{fr}}$ \rightarrow

-
- 70. Assume that kinetic friction is the net force causing the deceleration. See the free-body diagram for the car, assuming that the right is the positive direction, and the direction of motion of the skidding car. Since there is no acceleration in the vertical direction, and so $F_N = mg$. Applying Newton's 2nd law to the *x* direction gives

$$
\sum F = -F_f = ma \rightarrow -\mu_k F_{N} = -\mu_k mg = ma \rightarrow a = -\mu_k g.
$$

Use Eq. 2-11c to determine the initial speed of the car, with the final speed of the car being zero. $x^2 - v_0^2 = 2a(x - x_0)$ $v^2 - v_0^2 = 2a(x - x_0) \rightarrow$

$$
v_0 = \sqrt{v^2 - 2a(x - x_0)} = \sqrt{0 - 2(-\mu_k g)(x - x_0)} = \sqrt{2(0.8)(9.8 \text{ m/s}^2)(72 \text{ m})} = \sqrt{34 \text{ m/s}}
$$

71. We include friction from the start, and then for the no-friction result, set the coefficient of friction equal to 0. Consider a free-body diagram for the car on the hill. Write Newton's $2nd$ law for both directions. Note that the net force on the *y* direction will be zero, since there is no acceleration in the *y* direction.

$$
\sum F_y = F_N - mg \cos \theta = 0 \rightarrow F_N = mg \cos \theta
$$

$$
\sum F_x = mg \sin \theta - F_{\text{fr}} = ma \rightarrow
$$

$$
a = g \sin \theta - \frac{F_{\text{fr}}}{m} = g \sin \theta - \frac{\mu_k mg \cos \theta}{m} = g (\sin \theta - \mu_k \cos \theta)
$$

Use Eq. 2-11c to determine the final velocity, assuming that the car starts from rest.

$$
v^2 - v_0^2 = 2a(x - x_0) \rightarrow v = \sqrt{0 + 2a(x - x_0)} = \sqrt{2g(x - x_0)(\sin \theta - \mu_k \cos \theta)}
$$

The angle is given by $\sin \theta = 1/4 \rightarrow \theta = \sin^{-1} 0.25 = 14.5^{\circ}$

(a)
$$
\mu_k = 0 \rightarrow \nu = \sqrt{2g(x - x_0)x\sin\theta} = \sqrt{2(9.8 \text{ m/s}^2)(55 \text{ m})\sin 14.5^\circ} = \boxed{16 \text{ m/s}}
$$

(b) $\mu_k = 0.10 \rightarrow \nu = \sqrt{2(9.8 \text{ m/s}^2)(55 \text{ m})(\sin 14.5^\circ - 0.10 \cos 14.5^\circ)} = \boxed{13 \text{ m/s}}$

72. See the free-body diagram for the falling purse. Assume that down is the positive G direction, and that the air resistance force \vec{F}_{fr} is constant. Write Newton's 2nd law for the vertical direction.

$$
\sum F = mg - F_{\text{fr}} = ma \rightarrow F_{\text{fr}} = m(g - a)
$$

Now obtain an expression for the acceleration from Eq. 2-11c with $v_0 = 0$, and substitute back into the friction force.

$$
v^{2} - v_{0}^{2} = 2a(x - x_{0}) \rightarrow a = \frac{v^{2}}{2(x - x_{0})}
$$

$$
F_{f} = m\left(g - \frac{v^{2}}{2(x - x_{0})}\right) = (2.0 \text{ kg})\left(9.8 \text{ m/s}^{2} - \frac{(29 \text{ m/s})^{2}}{2(55 \text{ m})}\right) = \boxed{4.3 \text{ N}}
$$

 $\frac{1}{mg}$

*m***g** G

 $\dot{\mathbf{F}}_{\rm fr}$ \rightarrow

 $\dot{\mathbf{F}}_{\rm N}$ \rightarrow

-
- 73. Consider the free-body diagram for the cyclist in the mud, assuming that the cyclist is traveling to the right. It is apparent that $F_N = mg$ since there is no vertical acceleration. Write Newton's $2nd$ law for the horizontal direction, positive to the right.

$$
\sum F_x = -F_{\text{fr}} = ma \rightarrow -\mu_k mg = ma \rightarrow a = -\mu_k g
$$

Use Eq. 2-11c to determine the distance the cyclist could travel in the mud before coming to rest.

$$
v^{2} - v_{0}^{2} = 2a(x - x_{0}) \rightarrow (x - x_{0}) = \frac{v^{2} - v_{0}^{2}}{2a} = \frac{-v_{0}^{2}}{-2\mu_{k}g} = \frac{(12 \text{ m/s})^{2}}{2(0.60)(9.8 \text{ m/s}^{2})} = 12 \text{ m}
$$

Since there is only 11 m of mud, the cyclist will emerge from the mud. The speed upon emerging is found from Eq. 2-11c.

$$
v^{2} - v_{0}^{2} = 2a(x - x_{0}) \rightarrow
$$

\n
$$
v = \sqrt{v_{0}^{2} + 2a(x - x_{0})} = \sqrt{v_{i}^{2} - 2\mu_{k}g(x - x_{0})} = \sqrt{(12 \text{ m/s})^{2} - 2(0.60)(9.8 \text{ m/s}^{2})(11 \text{ m})}
$$

\n
$$
= 3.8 \text{ m/s}
$$

74. The given data can be used to calculate the force with which the road pushes against the car, which in turn is equal in magnitude to the force the car pushes against the road. The acceleration of the car on level ground is found from Eq. 2-11a.

$$
v - v_0 = at
$$
 \rightarrow $a = \frac{v - v_0}{t} = \frac{21 \text{ m/s} - 0}{14.0 \text{ s}} = 1.50 \text{ m/s}^2$

14.0 s *t* The force pushing the car in order to have this acceleration is found from Newton's $2nd$ law.

$$
F_{\rm p} = ma = (1100 \text{ kg})(1.50 \text{ m/s}^2) = 1650 \text{ N}
$$

We assume that this is the force pushing the car on the incline as well. Consider a free-body diagram for the car climbing the hill. We assume that the car will have a constant speed on the maximum incline. Write Newton's $2nd$ law for the *x* direction, with a net force of zero since the car is not accelerating.

$$
\sum F_x = F_p - mg \sin \theta = 0 \implies \sin \theta = \frac{F_p}{mg}
$$

$$
\theta = \sin^{-1} \frac{F_p}{mg} = \sin^{-1} \frac{1650 \text{ N}}{(1100 \text{ kg})(9.8 \text{ m/s}^2)} = 8.8^\circ
$$

75. Consider the free-body diagram for the watch. Write Newton's $2nd$ law for both the *x* and *y* directions. Note that the net force in the *y* direction is 0 because there is no acceleration in the *y* direction.

$$
\sum F_y = F_{\rm T} \cos \theta - mg = 0 \rightarrow F_{\rm T} = \frac{mg}{\cos \theta}
$$

$$
\sum F_x = F_{\rm T} \sin \theta = ma \rightarrow \frac{mg}{\cos \theta} \sin \theta = ma
$$

$$
a = g \tan \theta = (9.8 \text{ m/s}^2) \tan 25^\circ = 4.6 \text{ m/s}^2
$$

*m***g** $\overline{}$

 $\hat{\mathbf{F}}_{\rm N}$ $\overline{}$

 $\dot{\mathbf{F}}_{\rm fr}$ \rightarrow

 \rightarrow

Use Eq. 2-11a with $v_0 = 0$ to find the final velocity (takeoff speed).

$$
v - v_0 = at \rightarrow v = v_0 + at = 0 + (4.6 \text{ m/s}^2)(18 \text{ s}) = 82 \text{ m/s}
$$

76. (*a*) Consider the free-body diagrams for both objects, initially stationary. As sand is added, the tension will increase, and the force of static friction on the block will increase until it reaches its maximum of $F_f = \mu_sF_N$. Then the system will start to move. Write Newton's 2nd law for each object, when the static frictional force is at its maximum, but the objects are still stationary.

$$
\sum F_{y \text{ bucket}} = m_1 g - F_{\text{T}} = 0 \rightarrow F_{\text{T}} = m_1 g
$$

$$
\sum F_{y \text{ block}} = F_{\text{N}} - m_2 g = 0 \rightarrow F_{\text{N}} = m_2 g
$$

$$
\sum F_{x \text{ block}} = F_{\text{T}} - F_{\text{fr}} = 0 \rightarrow F_{\text{T}} = F_{\text{fr}}
$$

Equate the two expressions for tension, and substitute in the expression for the normal force to find the masses.

$$
m_1 g = F_{\text{fr}} \rightarrow m_1 g = \mu_s F_{\text{N}} = \mu_s m_2 g \rightarrow
$$

\n $m_1 = \mu_s m_2 = (0.450)(28.0 \text{ kg}) = 12.6 \text{ kg}$
\nThus 12.6 kg - 1.35 kg = 11.25 = 11.3 kg of sand was added.

(*b*) The same free-body diagrams can be used, but now the objects will accelerate. Since they are tied together, $a_{y1} = a_{x2} = a$. The frictional force is now kinetic friction, given by

 $F_{\text{fr}} = \mu_k F_{\text{N}} = \mu_k m_2 g$. Write Newton's 2nd laws for the objects in the direction of their acceleration.

$$
\sum F_{y \text{ bucket}} = m_1 g - F_T = m_1 a \rightarrow F_T = m_1 g - m_1 a
$$

$$
\sum F_{x \text{ block}} = F_T - F_{\text{fr}} = m_2 a \rightarrow F_T = F_{\text{fr}} + m_2 a
$$

Equate the two expressions for tension, and solve for the acceleration.

$$
m_1 g - m_1 a = \mu_k m_2 g + m_2 a
$$

\n
$$
a = g \frac{(m_1 - \mu_k m_2)}{(m_1 + m_2)} = (9.80 \text{ m/s}^2) \frac{(12.6 \text{kg} - (0.320)(28.0 \text{kg}))}{(12.6 \text{kg} + 28.0 \text{kg})} = \boxed{0.88 \text{ m/s}^2}
$$

77. Consider a free-body diagram for a grocery cart being pushed up an incline. Assuming that the cart is not accelerating, we write Newton's 2nd law for the *x* direction.

$$
\sum F_x = F_p - mg \sin \theta = 0 \rightarrow \sin \theta = \frac{F_p}{mg}
$$

$$
\theta = \sin^{-1} \frac{F_p}{mg} = \sin^{-1} \frac{20 \text{ N}}{(20 \text{ kg})(9.8 \text{ m/s}^2)} = 5.9^\circ
$$

^G 78. (*a*) To find the minimum force, assume that the piano is moving with a constant velocity. Since the piano is not accelerating, $F_{T4} = Mg$. For the lower pulley, since the tension in a rope is the same throughout, and since the pulley is not accelerating, it is seen that

$$
F_{T1} + F_{T2} = 2F_{T1} = Mg \rightarrow F_{T1} = F_{T2} = Mg/2.
$$

It also can be seen that since $F = F_{T2}$, that $|F = Mg/2|$.

(*b*) Draw a free-body diagram for the upper pulley. From that diagram, we see that

$$
F_{\text{t1}} = F_{\text{t1}} + F_{\text{t2}} + F = \frac{3Mg}{2}
$$

To summarize:

$$
F_{T1} = F_{T2} = Mg/2
$$
 $F_{T3} = 3 Mg/2$ $F_{T4} = Mg$

*M***g** G

 $\dot{\mathbf{F}}_{\texttt{T4}}$

showing only the net force. By Newton's $2nd$ law, the net force MUST point in the direction of the acceleration, and its magnitude is ma. That net force is the sum of ALL forces on the pilot. If we assume that the force of gravity and the force of the cockpit seat on the pilot are the only forces on the pilot, then in terms of vectors, $\vec{F}_{net} = m\vec{g} + \vec{F}_{set} = m\vec{a}$. Solve this equation for the force of the seat to find $\vec{F}_{\text{set}} = \vec{F}_{\text{net}} - m\vec{g} = m\vec{a} - m\vec{g}$. A vector diagram of that equation is as shown.

79. The acceleration of the pilot will be the same as that of the plane, since the pilot is at rest with respect to the plane. Consider first a free-body diagram of the pilot,

Solve for the force of the seat on the pilot using components.

$$
F_{x \text{ seat}} = F_{x \text{ net}} = ma \cos 45^{\circ} = (75 \text{ kg})(3.5 \text{ m/s}^2) \cos 45^{\circ} = 180 \text{ N}
$$

$$
F_{y \text{ seat}} = mg + F_{y \text{ net}} = mg + ma \sin 45^{\circ}
$$

$$
= (75 \text{ kg})(9.8 \text{ m/s}^2) + (75 \text{ kg})(3.5 \text{ m/s}^2)\cos 45^\circ = 920 \text{ N}
$$

The magnitude of the cockpit seat force is

$$
F = \sqrt{F_{x \text{ seat}}^2 + F_{y \text{ seat}}^2} = \sqrt{(180 \text{ N})^2 + (920 \text{ N})^2} = 940 \text{ N}
$$

The angle of the cockpit seat force is

$$
\theta = \tan^{-1} \frac{F_{y \text{ seat}}}{F_{x \text{ seat}}} = \tan^{-1} \frac{920 \text{ N}}{180 \text{ N}} = \boxed{79^{\circ}}
$$
 above the horizontal.

80. The initial speed is $v_i = (45 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) = 12.5 \text{ m/s}$. Use Eq. 2-11a to find the deceleration

of the child.

$$
v - v_0 = at
$$
 \rightarrow $a = \frac{v - v_0}{t} = \frac{0 - 12.5 \text{ m/s}}{0.20 \text{ s}} = -62.5 \text{ m/s}^2$.

The net force on the child is given by Newton's $2nd$ law.

$$
F_{\text{net}} = ma = (12 \text{ kg})(-62.5 \text{ m/s}^2) = \boxed{-7.5 \times 10^2 \text{ N}}
$$
, opposite to the velocity

We also assumed that friction between the seat and child is zero, and we assumed that the bottom of the seat is horizontal. If friction existed or if the seat was tilted back, then the force that the straps would have to apply would be less.

81 (*a*) The helicopter and frame will both have the same acceleration, and so can be treated as one object if no information about internal forces (like the cable tension) is needed. A free-body diagram for the helicopter-frame combination is shown. Write Newton's $2nd$ law for the combination, calling UP the positive direction.

$$
\sum F = F_{\text{lift}} - (m_{\text{H}} + m_{\text{F}}) g = (m_{\text{H}} + m_{\text{F}}) a \rightarrow
$$

\n
$$
F_{\text{lift}} = (m_{\text{H}} + m_{\text{F}}) (g + a) = (7650 \text{ kg} + 1250 \text{ kg}) (9.80 \text{ m/s}^2 + 0.80 \text{ m/s}^2)
$$

\n
$$
= 9.43 \times 10^4 \text{ N}
$$

(*b*) Now draw a free-body diagram for the frame alone, in order to find the tension in the cable. Again use Newton's 2nd law.

$$
\sum F = F_{\rm T} - m_{\rm F}g = m_{\rm F}a \rightarrow
$$

$$
F_{\rm T} = m_{\rm F}(g + a) = (1250 \text{ kg})(9.80 \text{ m/s}^2 + 0.80 \text{ m/s}^2) = 1.33 \times 10^4 \text{ N}
$$

- (*c*) The tension in the cable is the same at both ends, and so the cable exerts a force of $|1.33\times10^4$ N downward on the helicopter.
- 82. (*a*) We assume that the maximum horizontal force occurs when the train is moving very slowly, and so the air resistance is negligible. Thus the maximum acceleration is given by 5

$$
a_{\max} = \frac{F_{\max}}{m} = \frac{4.0 \times 10^5 \,\mathrm{N}}{6.6 \times 10^5 \,\mathrm{kg}} = \boxed{0.61 \,\mathrm{m/s}^2}.
$$

- (*b*) At top speed, we assume that the train is moving at constant velocity. Therefore the net force on the train is 0, and so the air resistance must be of the same magnitude as the horizontal pushing force, which is $\left| 1.5 \times 10^5 \text{ N} \right|$.
- 83. Consider the free-body diagram for the decelerating skater, moving to the right. It is apparent that $F_N = mg$ since there is no acceleration in the vertical direction. From Newton's 2nd law in the horizontal direction, we have \vec{r} \vec{v} \vec{v} $m\vec{g}$

$$
\sum F = F_{\rm fr} = ma \rightarrow -\mu_k mg = ma \rightarrow a = -\mu_k g
$$

Now use Eq. 2-11c to find the starting speed.

$$
v^{2} - v_{0}^{2} = 2a(x - x_{0}) \rightarrow
$$

\n
$$
v_{0} = \sqrt{v^{2} - 2a(x - x_{0})} = \sqrt{0 + 2\mu_{k}g(x - x_{0})} = \sqrt{2(0.10)(9.8 \text{ m/s}^{2})(75 \text{ m})} = 12 \text{ m/s}
$$

84. First calculate Karen's speed from falling. Let the downward direction be positive, and use Eq. 2-11c with $v_0 = 0$.

$$
v^{2} - v_{0}^{2} = 2a(y - y_{0}) \rightarrow v = \sqrt{0 + 2a(y - y_{0})} = \sqrt{2(9.8 \text{ m/s}^{2})(2.0 \text{ m})} = 6.26 \text{ m/s}
$$

Now calculate the average acceleration as the rope stops Karen, again using Eq. 2-11c, with down as positive.

$$
v^2 - v_0^2 = 2a(y - y_0)
$$
 $\rightarrow a = \frac{v^2 - v_0^2}{2(y - y_0)} = \frac{0 - (6.26 \text{ m/s})^2}{2(1.0 \text{ m})} = -19.6 \text{ m/s}^2$

© 2005 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

 $m_{\rm F}$ $\vec{\bf g}$ G

 \mathbf{F}_{N} \uparrow

 $\overline{}$

 \mathbf{F}_{fr} \overline{a}

 $\dot{\mathbf{F}}_{\text{lift}}$ $\overline{}$

$$
\begin{matrix}\n\vec{F}_{\text{rope}} \\
m\vec{g}\n\end{matrix}
$$

The negative sign indicates that the acceleration is upward. Since this is her acceleration, the net force on Karen is given by Newton's 2^{nd} law, $F_{net} = ma$. That net force will also be upward. Now consider the free-body diagram shown of Karen as she decelerates. Call DOWN the positive direction, and Newton's 2nd law says that $F_{\text{net}} = ma = mg - F_{\text{rope}} \rightarrow F_{\text{rope}} = mg - ma$. The ratio of this force to Karen's weight would be \sum_{rope} mg – ma₁₀ a₁₀ – 19.6 m/s² $1.0 - \frac{a}{2} = 1.0 - \frac{-19.6 \text{ m/s}}{0.8 \text{ m/s}^2}$ $9.8\,\mathrm{m/s}$ *a g* $\frac{F_{\text{rope}}}{mg} = \frac{mg - ma}{g} = 1.0 - \frac{a}{g} = 1.0 - \frac{-19.6 \text{ m/s}^2}{9.8 \text{ m/s}^2} = 3.0$. Thus the rope pulls upward on Karen with an average force of $\boxed{3.0 \text{ times her weight}}$.

A completely analogous calculation for Bill gives the same speed after the 2.0 m fall, but since he stops over a distance of 0.30 m, his acceleration is -65 m/s^2 , and the rope pulls upward on Bill with an average force of $\overline{7.7}$ times his weight. Thus \overline{Bill} is more likely to get hurt in the fall.

85. See the free-body diagram for the fish being pulled upward vertically. From Newton's $2nd$ law, calling the upward direction positive, we have

 $\sum F_v = F_T - mg = ma \rightarrow F_T = m(g + a)$

- (*a*) If the fish has a constant speed, then its acceleration is zero, and so $F_T = mg$. Thus the heaviest fish that could be pulled from the water in this case is $\left| 45 \text{ N } \right| (10 \text{ lb}) \right|$.
- (*b*) If the fish has an acceleration of 2.0 m/s², and F_T is at its maximum of 45 N, then solve the equation for the mass of the fish.

$$
m = \frac{F_{\rm T}}{g + a} = \frac{45 \text{ N}}{9.8 \text{ m/s}^2 + 2.0 \text{ m/s}^2} = 3.8 \text{ kg} \rightarrow
$$

$$
mg = (3.8 \text{ kg})(9.8 \text{ m/s}^2) = |37 \text{ N} (\approx 8.4 \text{ lb})|
$$

- (*c*) It is not possible to land a 15-lb fish using 10-lb line, if you have to lift the fish vertically. If the fish were reeled in while still in the water, and then a net used to remove the fish from the water, it might still be caught with the 10-lb line.
- 86. Choose downward to be positive. The elevator's acceleration is calculated by Eq. 2-11c.

$$
v^2 - v_0^2 = 2a(y - y_0)
$$
 $\rightarrow a = \frac{v^2 - v_0^2}{2(y - y_0)} = \frac{0 - (3.5 \text{ m/s})^2}{2(2.6 \text{ m})} = -2.356 \text{ m/s}^2$

See the free-body diagram of the elevator. Write Newton's $2nd$ law for the elevator.

$$
\sum F_y = mg - F_T = ma
$$

F_T = m(g - a) = (1300 kg)(9.80 m/s² - -2.356 m/s²) = 1.58×10⁴ N

87. (*a*) Draw a free-body diagram for each block, with no connecting tension. Because of the similarity of the free-body diagrams, we shall just analyze block 1. Write Newton's 2nd law in both the *x* and *y* directions. The net force in the *y* direction is zero, because there is no acceleration in the *y* direction.

$$
\sum F_{y1} = F_{N1} - m_1 g \cos \theta = 0 \rightarrow F_{N1} = m_1 g \cos \theta
$$

$$
\sum F_{x1} = m_1 g \sin \theta - F_{f1} = m_1 a_1 \rightarrow
$$

*m***g** \overline{a}

*m***g** $\frac{1}{2}$

 $\dot{\mathbf{F}}_{\text{T}}$ \rightarrow

 $\dot{\mathbf{F}}_{\text{T}}$ $\overline{}$

$$
a_1 = \frac{m_1 g \sin \theta - F_{\text{fr1}}}{m_1} = \frac{m_1 g \sin \theta - \mu_k m_1 g \cos \theta}{m_1} = g \left(\sin \theta - \mu_1 \cos \theta \right)
$$

$$
= \left(9.8 \text{ m/s}^2 \right) \left(\sin 30^\circ - 0.10 \cos 30^\circ \right) = \boxed{4.1 \text{ m/s}^2}
$$

The same analysis for block 2 would give

$$
a_2 = g(\sin\theta - \mu_2\cos\theta) = (9.8 \,\text{m/s}^2)(\sin 30^\circ - 0.20 \cos 30^\circ) = 3.2 \,\text{m/s}^2
$$

Since $a_2 < a_1$, if both blocks were released from rest, block # 1 would "gain" on block 2.

equations, consider that without the tension, $a_1 > a_2$. In (*b*) Now let the rope tension be present. Before writing the free-body diagram shown, m_1 now has even more force accelerating down the plane because of the addition of the tension force, which means $m₁$ has an even larger acceleration than before. And m_2 has less force accelerating it down the plane because of the addition of the tension force. Thus m_2 has a smaller acceleration than before. And so in any amount of time

 $\dot{\mathbf{F}}_{\texttt{N2}}$ $\overline{}$

*m***g** $\overrightarrow{\mathbf{F}_{N}}$ *m*g $\overline{}$

 m_1 **ğ**

θ

 \mathbf{F}_{fr2} G

 $\dot{\mathbf{F}}_{\text{T}}$ $\overline{}$

y

 $\dot{\mathbf{F}}_{\rm N1}$ $\overline{}$

 $\dot{\mathbf{F}}_{\text{\tiny T}}$ $\frac{1}{1}$

 \mathbf{F}_fr1 \rightarrow

considered, m_1 will move more distance down the plane upon release than block m_2 . The cord will go slack almost immediately after the blocks are released, and the blocks revert to the original free-body diagram. The conclusion is that the accelerations in this part of the problem are the same as they would be in part (*a*):

$$
a_1 = 4.1 \,\mathrm{m/s^2} \ ; \ a_2 = 3.2 \,\mathrm{m/s^2} \, .
$$

(*c*) Now reverse the position of the masses. Write Newton's $2nd$ law for each block, and assume that they have the same acceleration. The *y* equations and frictional forces are unchanged from the analysis in part (*a*), so we only write the *x* equations. After writing them, add them together (to eliminate the tension) and solve for the acceleration.

$$
\sum F_{x1} = m_1 g \sin \theta - F_{\text{fi}} - F_{\text{T}} = m_1 a
$$
\n
$$
\sum F_{x2} = m_2 g \sin \theta - F_{\text{fi}2} + F_{\text{T}} = m_2 a
$$
\n
$$
(m_1 + m_2) g \sin \theta - F_{\text{fi}1} - F_{\text{fi}2} = (m_1 + m_2) a
$$
\n
$$
a = \frac{(m_1 + m_2) g \sin \theta - \mu_1 m_1 g \cos \theta - \mu_2 m_2 g \cos \theta}{(m_1 + m_2)} = g \left[\sin \theta - \frac{\mu_1 m_1 + \mu_2 m_2}{m_1 + m_2} \cos \theta \right]
$$
\n
$$
= (9.8 \text{ m/s}^2) \left[\sin 30^\circ - \frac{(0.10)(1.0 \text{ kg}) + (0.20)(2.0 \text{ kg})}{3.0 \text{ kg}} \cos 30^\circ \right] = \frac{3.5 \text{ m/s}^2}{3.0 \text{ kg}}
$$

88. See the free-body diagram of the person in the elevator. The scale will read the normal force. Choose upward to be positive. From Newton's $2nd$ law,

$$
\sum F = F_{N} - mg = ma \rightarrow F_{N} = m(g + a)
$$

 (*a*, *b*, *c*) If the elevator is either at rest or moving with a constant vertical speed, either up or down, the acceleration is zero, and so

$$
F_{\rm N} = mg = (75.0 \text{ kg})(9.80 \text{ m/s}^2) = 7.35 \times 10^2 \text{ N} \quad m = \frac{F_{\rm N}}{g} = 75.0 \text{ kg}
$$

(*d*) When accelerating upward, the acceleration is $+3.0 \text{ m/s}^2$, and so

$$
F_{\rm N} = m\left(g+a\right) = (75.0 \text{ kg})\left(12.8 \text{ m/s}^2\right) = \boxed{9.60 \times 10^2 \text{ N}} \quad m = \frac{F_{\rm N}}{g} = \boxed{98.0 \text{ kg}}
$$

(*e*) When accelerating downward, the acceleration is -3.0 m/s^2 , and so

$$
F_{\rm N} = m(g+a) = (75.0 \text{ kg})(6.80 \text{ m/s}^2) = \boxed{5.10 \times 10^2 \text{ N}} \quad m = \frac{F_{\rm N}}{g} = \boxed{52.0 \text{ kg}}
$$

89. Since the climbers are on ice, the frictional force for the lower two climbers is negligible. Consider the freebody diagram as shown. Note that all the masses are the same. Write Newton's 2nd law in the *x* direction for the lowest climber, assuming he is at rest.

$$
\sum F_x = F_{T2} - mg \sin \theta = 0
$$

\n
$$
F_{T2} = mg \sin \theta = (75 \text{ kg})(9.8 \text{ m/s}^2) \sin 21.0^\circ
$$

\n
$$
= 2.6 \times 10^2 \text{ N}
$$

\n
$$
\theta = 2.6 \times 10^2 \text{ N}
$$

\n
$$
\theta = 2.6 \times 10^2 \text{ N}
$$

Write Newton's $2nd$ law in the *x* direction for the middle climber, assuming he is at rest.

$$
\sum F_x = F_{T1} - F_{T2} - mg \sin \theta = 0 \rightarrow F_{T1} = F_{T2} + mg \sin \theta = 2F_{T2} = \boxed{5.3 \times 10^2 \text{ N}}
$$

CHAPTER 5: Circular Motion; Gravitation

Answers to Questions

- The problem with the statement is that there is nothing to cause an outward force, and so the water removed from the clothes is not thrown outward. Rather, the spinning drum pushes INWARD on the clothes and water. But where there are holes in the drum, the drum can't push on the water, and so the water is not pushed in. Instead, the water moves tangentially to the rotation, out the holes, in a straight line, and so the water is separated from the clothes.
- 2. The centripetal acceleration for an object moving in circular motion is inversely proportional to the radius of the curve, given a constant speed $(a = v^2/r)$. So for a gentle curve (which means a large radius), the acceleration is smaller, while for a sharp curve (which means a small radius), the acceleration is larger.
- 3. The force that the car exerts on the road is the Newton's $3rd$ law reaction to the normal force of the road on the car, and so we can answer this question in terms of the normal force. The car exerts the greatest force on the road at the dip between two hills. There the normal force from the road has to both support the weight AND provide a centripetal upward force to make the car move in an upward curved path. The car exerts the least force on the road at the top of a hill. We have all felt the "floating upward" sensation as we have driven over the crest of a hill. In that case, there must be a net downward centripetal force to cause the circular motion, and so the normal force from the road does not completely support the weight.

- 4. There are at least three distinct major forces on the child. The force of gravity is acting downward on the child. There is a normal force from the seat of the horse acting upward on the child. There must be friction between the seat of the horse and the child as well, or the child could not be accelerated by the horse. It is that friction that provides the centripetal acceleration. There may be smaller forces as well, such as a reaction force on the child's hands if the child is holding on to part of the horse. Any force that has a radially inward component will contribute to the centripetal acceleration.
- 5. For the water to remain in the bucket, there must be a centripetal force forcing the water to move in a circle along with the bucket. That centripetal force gets larger with the tangential velocity of the water, since $F_p = mv^2/r$. The centripetal force at the top of the motion comes from a combination of the downward force of gravity and the downward normal force of the bucket on the water. If the bucket is moving faster than some minimum speed, the water will stay in the bucket. If the bucket is moving too slow, there is insufficient force to keep the water moving in the circular path, and it spills out.
- 6. The three major "accelerators" are the accelerator pedal, the brake pedal, and the steering wheel. The accelerator pedal (or gas pedal) can be used to increase speed (by depressing the pedal) or to decrease speed in combination with friction (by releasing the pedal). The brake pedal can be used to decrease speed by depressing it. The steering wheel is used to change direction, which also is an acceleration. There are some other controls which could also be considered accelerators. The parking brake can be used to decrease speed by depressing it. The gear shift lever can be used to decrease speed by downshifting. If the car has a manual transmission, then the clutch can be used to

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

decrease speed by depressing it (friction will slow the car). Finally, shutting the car off can be used to decrease its speed. Any change in speed or direction means that an object is accelerating.

7. When the child is on a level surface, the normal force between his chest and the sled is equal to the child's weight, and thus he has no vertical acceleration. When he goes over the hill, the normal force on him will be reduced. Since the child is moving on a curved path, there must be a net centripetal force towards the center of the path, and so the normal force does not completely support the weight. Write Newton's 2nd law for the radial direction, with inward as positive.

$$
\sum F_{R} = mg - F_{N} = mv^{2}/r \rightarrow F_{N} = mg - mv^{2}/r
$$

We see that the normal force is reduced from *mg* by the centripetal force.

- 8. When a bicycle rider leans inward, the bike tire pushes down on the ground at an angle. The road surface then pushes back on the tire both vertically (to provide the normal force which counteracts gravity) and horizontally toward the center of the curve (to provide the centripetal frictional force, enabling them to turn).
- 9. Airplanes bank when they turn because in order to turn, there must be a force that will be exerted towards the center of a circle. By tilting the wings, the lift force on the wings has a non-vertical component which points toward the center of the curve, providing the centripetal force. The banking Research angle can be computed from the free-body diagram. The sum of vertical forces must be zero for the plane to execute a level turn, and so $F_{\text{lift}} \cos \theta = mg$. The horizontal component of the lifting force must provide

the centripetal force to move the airplane in a circle.

$$
F_{\text{lift}} \sin \theta = m v^2 / r \rightarrow \frac{mg}{\cos \theta} \sin \theta = m v^2 / r \rightarrow \tan \theta = \frac{v^2}{Rg}
$$

- 10. She should let go of the string when the ball is at a position where the tangent line to the circle at the ball's location, when extended, \otimes passes through the target's position. That tangent line indicates the direction of the velocity at that instant, and if the centripetal force is removed, then the ball will follow that line horizontally. See the top-view diagram.
- 11. The apple does exert a gravitational force on the Earth. By Newton's $3rd$ law, the force on the Earth due to the apple is the same magnitude as the force on the apple due to the Earth – the weight of the apple. The force is also independent of the state of motion of the apple. So for both a hanging apple and a falling apple, the force on the Earth due to the apple is equal to the weight of the apple.
- 12. The gravitational force on the Moon is given by $G \frac{M_{\text{Earth}} M_{\text{Moon}}}{R^2}$, where *R* is the radius of the Moon's R^2 orbit. This is a radial force, and so can be expressed as $M_{M_{\text{OOD}}} v_{M_{\text{OOD}}}^2 / R$. This can be changed using the relationship $v_{\text{Moon}} = 2\pi R/T$, where *T* is the orbital period of the Moon, to $4\pi^2 M_{\text{Moon}} R/T^2$. If we equate these two expressions for the force, we get the following:

 $m\vec{g}$ $\left[\frac{1}{2}\right]$

 \mathbf{F}_{fr} \diagdown \diagdown

 \mathbf{F}_{N}

- $\frac{1}{2}$ Earth $M_{\text{Moon}} = 4\pi^2 M$ $p\left(\frac{T^2}{T^2}\right)$ $\frac{R^3}{T^3} = \frac{GM_{\text{Earth}}}{T^3}$ Thus the mass of the Farth determines the $\frac{M_{\text{Moon}}}{2} = 4\pi^2 M_{\text{Moon}} R/T^2 \rightarrow \frac{M_{\text{Earth}}}{T^2} = \frac{2M_{\text{Earth}}}{4\pi^2}$. Thus the mass of the Earth determines the $4\pi^2$ $G\frac{M_{\text{Earth}}M_{\text{Moon}}}{M_{\text{A}}M_{\text{$ R^2 *R* T^2 **4** π^2 . Thus the mass of the Earth determines the ratio R^3 / T^2 . If the mass of the Earth were doubled, then the ratio R^3 / T^2 would double, and so $R^3/T^2 = R^3/T^2$, where the primes indicated the "after doubling" conditions. For example, the radius might stay the same, and the period decrease by a factor of $\sqrt{2}$, which means the speed increased by a factor of $\sqrt{2}$. Or the period might stay the same, and the radius increase by a factor of $2^{1/3}$, which means the speed increased by the same factor of $2^{1/3}$. Or if both *R* and *T* were to double, keeping the speed constant, then R^3 / T^2 would double. There are an infinite number of other combinations that would also satisfy the doubling of R^3 / T^2 .
- 13. The gravitational pull is the same in each case, by Newton's $3rd$ law. The magnitude of that pull is given by $F = G \frac{M_{\text{Earth}} M_{\text{Moon}}}{r_{\text{Earth-Moon}}^2}$. To find the acceleration of each body, the gravitational pulling force is $r_{\text{Earth-Moon}}^2$. To find the acceleration of each body, the gravitational pulling force is divided by the mass of the body. Since the Moon has the smaller mass, it will have the larger acceleration.
- 14. The difference in force on the two sides of the Earth from the gravitational pull of either the Sun or the Moon is the primary cause of the tides. That difference in force comes about from the fact that the two sides of the Earth are a different distance away from the pulling body. Relative to the Sun, the difference in distance (Earth diameter) of the two sides from the Sun, relative to the average distance to the Sun, is given by $2R_{\text{Earth}}/R_{\text{Earth}} = 8.5 \times 10^{-5}$. The corresponding relationship between $2R_{\text{Earth}}/R_{\text{Earth}} = 8.5 \times 10^{-5}$. The corresponding relationship between the Earth and the Moon is $2R_{\text{Earth}}/R_{\text{Earth}} = 3.3 \times 10^{-2}$. Since the relative change in distance is much $2R_{\text{Earth}}$ $/R_{\text{Earth}}$ = 3.3 × 10⁻². Since the relative change in distance is much greater for the Earth-Moon combination, we see that the Moon is the primary cause of the Earth's
- 15. An object weighs more at the poles, due to two effects which complement (not oppose) each other. First of all, the Earth is slightly flattened at the poles and expanded at the equator, relative to a perfect sphere. Thus the mass at the poles is slightly closer to the center, and so experiences a slightly larger gravitational force. Secondly, objects at the equator have a centripetal acceleration due to the rotation of the Earth that objects at the poles do not have. To provide that centripetal acceleration, the apparent weight (the radially outward normal force of the Earth on an object) is slightly less than the gravitational pull inward. So the two effects both make the weight of an object at the equator less than that at the poles.

tides.

- 16. The Moon is not pulled away from the Earth because both the Moon and the Earth are experiencing the same radial acceleration due to the Sun. They both have the same period around the Sun because they are both, on average, the same distance from the Sun, and so they travel around the Sun together.
- 17. The centripetal acceleration of Mars is smaller than that of Earth. The acceleration of each planet can be found by dividing the gravitational force on each planet by the planet's mass. The resulting acceleration is inversely proportional to the square of the distance of the planet from the Sun. Since Mars is further from the Sun than the Earth is, the acceleration of Mars will be smaller. Also see the equation below.

$$
F_{\text{on planet}} = G \frac{M_{\text{sun}} M_{\text{planet}}}{r_{\text{Sun to planet}}^2} \qquad a_{\text{planet}} = \frac{F_{\text{on planet}}}{M_{\text{planet}}} = G \frac{M_{\text{sun}}}{r_{\text{Sun to planet}}^2}
$$

- 18. In order to orbit, a satellite must reach an orbital speed relative to the center of the Earth. Since the satellite is already moving eastward when launched (due to the rotation speed at the surface of the Earth), it requires less additional speed to launch it east to obtain the final orbital speed.
- 19. The apparent weight (the normal force) would be largest when the elevator is accelerating upward. From the free-body diagram, with up as positive, we have $F_{\text{N}} - mg = ma \rightarrow F_{\text{N}} = m(g + a)$. With a positive acceleration, the normal force is greater than your weight. The apparent weight would be the least when in free fall, because there the apparent weight is zero, since $a = -g$. When the elevator is moving with constant speed, your apparent weight would be the same as it is on the ground, since $a = 0$ and so $F_{\rm N}$ = mg. *mg* .
- 20. A satellite remains in orbit due to the combination of gravitational force on the satellite directed towards the center of the orbit and the tangential speed of the satellite. First, the proper tangential speed had to be established by some other force than the gravitational force. Then, if the satellite has the proper combination of speed and radius such that the force required for circular motion is equal to the force of gravity on the satellite, then the satellite will maintain circular motion.
- 21. The passengers, as seen in the diagram, are standing on the floor.
	- (*a*) If a passenger held an object beside their waist and then released it, the object would move in a straight line, tangential to the circle in which the passenger's waist was moving when the object was released. In the figure, we see that the released object \bigvee dropped would hit the rotating shell, and so fall to the floor, but behind the person. The passenger might try to explain such motion by
	- inventing some kind of "retarding" force on dropped objects, when really there is no such force. (*b*) The floor exerts a centripetal force on the feet, pushing them towards the center. This force has the same direction ("upwards", away from the floor) that a passenger would experience on Earth, and so it seems to the passenger that gravity must be pulling them "down". Actually, the passengers are pushing down on the floor, because the floor is pushing up on them.
	- (*c*) The "normal" way of playing catch, for example, would have to change. Since the artificial gravity is not uniform, passengers would have to re-learn how to throw something across the room to each other. There would not be projectile motion as we experience it on Earth. Also, if the cylinder were small, there might be a noticeable difference in the acceleration of our head vs. our feet. Since the head is closer to the center of the circle than the feet, and both the head and the feet have the same period of rotation, the centripetal acceleration $(a_R = 4\pi^2 r/T^2)$ is $a_{\rm R} = 4\pi^2 r/T^2$ is

smaller for the head. This might cause dizziness or a light-headed feeling.

- 22. When the runner has both feet off the ground, the only force on the runner is gravity there is no normal force from the ground on the runner. This lack of normal force is interpreted as "free fall" and "apparent weightlessness".
- 23. By Kepler's 2^{nd} law, the Earth moves faster around the Sun when it is nearest the Sun. Kepler's 2^{nd} nd law says that an imaginary line drawn from the Sun to the Earth sweeps out equal areas in equal

times. So when the Earth is close to the Sun, it must move faster to sweep out a given area than when the Earth is far from the Sun. Thus the Earth is closer to the Sun in January.

24. Let the mass of Pluto be *M*, the mass of the moon be *m*, the radius of the moon's orbit be *R*, and the

period of the moon's orbit be *T*. Then Newton's second law for the moon orbiting Pluto will be $F = \frac{GmM}{R^2}$. If that moon's orbit is a circle, then the form of the force must be centripetal, and so R^2 $F = \frac{3m\pi}{R^2}$. If that moon's orbit is a circle, then the form of the force must be centripetal, and so $F = mv^2/R$. Equate these two expressions for the force on the moon, and substitute the relationship

for a circular orbit that $v = 2\pi R/T$.

$$
\frac{GmM}{R^2} = \frac{mv^2}{R} = \frac{4\pi^2 mR}{T^2} \quad \to \quad M = \frac{4\pi^2 R^3}{GT^2} \, .
$$

. Thus a value for the mass of Pluto can be calculated knowing the period and radius of the moon's orbit.

Solutions to Problems

- 1. (*a*) Find the centripetal acceleration from Eq. 5-1. $a_{\rm g} = v^2/r = (1.25 \,\rm m/s)^2 / 1.10 \,\rm m = 1.42 \,\rm m/s^2$ $R = r l^{2}$ (1.25 m/s) [1.16 m = [1.12 m/s]
	- (b) The net horizontal force is causing the centripetal motion, and so will be the centripetal force. $R = \frac{m a}{R} - (25.0 \text{ kg})(1.12 \text{ m})^3 - (25.5 \text{ m})^3$ $F_{\rm g} = ma_{\rm g} = (25.0 \text{ kg})(1.42 \text{ m/s}^2) = 35.5 \text{ N}$
- 2. Find the centripetal acceleration from Eq. 5-1.

$$
a_{R} = v^{2} / r = \frac{(525 \text{ m/s})^{2}}{6.00 \times 10^{3} \text{ m}} = (45.94 \text{ m/s}^{2}) \left(\frac{1 g}{9.80 \text{ m/s}^{2}}\right) = \boxed{4.69 g's}
$$

3. The centripetal acceleration is
$$
a_R = v^2/R_{\text{Earth}} = \frac{\left(2\pi R_{\text{Earth}}/T\right)^2}{R_{\text{Earth}}}
$$
. The force (from

Newton's $2nd$ law) is $F_R = m_{\text{Earth}} a_R$. The period is one year, converted into seconds.

$$
a_{R} = \frac{4\pi^{2} R_{\text{Earth}}}{T^{2}} = \frac{4\pi^{2} (1.50 \times 10^{11} \text{ m})}{(3.15 \times 10^{7} \text{ sec})^{2}} = 5.97 \times 10^{-3} \text{ m/s}^{2}
$$

$$
F_{R} = ma = (5.97 \times 10^{24} \text{ kg})(5.97 \times 10^{-3} \text{ m/s}^{2}) = 3.56 \times 10^{22} \text{ N}
$$

The Sun exerts this force on the Earth. It is a gravitational force.

4. The speed can be found from the centripetal force and centripetal acceleration.

$$
F_{\rm R} = ma_{\rm R} = mv^2/r
$$
 $\rightarrow v = \sqrt{\frac{F_{\rm R}r}{m}} = \sqrt{\frac{(210 \text{ N})(0.90 \text{ m})}{2.0 \text{ kg}}} = 9.7 \text{ m/s}$

5. The orbit radius will be the sum of the Earth's radius plus the 400 km orbit height. The orbital period is about 90 minutes. Find the centripetal acceleration from these data.

$$
r = 6380 \text{ km} + 400 \text{ km} = 6780 \text{ km} = 6.78 \times 10^6 \text{ m} \qquad T = 90 \text{ min} \left(\frac{60 \text{ sec}}{1 \text{ min}} \right) = 5400 \text{ sec}
$$

$$
a_R = \frac{4\pi^2 r}{T^2} = \frac{4\pi^2 \left(6.78 \times 10^6 \text{ m} \right)}{\left(5400 \text{ sec} \right)^2} = \left(9.18 \text{ m/s}^2 \right) \left(\frac{1 g}{9.80 \text{ m/s}^2} \right) = 0.937 \approx \boxed{0.9 g\text{'s}}
$$

Notice how close this is to *g*, because the shuttle is not very far above the surface of the Earth, relative to the radius of the Earth.

6. To find the period, the rotational speed (in rev/min) is reciprocated to have min/rev, and then converted to sec/rev. Use the period to find the speed, and then the centripetal acceleration.

$$
T = \left(\frac{1 \text{ min}}{45 \text{ rev}}\right) \left(\frac{60 \text{ sec}}{1 \text{ min}}\right) = 1.333 \frac{\text{sec}}{\text{rev}} \qquad r = 0.16 \text{ m} \qquad v = \frac{2\pi r}{T} = \frac{2\pi (0.16 \text{ m})}{1.333 \text{ sec}} = 0.754 \text{ m/s}
$$

$$
a_{\text{R}} = v^2 / r = \frac{(0.754 \text{ m/s})^2}{0.16 \text{ m}} = \boxed{3.6 \text{ m/s}^2}
$$

- 7. See the free-body diagram in the textbook. Since the object is moving in a circle with a constant speed, the net force on the object at any point must point to the center of the circle.
	- (α) Take positive to be downward. Write Newton's 2nd law in the downward direction.

$$
\sum F_{R} = mg + F_{T1} = ma_{R} = mv^{2}/r \rightarrow
$$

$$
F_{T1} = m(v^{2}/r - g) = (0.300 \text{ kg}) \left(\frac{(4.00 \text{ m/s})^{2}}{0.720 \text{ m}} - 9.80 \text{ m/s}^{2} \right) = 3.73 \text{ N}
$$

This is a downward force, as expected.

(*b*) Take positive to be upward. Write Newton's $2nd$ law in the upward direction. T_1^2 $m_6 - m_1 - m_1$ T_1 T_2 $F_R = F_{T2} - mg = ma = mv^2/r \rightarrow$

$$
\sum F_R = F_{T2} - mg = ma = mv^2 / r \rightarrow
$$

\n
$$
F_{T1} = m(v^2 / r + g) = (0.300 \text{ kg}) \left(\frac{(4.00 \text{ m/s})^2}{0.720 \text{ m}} + 9.80 \text{ m/s}^2 \right) = 9.61 \text{ N}
$$

This is an upward force, as expected.

8. The centripetal force that the tension provides is given by $F_R = mv^2/r$. Solve that for the speed.

$$
v = \sqrt{\frac{F_{\rm g}r}{\rm m}} = \sqrt{\frac{(75 \text{ N})(1.3 \text{ m})}{0.45 \text{ kg}}} = \boxed{15 \text{ m/s}}
$$

9. A free-body diagram for the car at one instant of time is shown. In the diagram, the car is coming out of the paper at the reader, and the center of the circular path is to the right of the car, in the plane of the paper. If the car has its maximum speed, it would be on the verge of slipping, and the force of static friction would be at its maximum value. The vertical forces (gravity and normal force) are of the same magnitude, because the car is not accelerating vertically. We assume that the force

of friction is the force causing the circular motion.
\n
$$
F_{\rm R} = F_{\rm fr} \rightarrow m v^2 / r = \mu_s F_{\rm N} = \mu_s mg \rightarrow v = \sqrt{\mu_s rg} = \sqrt{(0.80)(77 \text{ m})(9.8 \text{ m/s}^2)} = 25 \text{ m/s}
$$

Notice that the result is independent of the car's mass.

10. In the free-body diagram, the car is coming out of the paper at the reader, and the center of the circular path is to the right of the car, in the plane of the paper. The vertical forces (gravity and normal force) are of the same magnitude, because the car is not accelerating vertically. We assume that the force of friction is the force causing the circular motion. If the car has its maximum speed, it would be on the verge of slipping, and the force of static friction would be at its maximum value.

$$
F_{R} = F_{\text{fr}} \rightarrow mv^{2}/r = \mu_{s}F_{N} = \mu_{s}mg \rightarrow \mu_{s} = \frac{v^{2}}{rg} = \frac{\left[(95 \text{ km/hr}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/hr}} \right) \right]^{2}}{(85 \text{ m})(9.8 \text{ m/s}^{2})} = \boxed{0.84}
$$

Notice that the result is independent of the car's mass.

11. Since the motion is all in a horizontal circle, gravity has no influence on the analysis. Set the general expression for centripetal force equal to the stated force in the problem.

$$
F_{\rm R} = m v^2 / r = 7.85 W = 7.85 mg \rightarrow v = \sqrt{7.85 r g} = \sqrt{7.85 (12.0 \text{ m}) (9.8 \text{ m/s}^2)} = 30.4 \text{ m/s}
$$

$$
(30.4 \text{ m/s}) \left(\frac{1 \text{ rev}}{2\pi (12.0 \text{ m})}\right) = 0.403 \text{ rev/s}
$$

12. The force of static friction is causing the circular motion – it is the centripetal force. The coin slides off when the static frictional force is not large enough to move the coin in a circle. The maximum static frictional force is the coefficient of static friction times the normal force, and the normal force is equal to the $m\vec{g}$ weight of the coin as seen in the free-body diagram, since there is no vertical acceleration. In the free-body diagram, the coin is coming out of the paper and the center of the circle is to the right of the coin, in the plane of the paper.

The rotational speed must be changed into a linear speed.

$$
v = \left(36 \frac{\text{rev}}{\text{min}}\right) \left(\frac{1 \text{ min}}{60 \text{ s}}\right) \left(\frac{2\pi (0.11 \text{ m})}{1 \text{ rev}}\right) = 0.4147 \text{ m/s}
$$

$$
F_{\text{R}} = F_{\text{fr}} \rightarrow m v^2 / r = \mu_s F_{\text{N}} = \mu_s mg \rightarrow \mu_s = \frac{v^2}{rg} = \frac{(0.4147 \text{ m/s})^2}{(0.11 \text{ m})(9.8 \text{ m/s}^2)} = 0.16
$$

13. At the top of a circle, a free-body diagram for the passengers would be as shown, assuming the passengers are upside down. Then the car's normal force would be pushing DOWN on the passengers, as shown in the diagram. We assume no safety devices are present. Choose the positive direction to be down, and write Newton's $2nd$ law for the passengers.

$$
\sum F = F_{N} + mg = ma = mv^{2}/r \rightarrow F_{N} = m(v^{2}/r - g)
$$

We see from this expression that for a high speed, the normal force is positive, meaning the passengers are in contact with the car. But as the speed decreases, the normal force also decreases. If the normal force becomes 0, the passengers are no longer in contact with the car – they are in free fall. The limiting condition is

$$
v_{\min}^2 / r - g = 0 \rightarrow v_{\min} = \sqrt{rg} = \sqrt{(9.8 \text{ m/s}^2)(7.4 \text{ m})} = 8.5 \text{ m/s}
$$

14. (*a*) A free-body diagram of the car at the instant it is on the top of the hill is shown. Since the car is moving in a circular path, there must be a net centripetal force downward. Write Newton's 2nd law for the car, with down as the positive direction.
 $\sum F = ma \ E = ma = mv^2/r$

$$
\sum F_{R} = mg - F_{N} = ma = mv^{2}/r \rightarrow
$$

$$
F_{N} = m(g - v^{2}/r) = (950 \text{ kg}) \left(9.8 \text{ m/s}^{2} - \frac{(22 \text{ m/s})^{2}}{95 \text{ m}} \right) = \boxed{4.5 \times 10^{3} \text{ N}}
$$

(*b*) The free-body diagram for the passengers would be the same as the one for the car, leading to the same equation for the normal force on the passengers.

$$
F_{\rm N} = m\left(g - v^2/r\right) = (72 \text{ kg})\left(9.8 \text{ m/s}^2 - \frac{\left(22 \text{ m/s}\right)^2}{95 \text{ m}}\right) = \boxed{3.4 \times 10^2 \text{ N}}
$$

Notice that this is significantly less than the 700-N weight of the passenger. Thus the passenger will feel "light" as they drive over the hill.

(c) For the normal force to be zero, we see that we must have
\n
$$
F_N = m(g - v^2/r) = 0 \rightarrow g = v^2/r \rightarrow v = \sqrt{gr} = \sqrt{(9.8 \text{ m/s}^2)(95 \text{ m})} = \boxed{31 \text{ m/s}}.
$$

15. The free-body diagram for passengers at the top of a Ferris wheel is as shown. F_N is the normal force of the seat pushing up on the passenger. The sum of the forces on the passenger is producing the centripetal motion, and so must be a centripetal force. Call the downward direction positive. Newton's 2^{nd} law for \vec{F}_{N} the passenger is:

 $F_{\rm T}$ \bigcap $m\vec{g}$

$$
\sum F_{\rm R} = mg - F_{\rm N} = ma = mv^2/r
$$

Since the passenger is to feel "weightless", they must lose contact with their seat, and so the normal force will be 0.
 $\cos \theta = \sqrt{2\pi} \left[\frac{\sqrt{2(8\pi\sqrt{c^2})(75\pi)}}{2(8.2 \times 10^{-11} \text{ s})} \right]$

$$
mg = mv^{2}/r \rightarrow v = \sqrt{gr} = \sqrt{(9.8 \text{ m/s}^{2})(7.5 \text{ m})} = 8.6 \text{ m/s}
$$

$$
\left(8.6 \frac{\text{m}}{\text{s}}\right) \left(\frac{1 \text{ rev}}{2\pi (7.5 \text{ m})}\right) \left(\frac{60 \text{ s}}{1 \text{ min}}\right) = \boxed{11 \text{ rpm}}
$$

16. (*a*) At the bottom of the motion, a free-body diagram of the bucket would be as shown. Since the bucket is moving in a circle, there must be a net force on it towards the center of the circle, and a centripetal acceleration. Write Newton's $2nd$ law for the bucket, with up as the positive direction.

$$
\sum F_R = F_T - mg = ma = mv^2/r \rightarrow \text{Area}(\sqrt{1.10 \text{ m}}) = \sqrt{\frac{r(F_T - mg)}{m}} = \sqrt{\frac{(1.10 \text{ m})[25.0 \text{ N} - (2.00 \text{ kg})(9.80 \text{ m/s}^2)]}{2.00 \text{ kg}}} = 1.723 \approx 1.7 \text{ m/s}
$$

(*b*) A free-body diagram of the bucket at the top of the motion is shown. Since the bucket is moving in a circle, there must be a net force on it towards the center of the circle, and a centripetal acceleration. Write Newton's $2nd$ law for the bucket, with down as the positive direction.

$$
\sum F_{R} = F_{T} + mg = ma = mv^{2}/r \rightarrow v = \sqrt{\frac{r(F_{T} + mg)}{m}}.
$$

If the tension is to be zero, then

$$
v = \sqrt{\frac{r(0+mg)}{m}} = \sqrt{rg} = \sqrt{(1.1 \text{ m})(9.8 \text{ m/s}^2)} = 3.3 \text{ m/s}
$$

The bucket must move faster than 3.3 m/s in order for the rope not to go slack.

17. The centripetal acceleration of a rotating object is given by
$$
a_R = v^2/r
$$
. Thus
\n
$$
v = \sqrt{a_R r} = \sqrt{(1.15 \times 10^5 g) r} = \sqrt{(1.15 \times 10^5)(9.80 m/s^2)(9.00 \times 10^{-2} m)} = 3.18 \times 10^2 m/s.
$$
\n
$$
(3.18 \times 10^2 m/s) \left(\frac{1 \text{ rev}}{2\pi (9.00 \times 10^{-2} m)}\right) \left(\frac{60 s}{1 min}\right) = 3.38 \times 10^4 \text{ rpm}.
$$

18. Consider the free-body diagram for a person in the "Rotor-ride". \vec{F}_{N} is the normal force of contact between the rider and the wall, and \vec{F}_{f} is the static frictional force between the back of the rider and the wall. Write Newton's 2^{nd} law for the vertical forces, noting that there is no vertical acceleration.
 $\sum F_y = F_{\text{fr}} - mg = 0 \rightarrow F_{\text{fr}} = mg$

$$
\sum F_{y} = F_{\text{fr}} - mg = 0 \rightarrow F_{\text{fr}} = mg
$$

If we assume that the static friction force is a maximum, then \sqrt{mg}

$$
F_{\rm fr} = \mu_s F_{\rm N} = mg \rightarrow F_{\rm N} = mg/\mu_s \,.
$$

But the normal force must be the force causing the centripetal motion – it is the only force pointing to the center of rotation. Thus $F_R = F_N = m v^2 / r$. Using $v = 2\pi r / T$, we have

 $2²$. Equate the two expressions for the normal force and solve for the coefficient of $F_{N} = \frac{4\pi^{2}mr}{T^{2}}$. Equate the two expressions for the normal force and solve for the coefficient of T^2 and T^2 and . Equate the two expressions for the normal force and solve for the coefficient of

friction. Note that since there are 0.5 rev per sec, the period is 2.0 sec.

$$
F_N = \frac{4\pi^2 mr}{T^2} = \frac{mg}{\mu_s} \quad \rightarrow \quad \mu_s = \frac{gT^2}{4\pi^2 r} = \frac{(9.8 \,\mathrm{m/s^2})(2 \,\mathrm{s})^2}{4\pi^2 (4.6 \,\mathrm{m})} = 0.22.
$$

Any larger value of the coefficient of friction would mean that the normal force could be smaller to achieve the same frictional force, and so the period could be longer or the cylinder smaller.

There is no force pushing outward on the riders. Rather, the wall pushes against the riders, so by Newton's $3rd$ law the riders push against the wall. This gives the sensation of being pressed into the wall.

19. Since mass *m* is dangling, the tension in the cord must be equal to the weight of mass *m*, and so $F_T = mg$. That same tension is in the other end of the cord, maintaining the circular motion of mass

M, and so $F_T = F_R = Ma_R = M v^2 / r$. Equate the two expressions for the tension and solve for the velocity.

$$
M v^2 / r = mg \rightarrow v = \sqrt{mgR/M}.
$$

20. A free-body diagram for the ball is shown. The tension in the suspending cord must not only hold the ball up, but also provide the centripetal force needed to make the ball move in a circle. Write Newton's $2nd$ law for the vertical direction, noting that the ball is not If we assume that the static friction force is a maximum, then
 $P_n = \mu_i P_n = mg \rightarrow F_n = mg [H_i,$

But the normal force must be the force causing the centripetal motion – it is the

only force pointing to the center of rotation. Thu

$$
\sum F_y = F_{\rm T} \sin \theta - mg = 0 \rightarrow F_{\rm T} = \frac{mg}{\sin \theta}
$$

The force moving the ball in a circle is the horizontal portion of the tension. Write Newton's $2nd$ law for that radial motion.

$$
\sum F_{\rm R} = F_{\rm T} \cos \theta = ma_{\rm R} = mv^2 / r
$$

Substitute the expression for the tension from the first equation into the second equation, and solve for the angle. Also substitute in the fact that for a rotating object, $v = 2\pi r/T$. Finally we recognize that if the string is of length L, then the radius of the circle is $r = L \cos \theta$.

$$
F_{\rm T} \cos \theta = \frac{mg}{\sin \theta} \cos \theta = \frac{mv^2}{r} = \frac{4\pi^2 mr}{T^2} = \frac{4\pi^2 mL \cos \theta}{T^2} \rightarrow
$$

\n
$$
\sin \theta = \frac{gT^2}{4\pi^2 L} \rightarrow \theta = \sin^{-1} \frac{gT^2}{4\pi^2 L} = \sin^{-1} \frac{(9.80 \text{ m/s}^2)(0.500 \text{ s})^2}{4\pi^2 (0.600 \text{ m})} = 5.94^{\circ}
$$

\nThe tension is then given by $F_{\rm T} = \frac{mg}{\sin \theta} = \frac{(0.150 \text{ kg})(9.80 \text{ m/s}^2)}{\sin 5.94^{\circ}} = 14.2 \text{ N}$

21. Since the curve is designed for 75 km/h, traveling at a higher speed with the same radius means that more centripetal force will be required. That extra centripetal force will be supplied by a force of static friction, downward along the incline. See the free-body diagram for the car on the incline. Note that from Example 5-7 in the textbook, the no-friction banking angle is given by $m\vec{g}$ \vec{F}_{fr}

travelling at a higher speed with
etal force will be required. That
by a force of static friction,
re-body diagram for the car on
l.0 m/s

$$
\overrightarrow{F}_{\text{N}}
$$

\n1.0 m/s

$$
\theta = \tan^{-1} \frac{v^2}{rg} = \tan^{-1} \frac{\left[(75 \text{ km/h}) \left(\frac{1.0 \text{ m/s}}{3.6 \text{ km/h}} \right) \right]^2}{(88 \text{ m}) \left(9.8 \text{ m/s}^2 \right)} = 26.7^\circ
$$

Write Newton's 2^{nd} law in both the *x* and *y* directions. The car will have no acceleration in the *y* direction, and centripetal acceleration in the *x* direction. We also assume that the car is on the verge of skidding, so that the static frictional force has its maximum value of $F_{\text{fr}} = \mu_s F_{\text{N}}$. Solve each equation for the normal force.

$$
\sum F_y = F_{N} \cos \theta - mg - F_{fr} \sin \theta = 0 \rightarrow F_{N} \cos \theta - \mu_s F_{N} \sin \theta = mg \rightarrow
$$

\n
$$
F_{N} = \frac{mg}{(\cos \theta - \mu_s \sin \theta)}
$$

\n
$$
\sum F_x = F_{N} \sin \theta + F_{fr} \cos \theta = F_{R} = mv^2 / r \rightarrow F_{N} \sin \theta + \mu_s F_{N} \cos \theta = mv^2 / r \rightarrow
$$

\n
$$
F_{N} = \frac{mv^2 / r}{(\sin \theta + \mu_s \cos \theta)}
$$

Equate the two expressions for F_N , and solve for the coefficient of friction. The speed of rounding

the curve is given by $v = (95 \text{ km/h}) \left| \frac{1.6 \text{ m/s}}{2.6 \times 10^{-15}} \right| = 26.39 \text{ m/s}.$ $1.0 \,\mathrm{m/s}$ $26.20 \,\mathrm{J}$ (95 km/h) $\frac{2.6 \text{ km/s}}{100}$ = 26.39 m/s. 3.6 km/h $\frac{1}{2}$ 2 $\left($ $\frac{mg}{(\cos \theta - \mu_s \sin \theta)} = \frac{mv^2/r}{(\sin \theta + \mu_s \cos \theta)} \rightarrow$

$$
\mu_s = \frac{\left(\frac{v^2}{r}\cos\theta - g\sin\theta\right)}{\left(g\cos\theta + \frac{v^2}{r}\sin\theta\right)} = \frac{\left(\frac{v^2}{r} - g\tan\theta\right)}{\left(g + \frac{v^2}{r}\tan\theta\right)} = \frac{\left(\frac{(26.39 \text{ m/s})^2}{88 \text{ m}} - (9.8 \text{ m/s}^2)\tan 26.7^\circ\right)}{\left(9.8 \text{ m/s}^2 + \frac{(26.39 \text{ m/s})^2}{88 \text{ m}}\tan 26.7^\circ\right)} = \boxed{0.22}
$$

22. The car moves in a horizontal circle, and so there must be a net horizontal centripetal force. The car is not accelerating vertically. Write Newton's 2nd law for both the *x* and *y* directions.

$$
\sum F_y = F_N \cos \theta - mg = 0 \rightarrow F_N = \frac{mg}{\cos \theta}
$$

$$
\sum F_x = \sum F_R = F_N \sin \theta = ma_x
$$

The amount of centripetal force needed for the car to round the curve is

$$
F_{\rm R} = m v^2 / r = (1200 \text{ kg}) \frac{\left[(95 \text{ km/h}) \left(\frac{1.0 \text{ m/s}}{3.6 \text{ km/h}} \right) \right]^2}{67 \text{ m}} = 1.247 \times 10^4 \text{ N}.
$$

The actual horizontal force available from the normal force is
\n
$$
F_{\text{N}} \sin \theta = \frac{mg}{\cos \theta} \sin \theta = mg \tan \theta = (1200 \text{ kg})(9.80 \text{ m/s}^2) \tan 12^\circ = 2.500 \times 10^3 \text{ N}.
$$

Thus more force is necessary for the car to round the curve than can be supplied by the normal force. That extra force will have to have a horizontal component to the right in order to provide the extra centripetal $\begin{vmatrix} x \end{vmatrix}$ force. Accordingly, we add a frictional force pointed down the plane. That corresponds to the car not being able to make the curve without friction.

Again write Newton's $2nd$ law for both directions, and again the *y* acceleration is zero.

$$
\sum F_y = F_N \cos \theta - mg - F_{fr} \sin \theta = 0 \implies F_N = \frac{mg + F_{fr} \sin \theta}{\cos \theta}
$$

$$
\sum F_x = F_N \sin \theta + F_{fr} \cos \theta = mv^2 / r
$$

Substitute the expression for the normal force from the *y* equation into the *x* equation, and solve for the friction force.

$$
\frac{mg + F_{\text{fr}} \sin \theta}{\cos \theta} \sin \theta + F_{\text{fr}} \cos \theta = mv^2 / r \rightarrow (mg + F_{\text{fr}} \sin \theta) \sin \theta + F_{\text{fr}} \cos^2 \theta = m \frac{v^2}{r} \cos \theta
$$

$$
F_{\text{fr}} = m \frac{v^2}{r} \cos \theta - mg \sin \theta = (1.247 \times 10^4 \text{ N}) \cos 12^\circ - (1200 \text{ kg}) (9.80 \text{ m/s}^2) \sin 12^\circ
$$

$$
= 9.752 \times 10^3 \text{ N}
$$

So a frictional force of 9.8×10^3 N down the plane is needed to provide the necessary centripetal force to round the curve at the specified speed.

23. If the masses are in line and both have the same frequency, then they will always stay in line. Consider a free-body diagram for both masses, from a side view, at the instant that they are to the left of the post. Note that the same tension that pulls inward on mass 2 pulls outward on mass 1, by Newton's $\mathbf{3}^{\text{rd}}$ law. Also notice that since there is no vertical $m_2 \vec{g}$ $m_3 \vec{g}$ $m_1 \vec{g}$

acceleration, the normal force on each mass is equal to its

weight. Write Newton's 2nd law for the horizontal direction for both masses, noting that they are in uniform circular motion.

$$
\sum F_{1R} = F_{T1} - F_{T2} = m_1 a_1 = m_1 v_1^2 / r_1 \qquad \sum F_{2R} = F_{T2} = m_2 a_2 = m_2 v_2^2 / r_2
$$

The speeds can be expressed in terms of the frequency as follows: $v = \frac{f^2 - f}{f^2 - f} = 2\pi r f$. rev $(2\pi r)$ 2 $2\pi r f$. sec $/(1 \text{ rev})$ r) \sim ϵ

$$
F_{T2} = m_2 v_2^2 / r_2 = m_2 (2\pi r_2 f)^2 / r_2 = 4\pi^2 m_2 r_2 f^2
$$

$$
F_{T1} = F_{T2} + m_1 v_1^2 / r_1 = 4\pi m_2 r_2 f^2 + m_1 (2\pi r_1 f)^2 / r_1 = 4\pi^2 f^2 (m_1 r_1 + m_2 r_2)
$$

24. The fact that the pilot can withstand 9.0 *g*'s without blacking out, along with the speed of the aircraft, will determine the radius of the circle that he must fly as he pulls out of the dive. To just avoid crashing into the sea, he must begin to form that circle (pull out of the dive) at a height equal to the radius of that circle.

$$
a_R = v^2/r = 9.0g \rightarrow r = \frac{v^2}{9.0g} = \frac{(310 \text{ m/s})^2}{9.0(9.80 \text{ m/s}^2)} = 1.1 \times 10^3 \text{ m}
$$

25. From example 5.8, we are given that the track radius is 500 m, and the tangential acceleration is 3.2 m/s^2 . Thus the tangential force is

$$
F_{\text{tan}} = ma_{\text{tan}} = (1100 \text{ kg})(3.2 \text{ m/s}^2) = 3.5 \times 10^3 \text{ N}.
$$

The centripetal force is given by
\n
$$
F_{\rm R} = m v^2 / r = (1100 \text{ kg})(15 \text{ m/s})^2 / (500 \text{ m}) = 5.0 \times 10^2 \text{ N}.
$$

26. The car has constant tangential acceleration, which is the acceleration that causes the speed to change. Thus use constant acceleration equations to calculate the tangential acceleration. The initial

speed is 0, the final speed is $320 \text{ km/h} \left(\frac{1.0 \text{ m/s}}{1.0 \text{ m/s}} \right) = 88.89 \text{ m/s}$, and the distance traveled is one half 3.6 km/h $\frac{1}{2}$, and the distance traveled is one half

of a circular arc of radius 220 m, so $\Delta x_{\text{tan}} = 220\pi$ m. Find the tangential acceleration using Eq. 2-11c.

$$
v_{\text{tan}}^2 - v_{\text{0 tan}}^2 = 2a_{\text{tan}}\Delta x_{\text{tan}} \rightarrow a_{\text{tan}} = \frac{v_{\text{tan}}^2 - v_{\text{0 tan}}^2}{2\Delta x_{\text{tan}}} = \frac{(88.89 \text{ m/s})^2}{2(220\pi \text{ m})} = 5.72 \text{ m/s}^2
$$

With this tangential acceleration, we can find the speed that the car has halfway through the turn, using Eq. 2-11c, and then calculate the radial acceleration.

\n $F_{x_1} = F_{x_2} + m_i v_i^2 / r_i = 4\pi m_i r_i f^2 + m_i (2\pi r_i f)^2 / r_i = \frac{4\pi^2 f^2 (m_i + m_i r_2)}{(m_i + m_i r_i)}$
\n $\text{for a line interval, with the terminal the radius of the circle, the heat has must fly as the\nof the direction. To just avoid erashing into the each, he must begin to form\ncircle (pull out of the device is\n $a_k = v^2 / r = 9.0g \rightarrow r = \frac{v^2}{9.0g} = \frac{(310 \text{m/s})^2}{9.0 (9.80 \text{m/s}^2)} = \frac{[1.1 \times 10^5 \text{m}]}{[1.1 \times 10^5 \text{m}]}$
\n $F_{\text{max}} = m a_{\text{sum}}$ = (1100 kg) (15 m/s)²/(500 m) = $\frac{[5.0 \times 10^2 \text{N}]}{[1.1 \times 10^5 \text{m}]}$
\n $F_{\text{max}} = m a_{\text{sum}}$ = (1100 kg) (15 m/s)²/(5$

The total acceleration is given by the Pythagorean combination of the tangential and centripetal accelerations. $a_{\text{total}} = \sqrt{a_{\text{R}}^2 + a_{\text{tan}}^2}$. If static friction is to provide the total acceleration, then accelerations. $a_{\text{total}} = \sqrt{a_R^2 + a_{\text{tan}}^2}$. If static friction is to provide the total acceleration, then
 $F_{\text{fr}} = ma_{\text{total}} = m\sqrt{a_R^2 + a_{\text{tan}}^2}$. We assume that the car is on the verge of slipping, and is on a level surface, and so the static frictional force has its maximum value of $F_f = \mu_s F_N = \mu_s mg$. If we equate these two expressions for the frictional force, we can solve for the coefficient of static friction.

$$
F_{\text{fr}} = ma_{\text{total}} = m\sqrt{a_{\text{R}}^2 + a_{\text{tan}}^2} = \mu_s mg \rightarrow
$$

$$
\mu_s = \frac{\sqrt{a_{\text{R}}^2 + a_{\text{tan}}^2}}{g} = \frac{\sqrt{(18.0 \text{ m/s}^2)^2 + (5.72 \text{ m/s}^2)^2}}{9.80 \text{ m/s}^2} = 1.92 \approx 1.9
$$

This is an exceptionally large coefficient of friction, and so the curve had better be banked.

27. We show a top view of the particle in circular motion, traveling \vec{a} clockwise. Because the particle is in circular motion, there must be a radially-inward component of the acceleration.

(a)
$$
a_R = a \sin \theta = v^2 / r \rightarrow
$$

\n $v = \sqrt{ar \sin \theta} = \sqrt{(1.05 \text{ m/s}^2)(2.90 \text{ m}) \sin 32.0^\circ} = \sqrt{1.27 \text{ m/s}}$

(*b*) The particle's speed change comes from the tangential acceleration, which is given by $a_{\text{tan}} = a \cos \theta$. If the tangential acceleration is

$$
\begin{array}{c|c}\n\overrightarrow{a}_{\tan} & \overrightarrow{a} \\
\hline\n\overrightarrow{b} & \overrightarrow{a} \\
\hline\n\overrightarrow{a} & \overrightarrow{b} \\
\hline\n\end{array}
$$

constant, then using Eq. 2-11a,
\n
$$
v_{\text{tan}} - v_{0 \text{ tan}} = a_{\text{tan}}t \rightarrow
$$

\n $v_{\text{tan}} = v_{0 \text{ tan}} + a_{\text{tan}}t = 1.27 \text{ m/s} + (1.05 \text{ m/s}^2)(\cos 32.0^\circ)(2.00 \text{ s}) = 3.05 \text{ m/s}$

28. The spacecraft is three times as far from the Earth's center as when at the surface of the Earth. Therefore, since the force as gravity decreases as the square of the distance, the force of gravity on the spacecraft will be one-ninth of its weight at the Earth's surface.

$$
F_G = \frac{1}{9} m g_{\text{Earth's}} = \frac{(1350 \text{ kg})(9.80 \text{ m/s}^2)}{9} = 1.47 \times 10^3 \text{ N}
$$

This could also have been found using Newton's law of Universal Gravitation.

- 29. (*a*) Mass is independent of location and so the mass of the ball is $\overline{21.0 \text{ kg}}$ on both the Earth and the planet.
	- (*b*) The weight is found by $W = mg$.

$$
W_{\text{Earth}} = mg_{\text{Earth}} = (21.0 \text{ kg})(9.80 \text{ m/s}^2) = 206 \text{ N}
$$

$$
W_{\text{Planet}} = mg_{\text{Planet}} = (21.0 \text{ kg})(12.0 \text{ m/s}^2) = 252 \text{ N}.
$$

30. The force of gravity on an object at the surface of a planet is given by Newton's law of Universal Gravitation, using the mass and radius of the planet. If that is the only force on an object, then the acceleration of a freely-falling object is acceleration due to gravity.

$$
F_G = G \frac{M_{\text{Moon}} m}{r_{\text{Moon}}^2} = m g_{\text{Moon}} \rightarrow
$$

.

$$
g_{\text{Moon}} = G \frac{M_{\text{Moon}}}{r_{\text{Moon}}^2} = \left(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2\right) \frac{\left(7.35 \times 10^{22} \text{ kg}\right)}{\left(1.74 \times 10^6 \text{ m}\right)^2} = 1.62 \text{ m/s}^2
$$

31. The acceleration due to gravity at any location on or above the surface of a planet is given by 2 $g_{\text{planet}} = G M_{\text{planet}} / r^2$, where *r* is the distance from the center of the planet to the location in question.

$$
g_{\text{planet}} = G \frac{M_{\text{Planet}}}{r^2} = G \frac{M_{\text{Earth}}}{(1.5R_{\text{Earth}})^2} = \frac{1}{1.5^2} G \frac{M_{\text{Earth}}}{R_{\text{Earth}}^2} = \frac{1}{1.5^2} g_{\text{Earth}} = \frac{9.8 \text{ m/s}^2}{1.5^2} = 4.4 \text{ m/s}^2
$$

32. The acceleration due to gravity at any location at or above the surface of a planet is given by 2 $g_{\text{planet}} = G M_{\text{planet}} / r^2$, where *r* is the distance from the center of the planet to the location in question.

$$
g_{\text{planet}} = G \frac{M_{\text{Planet}}}{r^2} = G \frac{1.66 M_{\text{Earth}}}{R_{\text{Earth}}^2} = 1.66 \left(G \frac{M_{\text{Earth}}}{R_{\text{Earth}}^2} \right) = 1.66 g_{\text{Earth}} = 1.66 \left(9.80 \text{ m/s}^2 \right) = 16.3 \text{ m/s}^2
$$

33. Assume that the two objects can be treated as point masses, with $m_1 = m$ and $m_2 = 4$ kg $-m$. The gravitational force between the two masses is given by \mathbb{R}^2 and \mathbb{R}^2 and

$$
F = G \frac{m_1 m_2}{r^2} = G \frac{m (4 - m)}{r^2} = (6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2) \frac{4m - m^2}{(0.25 \text{ m})^2} = 2.5 \times 10^{-10} \text{ N}.
$$

This can be rearranged into a quadratic form of $m^2 - 4m + 0.234 = 0$. Use the quadratic formula to solve for *m*, resulting in two values which are the two masses.

$$
m_1 = 3.9
$$
 kg, $m_2 = 0.1$ kg.

34. The acceleration due to gravity at any location at or above the surface of a planet is given by 2 $g_{\text{planet}} = G M_{\text{planet}} / r^2$, where *r* is the distance from the center of the planet to the location in question. For this problem, $M_{\text{Planet}} = M_{\text{Earth}} = 5.97 \times 10^{24} \text{ kg}$
(a) $r = R_{\text{total}} + 3200 \text{ m} - 6.38 \times 10^6 \text{ m} + 3200 \text{ m}$

(a)
$$
r = R_{\text{Earth}} + 3200 \text{ m} = 6.38 \times 10^6 \text{ m} + 3200 \text{ m}
$$

\n $g = G \frac{M_{\text{Earth}}}{r^2} = (6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2) \frac{(5.97 \times 10^{24} \text{ kg})}{(6.38 \times 10^6 \text{ m} + 3200 \text{ m})^2} = 9.77 \text{ m/s}^2$
\n(b) $r = R_{\text{Earth}} + 3200 \text{ km} = 6.38 \times 10^6 \text{ m} + 3.20 \times 10^6 \text{ m} = 9.58 \times 10^6 \text{ m}$

$$
g = G \frac{M_{\text{Earth}}}{r^2} = \left(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2\right) \frac{\left(5.97 \times 10^{24} \text{ kg}\right)}{\left(9.58 \times 10^6 \text{ m}\right)^2} = 4.34 \text{ m/s}^2
$$

35. In general, the acceleration due to gravity of the Earth is given by $g = GM_{\text{Earth}}/r^2$, where *r* is the distance from the center of the Earth to the location in question. So for the location in question,
 $g = \frac{1}{10} g_{\text{surface}} \rightarrow G \frac{M_{\text{Earth}}}{r^2} = \frac{1}{10} G \frac{M_{\text{Earth}}}{r^2} \rightarrow r^2 = 10 R_{\text{Earth}}^2$

$$
g = \frac{1}{10} g_{\text{surface}} \rightarrow G \frac{M_{\text{Earth}}}{r^2} = \frac{1}{10} G \frac{M_{\text{Earth}}}{R_{\text{Earth}}^2} \rightarrow r^2 = 10 R_{\text{Earth}}^2
$$

$$
r = \sqrt{10} R_{\text{Earth}} = \sqrt{10} (6.38 \times 10^6 \text{ m}) = 2.02 \times 10^7 \text{ m}
$$

36. The acceleration due to gravity at any location at or above the surface of a star is given by $g_{\text{star}} = G M_{\text{star}} / r^2$, where *r* is the distance from the center of the star to the location in question.

$$
g_{\text{star}} = G \frac{M_{\text{star}}}{r^2} = G \frac{5M_{\text{sun}}}{r^2} = \left(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2\right) \frac{5(1.99 \times 10^{30} \text{ kg})}{\left(1 \times 10^4 \text{ m}\right)^2} = \boxed{7 \times 10^{12} \text{ m/s}^2}
$$

37. The acceleration due to gravity at any location at or above the surface of a star is given by 2 $g_{\text{star}} = GM_{\text{star}}/r^2$, where *r* is the distance from the center of the star to the location in question.

$$
g_{\text{star}} = G \frac{M_{\text{sun}}}{R_{\text{Moon}}^2} = \left(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2\right) \frac{\left(1.99 \times 10^{30} \text{ kg}\right)}{\left(1.74 \times 10^6 \text{ m}\right)^2} = 4.38 \times 10^7 \text{ m/s}^2
$$

38. The distance from the Earth's center is $\frac{1}{6}$ 6 $\frac{28 \times 10^6 \text{ m}}{6}$ 6 $\frac{6.63 \times 10^6 \text{ m}}{6}$

 $r = R_{\text{Earth}} + 250 \text{ km} = 6.38 \times 10^6 \text{ m} + 2.5 \times 10^5 \text{ m} = 6.63 \times 10^6 \text{ m}.$

Calculate the acceleration due to gravity at that location.

$$
g = G \frac{M_{\text{Earth}}}{r^2} = G \frac{M_{\text{Earth}}}{r^2} = (6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2) \frac{5.97 \times 10^{24} \text{ kg}}{(6.63 \times 10^6 \text{ m})^2} = 9.059 \text{ m/s}^2
$$

$$
= 9.059 \text{ m/s}^2 \left(\frac{1'' g''}{9.80 \text{ m/s}^2}\right) = 0.924 g' \text{s}
$$

This is only about a 7.5% reduction from the value of *g* at the surface of the Earth.

39. Calculate the force on the sphere in the lower left corner, using the free body diagram shown. From the symmetry of the problem, the net forces in the *x* and *y* directions will be the same. Note $\theta = 45^{\circ}$

$$
F_x = F_{\text{right}} + F_{\text{dia}} \cos \theta = G \frac{m^2}{d^2} + G \frac{m^2}{(\sqrt{2}d)^2} \frac{1}{\sqrt{2}} = G \frac{m^2}{d^2} \left(1 + \frac{1}{2\sqrt{2}} \right)
$$

$$
F_{\text{up}} \left(\frac{1}{\sqrt{2}d} \right)
$$

 $\left(\frac{1}{2d} \right)^2 \sqrt{2}$ d^2 $\left(\frac{2\sqrt{2}}{2} \right)$ d^2 $\left(\frac{1}{2}\sqrt{2} \right)$ d^2 $(\sqrt{2}d)^2 \sqrt{2}$ d^2 $(2\sqrt{2})$ d^2 $(2\sqrt{2})$ d^2 d^2 $(2\sqrt{2})$ d^2 $(2\sqrt{2})$ and so $F_y = F_x = G \frac{m^2}{r^2} \left(1 + \frac{1}{2\sqrt{2}} \right)$. The net force can be found by the $\left(\frac{m}{m} \right)^{\frac{m}{2}}$ $1 + \frac{1}{\sqrt{m}}$. The net force can be found by the $\left(\frac{m}{\sqrt{m}}\right)^{6}$ (m)^V $2\sqrt{2}$ \int F_{right} $F_y = F_x = G \frac{m^2}{l^2} \left(1 + \frac{1}{2\sqrt{2}} \right)$. The net force can be found by the $\left(m \right)^{U}$ d^2 $\left(\begin{array}{c} 2\sqrt{2} \end{array} \right)$ Fight . The net force can be found by the $\frac{m}{E}$

Pythagorean combination of the two component forces. Due to the symmetry of the arrangement, the net force will be along the diagonal of the square.

dagram shown. From the symmetry of the problem, the net
\n
$$
\frac{F_x}{F_x} = F_{right} + F_{dia} \cos \theta = G \frac{m^2}{d^2} + G \frac{m^2}{(\sqrt{2}d)^2} \frac{1}{\sqrt{2}} = G \frac{m^2}{d^2} \left(1 + \frac{1}{2\sqrt{2}}\right)
$$

\n $F_{up} = F_x = G \frac{m^2}{d^2} \left(1 + \frac{1}{2\sqrt{2}}\right)$. The net force can be found by the
\nagorean combination of the two component forces. Due to the
\nmetry of the arrangement, the net force will be along the diagonal of the square.
\n $F = \sqrt{F_x^2 + F_y^2} = \sqrt{2F_x^2} = F_x \sqrt{2} = G \frac{m^2}{d^2} \left(1 + \frac{1}{2\sqrt{2}}\right) \sqrt{2} = G \frac{m^2}{d^2} \left(\sqrt{2} + \frac{1}{2}\right)$
\n $= \left(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2\right) \frac{(9.5 \text{ kg})^2}{(0.60 \text{ m})^2} \left(\sqrt{2} + \frac{1}{2}\right) = \frac{3.2 \times 10^{-8} \text{ N at } 45^{\circ}}{3.2 \times 10^{-8} \text{ N at } 45^{\circ}}$
\nforce points towards the center of the square.
\n $F_{right} = (150 - 108) \times 10^6 \text{ km} = 4.2 \times 10^{10} \text{ m}$ $F_{right} = (778 - 150) \times 10^6 \text{ km} = 6.28 \times 10^{11} \text{ m}$
\n $F_{right} = (1430 - 150) \times 10^6 \text{ km} = 1.28 \times 10^{12} \text{ m}$ $F_{center} = (778 - 150) \times 10^6 \text{ km} = 6.28 \times 10^{11} \text{ m}$

The force points towards the center of the square.

40. We are to calculate the force on Earth, so we need the distance of each planet from Earth.

$$
r_{\text{Earth}} = (150 - 108) \times 10^6 \text{ km} = 4.2 \times 10^{10} \text{ m}
$$

\n
$$
r_{\text{Earth}} = (778 - 150) \times 10^6 \text{ km} = 6.28 \times 10^{11} \text{ m}
$$

\n
$$
r_{\text{Earth}} = (1430 - 150) \times 10^6 \text{ km} = 1.28 \times 10^{12} \text{ m}
$$

\n
$$
r_{\text{Earth}} = (1430 - 150) \times 10^6 \text{ km} = 1.28 \times 10^{12} \text{ m}
$$

Jupiter and Saturn will exert a rightward force, while Venus will exert a leftward force. Take the right direction as positive.

$$
F_{\text{Earth}\atop\text{planets}} = G \frac{M_{\text{Earth}} M_{\text{Jupiter}}}{r_{\text{Earth}}^2} + G \frac{M_{\text{Earth}} M_{\text{Saturn}}}{r_{\text{Earth}}^2} - G \frac{M_{\text{Earth}} M_{\text{Venus}}}{r_{\text{Earth}}^2}
$$

= $GM_{\text{Earth}}^2 \left(\frac{318}{(6.28 \times 10^{11} \text{ m})^2} + \frac{95.1}{(1.28 \times 10^{12} \text{ m})^2} - \frac{0.815}{(4.2 \times 10^{10} \text{ m})^2} \right)$
= $(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2) (5.97 \times 10^{24} \text{ kg})^2 (4.02 \times 10^{-22} \text{ m}^{-2}) = 9.56 \times 10^{17} \text{ N}$

The force of the Sun on the Earth is as follows.

$$
F_{\text{Earth.}} = G \frac{M_{\text{Earth}} M_{\text{Sun}}}{r_{\text{Earth}}^2} = \left(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2\right) \frac{\left(5.97 \times 10^{24} \text{ kg}\right)\left(1.99 \times 10^{30} \text{ kg}\right)}{\left(1.50 \times 10^{11} \text{ m}\right)^2} = 3.52 \times 10^{22} \text{ N}
$$

And so the ratio is $F_{\text{Earth}} = 9.56 \times 10^{17} \text{ N} / 3.52 \times 10^{22} \text{ N} = 2.71 \times 10^{-5}$, which is 27 millionths.

41. The expression for the acceleration due to gravity at the surface of a body is $g_{\text{body}} = G \frac{M_{\text{body}}}{R_{\text{beam}}^2}$, where $_{\text{body}}$ – $_{\text{D}^2}$, where body $M_{\rm body}$ $g_{\text{body}} = G \frac{\text{body}}{\sqrt{2}}$, where R_{body}^2 , where

 R_{body} is the radius of the body. For Mars, $g_{\text{Mars}} = 0.38 g_{\text{Earth}}$. Thus

is the radius of the body. For Mars,
$$
g_{\text{Mars}} = 0.38 g_{\text{Earth}}
$$
. Thus
\n
$$
G \frac{M_{\text{Mars}}}{R_{\text{Mars}}^2} = 0.38 G \frac{M_{\text{Earth}}}{R_{\text{Earth}}^2} \rightarrow
$$
\n
$$
M_{\text{Mars}} = 0.38 M_{\text{Earth}} \left(\frac{R_{\text{Mars}}}{R_{\text{Earth}}}\right)^2 = 0.38 \left(5.97 \times 10^{24} \text{ kg}\right) \left(\frac{3400 \text{ km}}{6380 \text{ km}}\right)^2 = 6.4 \times 10^{23} \text{ kg}
$$

42. The speed of an object in an orbit of radius *r* around the Sun is given by $v = \sqrt{GM_{sun}/r}$, and is also given by $v = 2\pi r/T$, where T is the period of the object in orbit. Equate the two expressions for the speed and solve for M_{Sun} , using data for the Earth.

$$
\sqrt{G\frac{M_{\text{Sun}}}{r}} = \frac{2\pi r}{T} \rightarrow M_{\text{Sun}} = \frac{4\pi^2 r^3}{GT^2} = \frac{4\pi^2 \left(1.50 \times 10^{11} \text{ m}\right)^3}{\left(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2\right) \left(3.15 \times 10^7 \text{ sec}\right)^2} = 2.01 \times 10^{30} \text{ kg}
$$

This is the same result obtained in Example 5-16 using Kepler's third law.

43. The speed of a satellite in a circular orbit around a body is given by $v = \sqrt{GM_{\text{body}}/r}$, where *r* is the distance from the satellite to the center of the body. So for this satellite,

$$
v = \sqrt{G \frac{M_{\text{body}}}{r}} = \sqrt{G \frac{M_{\text{Earth}}}{R_{\text{Earth}} + 3.6 \times 10^6 \text{ m}}} = \sqrt{(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2) \frac{(5.97 \times 10^{24} \text{ kg})}{(9.98 \times 10^6 \text{ m})}}
$$

= $6.32 \times 10^3 \text{ m/s}$

44. The shuttle must be moving at "orbit speed" in order for the satellite to remain in the orbit when released. The speed of a satellite in circular orbit around the Earth is given by

$$
v = \sqrt{G \frac{M_{\text{Earth}}}{r}} = \sqrt{G \frac{M_{\text{Earth}}}{(R_{\text{Earth}} + 650 \text{ km})}} = \sqrt{(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2) \frac{(5.97 \times 10^{24} \text{ kg})}{(6.38 \times 10^6 \text{ m} + 6.5 \times 10^5 \text{ m})}}
$$

=
$$
7.53 \times 10^3 \text{ m/s}
$$

45. The centripetal acceleration will simulate gravity. Thus $v^2/r = 0.60g \rightarrow v = \sqrt{0.60gr}$. Also for a rotating object, the speed is given by $v = 2\pi r/T$. Equate the two expressions for the speed and solve for the period.

$$
v = \sqrt{0.60gr} = \frac{2\pi r}{T}
$$
 \rightarrow $T = \frac{2\pi r}{\sqrt{0.60gr}} = \frac{2\pi (16 \text{ m})}{\sqrt{(0.60)(9.8 \text{ m/s}^2)(16 \text{ m})}} = 10 \text{ sec}$

46. The speed of an object in an orbit of radius *r* around the Earth is given by $v = \sqrt{GM_{\text{Earth}}/r}$, and is also given by $v = 2\pi r/T$, where T is the period of the object in orbit. Equate the two expressions for the speed and solve for *T*. Also, for a "near-Earth" orbit, $r = R_{\text{cont}}$.

$$
\sqrt{G \frac{M_{\text{Earth}}}{r}} = \frac{2\pi r}{T} \rightarrow T = 2\pi \sqrt{\frac{r^3}{GM_{\text{Earth}}}}
$$

$$
T = 2\pi \sqrt{\frac{R_{\text{Earth}}^3}{GM_{\text{Earth}}}} = 2\pi \sqrt{\frac{(6.38 \times 10^6 \text{ m})^3}{(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2)(5.98 \times 10^{24} \text{ m})}} = \boxed{5070 \text{ s} \sim 84 \text{ min}}
$$

No, the result does not depend on the mass of the satellite.

47. At the top of Mt. Everest (elevation 8848 meters), the distance of the orbit from the center of the Earth would be $r = R_{\text{Earth}} + 8848 \text{ m} = 6.38 \times 10^6 \text{ m} + 8848 \text{ m}$. The orbit speed is given by

$$
v = \sqrt{G \frac{M_{\text{Earth}}}{r}} = \sqrt{(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2) \frac{(5.98 \times 10^{24} \text{ m})}{(6.38 \times 10^6 \text{ m} + 8848 \text{ m})}} = 7.90 \times 10^3 \text{ m/s}.
$$

A comment – a launch would have some initial orbit speed from the fact that the Earth is rotating to the east. That is why most space launches are to the east.

48. The speed of an object in an orbit of radius *r* around the Moon is given by $v = \sqrt{GM_{\text{Moon}}/r}$, and is also given by $v = 2\pi r/T$, where T is the period of the object in orbit. Equate the two expressions

for the speed and solve for T.
\n
$$
\sqrt{GM_{\text{Moon}}/r} = 2\pi r/T \rightarrow
$$
\n
$$
T = 2\pi \sqrt{\frac{r^3}{GM_{\text{Moon}}}} = 2\pi \sqrt{\frac{(R_{\text{Moon}} + 100 \text{ km})^3}{GM_{\text{Moon}}}} = 2\pi \sqrt{\frac{(1.74 \times 10^6 \text{ m} + 1.0 \times 10^5 \text{ m})^3}{(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2)(7.35 \times 10^{22} \text{ kg})}}
$$
\n
$$
= 7.08 \times 10^3 \text{ s} (-2 \text{ h})
$$

 \vec{F}_{N} *m***g**

 \mathbf{F}_{N} $m\mathbf{g}$

49. The speed of an object in an orbit of radius *r* around a planet is given by $v = \sqrt{GM_{\text{n^{short}}}/r}$, and is also given by $v = 2\pi r/T$, where T is the period of the object in orbit. Equate the two expressions for the speed and solve for *T*.

$$
\sqrt{G\frac{M_{\text{Planet}}}{r}} = \frac{2\pi r}{T} \rightarrow T = 2\pi \sqrt{\frac{r^3}{GM_{\text{Planet}}}}
$$

For this problem, the inner orbit is at $r_{\text{inner}} = 7.3 \times 10^7 \text{ m}$, and the outer orbit is at $r_{\text{inner}} = 1.7 \times 10^8 \text{ m}$. For this problem, the inner orbit is at $r_{\text{inner}} = 7.3 \times 10^{7}$ m, and the outer orbit is at $r_{\text{inner}} = 1.7 \times 10^{8}$ m.
Use these values to calculate the periods.

$$
T_{\text{inner}} = 2\pi \sqrt{\frac{\left(7.3 \times 10^7 \,\mathrm{m}\right)^3}{\left(6.67 \times 10^{-11} \,\mathrm{N} \cdot \mathrm{m}^2/\mathrm{kg}^2\right) \left(5.7 \times 10^{26} \,\mathrm{kg}\right)}} = \boxed{2.0 \times 10^4 \,\mathrm{s}}
$$
\n
$$
T_{\text{outer}} = 2\pi \sqrt{\frac{\left(1.7 \times 10^8 \,\mathrm{m}\right)^3}{\left(6.67 \times 10^{-11} \,\mathrm{N} \cdot \mathrm{m}^2/\mathrm{kg}^2\right) \left(5.7 \times 10^{26} \,\mathrm{kg}\right)}} = \boxed{7.1 \times 10^4 \,\mathrm{s}}
$$

Saturn's rotation period (day) is 10 hr 39 min which is about 3.8×10^4 sec. Thus the inner ring will appear to move across the sky "faster" than the Sun (about twice per Saturn day), while the outer ring will appear to move across the sky "slower" than the Sun (about once every two Saturn days).

- 50. The apparent weight is the normal force on the passenger. For a person at rest, the normal force is equal to the actual weight. If there is acceleration in the vertical direction, either up or down, then the normal force (and hence the apparent weight) will be different than the actual weight. The speed of the Ferris wheel is $v = 2\pi r/T = 2\pi (12.0 \text{ m})/15.5 \text{ s} = 4.86 \text{ m/s}.$
	- (*a*) At the top, consider the free-body diagram shown. We assume the passengers are right-side up, so that the normal force of the Ferris wheel seat is upward. The net force must point to the center of the circle, so write Newton's $2nd$ law with downward as the positive direction. The acceleration is \vec{F}_{N} | $m\vec{g}$ centripetal since the passengers are moving in a circle.

$$
\sum F = F_{\rm R} = mg - F_{\rm N} = ma = mv^2 / r \rightarrow F_{\rm N} = mg - mv^2 / r
$$

The ratio of apparent weight to real weight is given by
 $\frac{m_2^2}{\mu} = 2 \frac{2^2}{\mu} = \frac{2^2}{\mu^2} = \frac{(4.86 \text{ m/s})^2}{\mu} = \frac{2^2}{\mu} = \frac{2^2}{\mu} = 2 \text{ m}^2$

$$
\frac{mg - mv^2/r}{mg} = \frac{g - v^2/r}{g} = 1 - \frac{v^2}{rg} = 1 - \frac{(4.86 \text{ m/s})^2}{(12.0 \text{ m})(9.80 \text{ m/s}^2)} = \boxed{0.799}
$$

(*b*) At the bottom, consider the free-body diagram shown. We assume the passengers are right-side up, so that the normal force of the Ferris wheel seat is upward. The net force must point to the center of the circle, so write Newton's $2nd$ law with upward as the positive direction. The acceleration is centripetal since the passengers are moving in a circle.

$$
\sum F = F_{R} = F_{N} - mg = ma = mv^{2}/r \rightarrow F_{N} = mg + mv^{2}/r
$$

The ratio of apparent weight to real weight is given by

$$
\frac{mg + mv^2/r}{mg} = 1 + \frac{v^2}{rg} = \boxed{1.201}
$$

51. Consider the free-body diagram for the astronaut in the space vehicle. The Moon is below the astronaut in the figure. We assume that the astronaut is touching the inside of the space vehicle, or in a seat, or strapped in somehow, and so a force will be exerted on the astronaut by the spacecraft. That force has been labeled \vec{F}_s . The magnitude of \vec{F}_n . The magnitude of \vec{F} , \vec{F} , $m\vec{\sigma}$ that force is the apparent weight of the astronaut. Take down as the positive direction.

 $0 \rightarrow$

 $F = mg - F_N = 0 \rightarrow$

N

 \vec{F}_{N} $m\vec{g}$

(*a*) If the spacecraft is moving with a constant velocity, then the acceleration of the astronaut must be 0, and so the net force on the astronaut is 0.

$$
F_{_{N}} = mg = G \frac{mM_{_{\text{Moon}}}}{r^{2}} = \left(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^{2} \middle/ \text{kg}^{2}\right) \frac{(75 \text{ kg})\left(7.4 \times 10^{22} \text{ kg}\right)}{\left(4.2 \times 10^{6} \text{ m}\right)^{2}} = 21 \text{ N}
$$

Since the value here is positive, the normal force points in the original direction as shown on the free-body diagram. The astronaut will be pushed "upward" by the floor or the seat. Thus the astronaut will perceive that he has a "weight" of $\boxed{21 \text{ N}$, towards the Moon.

(*b*) Now the astronaut has an acceleration towards the Moon. Write Newton's $2nd$ law for the astronaut, with down as the positive direction.

$$
\sum F = mg - F_v = ma \rightarrow F_v = mg - ma = 21 \text{ N} - (75 \text{ kg})(2.9 \text{ m/s}^2) = -2.0 \times 10^2 \text{ N}
$$

Because of the negative value, the normal force points in the opposite direction from what is shown on the free-body diagram – it is pointing towards the Moon. So perhaps the astronaut is pinned against the "ceiling" of the spacecraft, or safety belts are pulling down on the astronaut. The astronaut will perceive being "pushed downwards", and so has an upward apparent weight of $\left[2.0 \times 10^2 \text{ N} \right]$, away from the Moon 2.0×10^2 N, away from the Moon...

52. Consider the motion of one of the stars. The gravitational force on the star is given by $F = G \frac{mm}{d^2}$,
where d is the distance separating the two stars. But since the star is moving in a circle of radius $d/2$, $F = G \frac{mm}{r^2}$, d^2 and d^2 and the force on the star can be expressed as $F_p = mv^2/r = m \frac{v^2}{r}$. Equate these two force expressions, $\frac{d}{2}$. Equation these two force expressions, $F_R = m v^2 / r = m \frac{v^2}{r}$. Equate these two force expressions, $d/2$ **d** . Equate these two force expressions, and use $v = 2\pi r/T = d\pi/T$.

$$
G\frac{mm}{d^2} = m\frac{v^2}{d/2} = m\frac{(d\pi/T)^2}{d/2} \rightarrow
$$

\n
$$
m = \frac{2\pi^2 d^3}{GT^2} = \frac{2\pi^2 (3.6 \times 10^{11} \text{ m})^3}{(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2) \left[(5.7 \text{ y}) (3.15 \times 10^7 \text{ sec/y}) \right]^2} = 4.3 \times 10^{29} \text{ kg}
$$

$$
\overline{53}
$$

53. Consider a free-body diagram for the woman in the elevator. \mathbf{F}_{N} is the force the spring scale exerts. Write Newton's $2nd$ law for the vertical direction, with up as positive.

$$
\sum F = F_{\rm N} - mg = ma \rightarrow F_{\rm N} = m(g + a)
$$

 (a, b) For constant speed motion in a straight line, the acceleration is 0, and so

$$
F_{N} = mg = (55 \text{ kg})(9.8 \text{ m/s}^{2}) = 5.4 \times 10^{2} \text{ N}
$$

(c) Here $a = +0.33g$ and so $F_{N} = 1.33mg = 1.33(55 \text{ kg})(9.8 \text{ m/s}^{2}) = 7.2 \times 10^{2} \text{ N}$

(*d*) Here $a = -0.33g$ and so $F_N = 0.67 mg = 0.67 (55 kg)(9.8 m/s²) = 3.6 \times 10² N$

(e) Here
$$
a = -g
$$
 and so $F_N = 0 N$

54. Draw a free-body diagram of the monkey. Then write Newton's $2nd$ law for the vertical direction, with up as positive.

$$
\sum F = F_{\rm T} - mg = ma \rightarrow a = \frac{F_{\rm T} - mg}{m}
$$

For the maximum tension of 220 N,

220 N, $(17.0 \text{ kg})(0.80 \text{ m/s}^2)$

$$
a = \frac{220 \text{ N} - (17.0 \text{ kg})(9.80 \text{ m/s}^2)}{(17.0 \text{ kg})} = 3.1 \text{ m/s}^2
$$

Thus the elevator must have an upward acceleration greater than $a = 3.1 \text{ m/s}^2$ for the cord to break. $a = 3.1 \text{ m/s}^2$ for the cord to break. Any downward acceleration would result in a tension less than the monkey's weight.

55. (*a*) The speed of an object in near-surface orbit around a planet is given by $v = \sqrt{GM/R}$, where *M* is the planet mass and *R* is the planet radius. The speed is also given by $v = 2\pi R/T$, where *T* is the period of the object in orbit. Equate the two expressions for the speed.

$$
\sqrt{G\frac{M}{R}} = \frac{2\pi R}{T} \rightarrow G\frac{M}{R} = \frac{4\pi^2 R^2}{T^2} \rightarrow \frac{M}{R^3} = \frac{4\pi^2}{GT^2}
$$

The density of a uniform spherical planet is given by $\rho = \frac{M}{\text{Volume}} = \frac{M}{\frac{4}{3}\pi R^3}$. Thus *R*

$$
\rho = \frac{3M}{4\pi R^3} = \frac{3}{4\pi} \frac{4\pi^2}{GT^2} = \frac{3\pi}{GT^2}
$$

(b) For Earth,

$$
\rho = \frac{3\pi}{GT^2} = \frac{3\pi}{(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2) [(85 \text{ min})(60 \text{ s/min})]^2} = 5.4 \times 10^3 \text{ kg/m}^3
$$

56. Use Kepler's $3rd$ law for objects orbiting the Earth. The following are given.

$$
T_2
$$
 = period of Moon = (27.4 day) $\left(\frac{86,400 \text{ s}}{1 \text{ day}}\right)$ = 2.367 × 10⁶ sec

$$
r_2
$$
 = radius of Moon's orbit = 3.84×10⁸ m

$$
r_1
$$
 = radius of near-Earth orbit = R_{Earth} = 6.38×10⁶ m

$$
(T_1/T_2)^2 = (r_1/r_2)^3 \rightarrow
$$

\n
$$
T_1 = T_2 (r_1/r_2)^{3/2} = (2.367 \times 10^6 \text{ sec}) \left(\frac{6.38 \times 10^6 \text{ m}}{3.84 \times 10^8 \text{ m}} \right)^{3/2} = 5.07 \times 10^3 \text{ sec} \left[(-84.5 \text{ min}) \right]
$$

57. Use Kepler's 3rd law for objects orbiting the Sun.
\n
$$
\left(\frac{r_{\text{Larns}}}{r_{\text{Earth}}}\right)^3 = \left(\frac{T_{\text{Larns}}}{T_{\text{Earth}}}\right)^2 \rightarrow r_{\text{Larns}} = r_{\text{Earth}} \left(\frac{T_{\text{Larns}}}{T_{\text{Earth}}}\right)^{2/3} = \left(1.50 \times 10^{11} \text{ m}\right) \left(\frac{410 \text{ d}}{365 \text{ d}}\right)^{2/3} = \boxed{1.62 \times 10^{11} \text{ m}}
$$

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

58. Use Kepler's $3rd$ law for objects orbiting the Sun.

$$
\left(T_{\text{Neptune}}/T_{\text{Earth}}\right)^2 = \left(r_{\text{Neptune}}/r_{\text{Earth}}\right)^3 \rightarrow
$$
\n
$$
T_{\text{Neptune}} = T_{\text{Earth}} \left(\frac{r_{\text{Neptune}}}{r_{\text{Earth}}}\right)^{3/2} = \left(1 \text{ year}\right) \left(\frac{4.5 \times 10^9 \text{ km}}{1.5 \times 10^8 \text{ km}}\right)^{3/2} = \boxed{1.6 \times 10^2 \text{ years}}
$$

59. Use Kepler's 3rd law to relate the orbits of Earth and Halley's comet around the Sun.

$$
\left(r_{\text{Halley}}/r_{\text{Earth}}\right)^3 = \left(T_{\text{Halley}}/T_{\text{Earth}}\right)^2 \rightarrow
$$
\n
$$
r_{\text{Halley}} = r_{\text{Earth}} \left(T_{\text{Halley}}/T_{\text{Earth}}\right)^{2/3} = \left(150 \times 10^6 \,\text{km}\right) \left(76 \,\text{y/1 y}\right)^{2/3} = 2690 \times 10^6 \,\text{km}
$$

This value is half the sum of the nearest and farthest distances of Halley's comet from the Sun. Since the nearest distance is very close to the Sun, we will approximate that nearest distance as 0. Then the farthest distance is twice the value above, or 5380×10^6 km. This distance approaches the mean orbit distance of Pluto, which is 5900×10^6 km. It is still in the Solar System, nearest to Pluto's orbit.

60. There are two expressions for the velocity of an object in circular motion around a mass *M*:

$$
v = \sqrt{GM/r} \text{ and } v = 2\pi r/T. \text{ Equate the two expressions and solve for } T.
$$

\n
$$
\sqrt{GM/r} = 2\pi r/T \rightarrow
$$

\n
$$
T = 2\pi \sqrt{\frac{r^3}{GM}} = 2\pi \sqrt{\frac{((3 \times 10^4 \text{ ly}) \frac{(3 \times 10^8 \text{ m/s})(3.16 \times 10^7 \text{ sec})}{1 \text{ ly}})}{(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2)(4 \times 10^{41} \text{ kg})}} = 5.8 \times 10^{15} \text{ s} = 1.8 \times 10^8 \text{ y}
$$

\n
$$
\approx 2 \times 10^8 \text{ y}
$$

61. (*a*) The relationship between satellite period *T*, mean satellite distance *r*, and planet mass *M* can be derived from the two expressions for satellite speed: $v = \sqrt{GM/r}$ and $v = 2\pi r/T$. Equate the two expressions and solve for *M*.

$$
\sqrt{GM/r} = 2\pi r/T \quad \rightarrow \quad M = \frac{4\pi^2 r^3}{GT^2}
$$

Substitute the values for Io to get the mass of Jupiter.

$$
M_{\text{Jupiter}} = \frac{4\pi^2 \left(4.22 \times 10^8 \text{ m}\right)^3}{\left(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2\right) \left(1.77 \text{d} \times \frac{24 \text{ h}}{1 \text{ d}} \times \frac{3600 \text{ s}}{1 \text{ h}}\right)^2} = 1.90 \times 10^{27} \text{ kg}.
$$

(*b*) For the other moons:

$$
M_{\text{Jupiter-}} = \frac{4\pi^2 \left(6.71 \times 10^8 \text{ m}\right)^3}{\left(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2\right) \left(3.55 \times 24 \times 3600 \text{ s}\right)^2} = 1.90 \times 10^{27} \text{ kg}
$$

$$
M_{\text{Jupiter-}} = \frac{4\pi^2 \left(1.07 \times 10^9 \text{ m}\right)^3}{\left(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2\right) \left(7.16 \times 24 \times 3600 \text{ s}\right)^2} = 1.89 \times 10^{27} \text{ kg}
$$

$$
M_{\text{Jupiter}} = \frac{4\pi^2 \left(1.883 \times 10^9 \text{ m}\right)^3}{\left(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2\right) \left(16.7 \times 24 \times 3600 \text{ s}\right)^2} = 1.90 \times 10^{27} \text{ kg}
$$

 Yes , the results are consistent – only about 0.5% difference between them.

- 62. Knowing the period of the Moon and the distance to the Moon, we can calculate the speed of the Moon by $v = 2\pi r/T$. But the speed can also be calculated for any Earth satellite by
 $v = \sqrt{GM_{\text{Earth}}/r}$. Equate the two expressions for the speed, and solve for the mass of the Earth.
	- Earth / \sim 2*n*, \sim 7 2.3 $4\pi^2 \left(3.84 \times 10^8 \text{ m}\right)^3$ 241_{ref} $\frac{\text{Earth}}{2}$ $\frac{C T^2}{L^2}$ $\left(6.67 \times 10^{-11} \text{ N} \text{ m}^2/\text{kg}^2\right) \left[(27.4 \text{ A}) (96.400 \text{ s/s})\right]^2$ $\frac{2.50 \times 10^{-19} \text{ kg}}{2.50 \times 10^{-19} \text{ kg}}$ $2\pi r/T \rightarrow$ $4\pi^2 r^3$ $4\pi^2 (3.84 \times 10^8 \text{ m})$ $\frac{1}{2}$ $\frac{10^{24}1}{2}$ 5.98×10^{24} kg GM_{Earth} $\left(r = 2\pi r \right)T \rightarrow$ $M_{\text{Earth}} = \frac{4\pi^2 r^3}{r^2} = \frac{4\pi^2 (3.84 \times 10^9 \text{ m})}{(1.00 \times 10^9 \text{ m})} = 5.98 \times 10^{24} \text{ kg}$
- 63. Use Kepler's 3^{rd} law to find the radius of each moon of Jupiter, using Io's data for r_2 and T_2 .

$$
(r_1/r_2)^3 = (T_1/T_2)^2 \rightarrow r_1 = r_2 (T_1/T_2)^{2/3}
$$

\n
$$
r_{\text{Europa}} = r_{\text{lo}} (T_{\text{Europa}}/T_{\text{lo}})^{2/3} = (422 \times 10^3 \text{ km}) (3.55 \text{ d}/1.77 \text{ d})^{2/3} = \boxed{671 \times 10^3 \text{ km}}
$$

\n
$$
r_{\text{Ganymede}} = (422 \times 10^3 \text{ km}) (7.16 \text{ d}/1.77 \text{ d})^{2/3} = \boxed{1070 \times 10^3 \text{ km}}
$$

\n
$$
r_{\text{Calisto}} = (422 \times 10^3 \text{ km}) (16.7 \text{ d}/1.77 \text{ d})^{2/3} = \boxed{1880 \times 10^3 \text{ km}}
$$

The agreement with the data in the table is excellent.

64. (*a*) Use Kepler's 3rd law to relate the Earth and the hypothetical planet in their orbits around the Sun.

$$
\left(T_{\text{planet}}/T_{\text{Earth}}\right)^2 = \left(r_{\text{planet}}/r_{\text{Earth}}\right)^3 \quad \rightarrow \quad T_{\text{planet}} = T_{\text{Earth}}\left(r_{\text{planet}}/r_{\text{Earth}}\right)^{3/2} = \left(1 \text{ y}\right)\left(3/1\right)^{3/2} \approx \boxed{5 \text{ y}}
$$

- (*b*) No mass data can be calculated from this relationship, because the relationship is massindependent. Any object at the orbit radius of 3 times the Earth's orbit radius would have a period of 5.2 years, regardless of its mass.
- 65. If the ring is to produce an apparent gravity equivalent to that of Earth, then the normal force of the ring on objects must be given by $F_N = mg$. The Sun will also exert a force on objects on the ring. $\overrightarrow{F_N} = mg$. Sun See the free-body diagram.

Write Newton's $2nd$ law for the object, with the fact that the acceleration is centripetal.

$$
\sum F = F_{\rm g} = F_{\rm sun} + F_{\rm N} = m v^2 / r
$$

 $6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2$ $((27.4 \text{ d})(86,400 \text{ s/d}))^2$

 GT^2 $(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2)$ $[(27.4 \text{ d})(86,400 \text{ s/d})]^2$

Substitute in the relationships that $v = 2\pi r/T$, $F_N = mg$, and $F_{Sun} = G \frac{1.7 \text{ m} \cdot \text{s}}{2}$, and solve for the *mg*, and $F_{\text{Sun}} = G \frac{M_{\text{Sun}} m}{r^2}$, and solve for the r^2 period of the rotation.

$$
F_{\text{Sun}} + F_{\text{N}} = m v^2 / r \rightarrow G \frac{M_{\text{Sun}} m}{r^2} + mg = \frac{4 \pi^2 m r}{T^2} \rightarrow G \frac{M_{\text{Sun}}}{r^2} + g = \frac{4 \pi^2 r}{T^2}
$$

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$
T = \sqrt{\frac{4\pi^2 r}{G\frac{M_{\text{Sun}}}{r^2} + g}} = \sqrt{\frac{4\pi^2 \left(1.50 \times 10^{11} \text{ m}\right)}{\left(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2\right) \frac{\left(1.99 \times 10^{30} \text{ kg}\right)}{\left(1.50 \times 10^{11} \text{ m}\right)^2} + 9.8 \text{ m/s}^2}} = 7.8 \times 10^5 \text{ s} = 9.0 \text{ d}
$$

The force of the Sun is only about 1/1600 the size of the normal force. The force of the Sun could have been ignored in the calculation with no effect in the result as given above.

66. A free-body diagram of Tarzan at the bottom of his swing is shown. The upward tension force is created by his pulling down on the vine. Write Newton's $2nd$ law in the vertical direction. Since he is moving in a circle, his acceleration will be centripetal, and points upward when he is at the bottom.

$$
\sum F = F_{\rm T} - mg = ma = mv^2/r \rightarrow v = \sqrt{\frac{(F_{\rm T} - mg)r}{m}}
$$

 $F_r - mg$ *r* $\qquad \qquad \blacksquare$ m *m***g** \mathbf{F}_{T}

The maximum speed will be obtained with the maximum tension.

$$
v_{\text{max}} = \sqrt{\frac{(\vec{F}_{\text{T max}} - mg)r}{m}} = \sqrt{\frac{(1400 \text{ N} - (80 \text{ kg})(9.8 \text{ m/s}^2))5.5 \text{ m}}{80 \text{ kg}}} = \boxed{6.5 \text{ m/s}}
$$

67. The acceleration due to the Earth's gravity at a location at or above the surface is given by 2 $g = GM_{\text{Earth}}/r^2$, where *r* is the distance from the center of the Earth to the location in question. Find the location where $g = \frac{1}{2} g_{\text{surface}}$. $g = \frac{1}{2} g_{\text{surface}}$.

$$
\frac{GM_{\text{Earth}}}{r^2} = \frac{1}{2} \frac{GM_{\text{Earth}}}{R_{\text{Earth}}^2} \rightarrow r^2 = 2R_{\text{Earth}}^2 \rightarrow r = \sqrt{2}R_{\text{Earth}}
$$

The distance above the Earth's surface is
\n
$$
r - R_{\text{Earth}} = (\sqrt{2} - 1)R_{\text{Earth}} = (\sqrt{2} - 1)(6.38 \times 10^6 \text{ m}) = 2.64 \times 10^6 \text{ m}.
$$

68. The radius of either skater's motion is 0.80 m, and the period is 2.5 sec. Thus their speed is given by $2\pi r/T = \frac{2\pi (0.80 \text{ m})}{r} = 2.0 \text{ m/s}$. Since each skater is moving in a circle, the net radial force on $2.5 s$ $v = 2\pi r/T = \frac{2\pi (1000 \text{ m})}{r} = 2.0 \text{ m/s}$. Since each skater is moving in a circle, the net radial force on each one is given by Eq. 5-3.

$$
F_{\rm R} = m v^2 / r = \frac{(60.0 \text{ kg})(2.0 \text{ m/s})^2}{0.80 \text{ m}} = 3.0 \times 10^2 \text{ N}.
$$

69. Consider this free-body diagram for an object at the equator. Since the object is moving in a circular path, there must be a net force on the object, pointing towards the center of the Earth, producing a centripetal acceleration. Write Newton's 2^{nd} law, with the inward direction positive.

$$
\sum F_{\rm R} = mg - F_{\rm N} = m v^2 / R_{\rm Earth} \rightarrow F_{\rm N} = m (g - v^2 / R_{\rm Earth})
$$

We see that the normal force, which without the rotation would be the "expected" value of *mg*, has now been reduced. This effect can be described as saying that the acceleration due to gravity has been reduced, by an amount equal to v^2/R_{Earth} . To calculate this

"change" in *g*, use $v = 2\pi R_{\text{Earth}}/T$ to get the following.

 $\mathbf{F}_{\textrm{\tiny N}}$

 \vec{F}_{N} | $m\vec{g}$

$$
\Delta g = -v^2/R_{\text{Earth}} = -\frac{4\pi^2 R_{\text{Earth}}}{T^2} = -\frac{4\pi^2 (6.38 \times 10^6 \text{ m})}{\left[(1 \text{ d}) (86,400 \text{ s}/1 \text{ d}) \right]^2} = -0.03374 \text{ m/s}^2
$$

This is a reduction of -0.03374 m/s² x $\frac{1 g}{9.80 \text{ m/s}^2} = -3.44 \times 10^{-3} g$.

70. For the forces to balance means that \overline{d} spacecraft due to the Earth must be \int Earth spacecraft, equate them, and solve for the distance *x*.

$$
F_{\text{Earth}} = G \frac{M_{\text{Earth}} m_{\text{spacerah}}}{x^2} \qquad ; \qquad F_{\text{Moon}} = G \frac{M_{\text{Moon}} m_{\text{spacerah}}}{(d-x)^2}
$$
\n
$$
G \frac{M_{\text{Earth}} m_{\text{spacerah}}}{x^2} = G \frac{M_{\text{Moon}} m_{\text{spacerah}}}{(d-x)^2} \qquad \rightarrow \qquad \frac{x^2}{M_{\text{Earth}}} = \frac{(d-x)^2}{M_{\text{Moon}}} \qquad \rightarrow \qquad \frac{x}{\sqrt{M_{\text{Earth}}}} = \frac{d-x}{\sqrt{M_{\text{Moon}}}}
$$
\n
$$
x = d \frac{\sqrt{M_{\text{Earth}}}}{\sqrt{M_{\text{Moon}}} + \sqrt{M_{\text{Earth}}}} = (3.84 \times 10^8 \text{ m}) \frac{\sqrt{5.97 \times 10^{24} \text{ kg}}}{\sqrt{5.97 \times 10^{24} \text{ kg}}} = \frac{3.46 \times 10^8 \text{ m}}{3.46 \times 10^8 \text{ m}}
$$

This is only about 22 Moon radii away from the Moon.

71. Consider a free-body diagram of yourself in the elevator. \mathbf{F}_{N} is the force of the scale pushing up on you, and reads the normal force. Since the scale reads 82 kg, if it were calibrated in Newtons, the normal force would be $F_{\rm N} = (82 \text{ kg})(9.8 \text{ m/s}^2) = 804 \text{ N}$. calibrated in Newtons, the normal force would be $F_N = (82 \text{ kg})(9.8 \text{ m/s}^2) = 804 \text{ N}$.
Write Newton's 2nd law in the vertical direction, with upward as positive.

$$
\sum F = F_{\rm N} - mg = ma \rightarrow a = \frac{F_{\rm N} - mg}{m} = \frac{804 \text{ N} - (65 \text{ kg})(9.8 \text{ m/s}^2)}{65 \text{ kg}} = 2.6 \text{ m/s}^2 \text{ upward}
$$

Since the acceleration is positive, the acceleration is upward.

72. To experience a gravity-type force, objects must be on the inside of the outer wall of the tube, so that there can be a centripetal force to move the objects in a circle. See the free-body diagram for an object on the inside of the outer wall, and a portion of the tube. The normal force of contact between the object and the wall must be maintaining the circular motion. Write Newton's $2nd$ law for the radial direction.

$$
\sum F_{\rm R} = F_{\rm N} = ma = mv^2/r
$$

If this is to have the same effect as Earth gravity, then we must also have that $F_N = mg$. Equate the two expressions for normal force and solve for the speed.
 $F_N = ma^2 I_N$, $mg = \sqrt{g_N} \sqrt{g_N} \sqrt{g_N} (g_N - g_N)^2 (g_N - g_N)^2 g_N g_N$

$$
F_{\rm N} = m v^2 / r = mg \rightarrow v = \sqrt{gr} = \sqrt{(9.8 \,\text{m/s}^2)(550 \,\text{m})} = 73 \,\text{m/s}
$$

$$
(73 \,\text{m/s}) \left(\frac{1 \,\text{rev}}{2\pi (550 \,\text{m})}\right) \left(\frac{86,400 \,\text{s}}{1 \,\text{d}}\right) = 1825 \,\text{rev/d} \approx \boxed{1.8 \times 10^3 \,\text{rev/d}}
$$
\mathbf{F}_{N}

73. (*a*) See the free-body diagram for the pilot in the jet at the bottom of the loop. For $a_R = v^2/r = 6g$, $a_{\rm R} = v^2/r = 6g$,

$$
v^2/r = 6.0g \rightarrow r = \frac{v^2}{6.0g} = \frac{\left[(1300 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) \right]^2}{6.0 (9.8 \text{ m/s}^2)} = \frac{2.2 \times 10^3 \text{ m}}{2.2 \times 10^3 \text{ m}}
$$

(*b*) The net force must be centripetal, to make the pilot go in a circle. Write Newton's 2^{nd} law for the vertical direction, with up as positive. The normal force is the apparent weight.

$$
\sum F_{\rm R} = F_{\rm N} - mg = mv^2/r
$$

The centripetal acceleration is to be $v^2/r = 6.0g$.

entripetal acceleration is to be
$$
v^2/r = 6.0g
$$
.
\n $F_N = mg + mv^2/r = 7mg = 7(78 \text{ kg})(9.80 \text{ m/s}^2) = 5350 \text{ N} = 5.4 \times 10^3 \text{ N}$

(*c*) See the free-body diagram for the pilot at the top of the loop. Notice that the normal force is down, because the pilot is upside down. Write Newton's $2nd$ law in the vertical direction, with down as positive. $2nd$ law in the vertical direction, with down as positive.

in the vertical direction, with down as positive.
\n
$$
F_{\rm R} = F_{\rm N} + mg = mv^2/r = 6mg \rightarrow F_{\rm N} = 5mg = 3.8 \times 10^3 \,\text{N}
$$

74. The force of gravity on an object at the surface is given by $F_{\text{grav}} = mg_{\text{p}}$. But by Newton's law of Universal Gravitation, the force of gravity on an object at the surface is given by $F_{\text{grav}} = G \frac{mM_{\text{planet}}}{r^2}$. $F_{\text{grav}} = G \frac{\text{planet}}{2}$. r^2 Universal Gravitation, the force of gravity on an object at the surface is given by $F_{\text{grav}} = G \frac{\rho_{\text{planet}}}{r^2}$.
Equate the expressions for the force of gravity and solve for the mass of the planet.

$$
G\frac{mM_{\text{planet}}}{r^2} = mg_{\text{p}} \rightarrow \left[M_{\text{planet}} = \frac{r^2g_{\text{p}}}{G}\right].
$$

75. (*a*) See the free-body diagram for the plumb bob. The attractive gravitational force on the plumb bob is $F_M = G \frac{mm_M}{R^2}$. Since the bob is not accelerating, the net $\frac{10}{2} \sum_{M} F_M$ *M* $F_{\text{M}} = G \frac{m m_{\text{M}}}{r^2}$. Since the bob is not accelerating, the net \overrightarrow{B} $\overrightarrow{F}_{\text{M}}$ D_M^2 **defines the contract of** θ force in any direction will be zero. Write the net force for both vertical and horizontal directions. Use $g = G \frac{M_{\text{Earth}}}{R_{\text{Earth}}^2}$ $\frac{M_{\text{Earth}}}{R_{\text{Earth}}^2}$ $g = G \frac{1}{2}$ Earth $R^2_{\text{\tiny Earth}}$

$$
\sum_{i=1}^{N} \vec{F}_{T} \cdot \vec{F}_{M}
$$

$$
\sum F_{\text{vertical}} = F_{\text{T}} \cos \theta - mg = 0 \rightarrow F_{\text{T}} = \frac{mg}{\cos \theta}
$$

$$
\sum F_{\text{horizontal}} = F_{\text{M}} - F_{\text{T}} \sin \theta = 0 \rightarrow F_{\text{M}} = F_{\text{T}} \sin \theta = mg \tan \theta
$$

$$
G \frac{mm_{\text{M}}}{D_{\text{M}}^2} = mg \tan \theta \rightarrow \theta = \tan^{-1} G \frac{m_{\text{M}}}{g D_{\text{M}}^2} = \left[\tan^{-1} \frac{m_{\text{M}} R_{\text{Earth}}^2}{M_{\text{Earth}} D_{\text{M}}^2} \right]
$$

(*b*) We estimate the mass of Mt. Everest by taking its volume times its mass density. If we approximate Mt. Everest as a cone with the same size diameter as height, then its volume is $V = \frac{1}{3}\pi r^2 h = \frac{1}{3}\pi (2000 \text{ m})^2 (4000 \text{ m}) = 1.7 \times 10^{10} \text{ m}^3$. The density is $\rho = 3 \times 10^3 \text{ kg/m}^3$. Find 3×10^3 kg/m³. Find the mass by multiplying the volume times the density.

$$
M = \rho V = (3 \times 10^3 \text{ kg/m}^3)(1.7 \times 10^{10} \text{ m}^3) = 5 \times 10^{13} \text{ kg}
$$

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) With $D = 5000$ m, use the relationship derived in part (a).

$$
\theta = \tan^{-1} \frac{M_{\rm M} R_{\rm Earth}^2}{M_{\rm Earth} D_M^2} = \tan^{-1} \frac{(5 \times 10^{13} \text{kg})(6.38 \times 10^6 \text{m})^2}{(5.97 \times 10^{24} \text{kg})(5000 \text{m})^2} = 8 \times 10^{-4} \text{ degrees}
$$

76. Since the curve is designed for a speed of 95 km/h, traveling at that speed would mean no friction is needed to round the curve. From Example 5-7 in the textbook, the no-friction banking angle is given by 2

$$
\theta = \tan^{-1} \frac{v^2}{rg} = \tan^{-1} \frac{\left[(95 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) \right]^2}{(67 \text{ m}) \left(9.8 \text{ m/s}^2 \right)} = 46.68^\circ
$$

Driving at a higher speed with the same radius means that more centripetal force will be required than is present by the normal force alone. That extra centripetal force will be supplied by a force of static friction, downward along the incline, as shown in the first free-body diagram for the car on the incline. Write Newton's 2^{nd} law in both the *x* and *y* directions. The car will have no acceleration in the *y* direction, and centripetal acceleration in the *x* direction. We also assume that the car is on the verge of skidding, so that the static frictional force has its maximum value of $F_f = \mu_s F_N$. .

$$
\sum F_y = F_N \cos \theta - mg - F_{fr} \sin \theta = 0 \rightarrow F_N \cos \theta - \mu_s F_N \sin \theta = mg \rightarrow
$$

\n
$$
F_N = \frac{mg}{(\cos \theta - \mu_s \sin \theta)}
$$

\n
$$
\sum F_x = F_N \sin \theta + F_{fr} \cos \theta = mv^2 / r \rightarrow F_N \sin \theta + \mu_s F_N \cos \theta = mv^2 / r \rightarrow
$$

\n
$$
F_N = \frac{mv^2 / r}{(\sin \theta + \mu_s \cos \theta)}
$$

Equate the two expressions for the normal force, and solve for the speed.

$$
\frac{mv^2/r}{\left(\sin\theta + \mu_s\cos\theta\right)} = \frac{mg}{\left(\cos\theta - \mu_s\sin\theta\right)} \rightarrow
$$
\n
$$
v = \sqrt{rg\frac{\left(\sin\theta + \mu_s\cos\theta\right)}{\left(\cos\theta - \mu_s\sin\theta\right)}} = \sqrt{\left(67 \text{ m}\right)\left(9.8 \text{ m/s}^2\right)\frac{\left(\sin 46.68^\circ + 0.30\cos 46.68^\circ\right)}{\left(\cos 46.68^\circ - 0.30\sin 46.68^\circ\right)}} = 36 \text{ m/s}
$$

Now for the slowest possible speed. Driving at a slower speed with the same radius means that less centripetal force will be required than that supplied by the normal force. That decline in centripetal force will be supplied by a force of static friction, upward along the incline, as shown in the second free-body diagram for the car on the incline. Write Newton's 2^{nd} law in both the *x* and *y* directions. The car will mg have no acceleration in the *y* direction, and centripetal acceleration in the *x* direction. We also assume that the car is on the verge of

skidding, so that the static frictional force has its maximum value of $F_f = \mu_sF_N$. .

$$
\sum F_y = F_N \cos \theta - mg + F_{\text{fr}} \sin \theta = 0 \rightarrow
$$

$$
F_N \cos \theta + \mu_s F_N \sin \theta = mg \rightarrow F_N = \frac{mg}{(\cos \theta + \mu_s \sin \theta)}
$$

$$
\sum F_x = F_{\text{N}} \sin \theta - F_{\text{fr}} \cos \theta = m v^2 / r \rightarrow F_{\text{N}} \sin \theta - \mu_s F_{\text{N}} \cos \theta = m v^2 / r \rightarrow
$$

$$
F_{\text{N}} = \frac{m v^2 / r}{(\sin \theta - \mu_s \cos \theta)}
$$

Equate the two expressions for the normal force, and solve for the speed.

$$
\frac{mv^2/r}{(\sin\theta - \mu_s \cos\theta)} = \frac{mg}{(\cos\theta + \mu_s \sin\theta)} \rightarrow
$$
\n
$$
v = \sqrt{rg \frac{(\sin\theta - \mu_s \cos\theta)}{(\cos\theta + \mu_s \sin\theta)}} = \sqrt{(67 \text{ m})(9.8 \text{ m/s}^2) \frac{(\sin 46.67^\circ - 0.30 \cos 46.67^\circ)}{(\cos 46.67^\circ + 0.30 \sin 46.67^\circ)}} = 19 \text{ m/s}
$$
\nThus the range is $\sqrt{19 \text{ m/s} \le v \le 36 \text{ m/s}}$, which is $\sqrt{68 \text{ km/h} \le v \le 130 \text{ km/h}}$.

77. For an object to be apparently weightless would mean that the object would have a centripetal acceleration equal to *g*. This is really the same as asking what the orbital period would be for an object orbiting the Earth with an orbital radius equal to the Earth's radius. To calculate, use 2

$$
g = a_c = v^2/R_{\text{Earth}}
$$
, along with $v = 2\pi R_{\text{Earth}}/T$, and solve for T.

$$
g = \frac{v^2}{R_{\text{Earth}}} = \frac{4\pi^2 R_{\text{Earth}}}{T^2} \quad \rightarrow \quad T = 2\pi \sqrt{\frac{R_{\text{Earth}}}{g}} = 2\pi \sqrt{\frac{6.38 \times 10^6 \text{ m}}{9.80 \text{ m/s}^2}} = 5.07 \times 10^3 \text{s} \left(\sim 84.5 \text{ min} \right)
$$

78. See the diagram for the two stars.

(*a*) The two stars don't crash into each other because of their circular motion. The force on them is centripetal, and maintains their circular motion. Another way to consider it is that the stars have a velocity, and the gravity force causes CHANGE in velocity, not actual

velocity. If the stars were somehow brought to rest and then released under the influence of their mutual gravity, they would crash into each other.

(*b*) Set the gravity force on one of the stars equal to the centripetal force, using the relationship that $v = 2\pi r/T = \pi d/T$, and solve for the mass.
 $v^2 = 2(\pi d/T)^2 = 2\pi^2 M$

$$
F_G = G \frac{M^2}{d^2} = F_R = M \frac{v^2}{d/2} = M \frac{2(\pi d/T)^2}{d} = \frac{2\pi^2 Md}{T^2} \rightarrow G \frac{M^2}{d^2} = \frac{2\pi^2 Md}{T^2} \rightarrow
$$

$$
M = \frac{2\pi^2 d^3}{GT^2} = \frac{2\pi^2 (8.0 \times 10^{10} \text{ m})^3}{(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2) (12.6 \text{ y} \times \frac{3.15 \times 10^7 \text{s}}{1 \text{ y}})^2} = 9.6 \times 10^{26} \text{ kg}
$$

79. The lamp must have the same speed and acceleration as the train. The forces on the lamp as the train rounds the corner are shown in the free-body diagram included. The tension in the suspending cord must not only hold the lamp up, but also provide the centripetal force needed to make the lamp move in a circle. Write Newton's $2nd$ law for the vertical direction, noting that the lamp is not accelerating vertically.

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$
\sum F_y = F_{\rm T} \cos \theta - mg = 0 \rightarrow F_{\rm T} = \frac{mg}{\cos \theta}
$$

The force moving the lamp in a circle is the horizontal portion of the tension. Write Newton's 2^{nd} law for that radial motion.

$$
\sum F_{\rm R} = F_{\rm T} \sin \theta = ma_{\rm R} = mv^2/r
$$

Substitute the expression for the tension from the first equation into the second equation, and solve for the speed.

$$
F_{\rm T} \sin \theta = \frac{mg}{\cos \theta} \sin \theta = mg \tan \theta = m v^2 / r \rightarrow
$$

$$
v = \sqrt{rg \tan \theta} = \sqrt{(235 \text{ m})(9.80 \text{ m/s}^2) \tan 17.5^\circ} = 26.9 \text{ m/s}
$$

80. For a body on the equator, the net motion is circular. Consider the free body diagram as shown. F_N is the normal force, which is the apparent weight. The net force must point to the center of the circle for the object to
be moving in a circular path at constant speed. Write Newton's 2^{nd} law with be moving in a circular path at constant speed. Write Newton's $2nd$ law with the inward direction as positive.
 $\sum F_{N}$ and F_{N} and $\sum F_{N}$ and $\sum F_{N}$

$$
\sum F_{R} = mg_{Jupiter} - F_{N} = m v^{2} / R_{Jupiter} \rightarrow
$$

$$
F_{N} = m \left(g_{Jupiter} - v^{2} / R_{Jupiter} \right) = m \left(G \frac{M_{Jupiter}}{R_{Jupiter}^{2}} - \frac{v^{2}}{R_{Jupiter}} \right)
$$

Use the fact that for a rotating object, $v = 2\pi r/T$.

$$
F_{_{\rm N}}=m\Biggl(G\,\frac{M_{_{\rm Jupiter}}}{R_{_{\rm Jupiter}}^2}\!-\!\frac{4\pi^2R_{_{\rm Jupiter}}}{T_{_{\rm Jupiter}}^2}\Biggr)
$$

Thus the perceived acceleration of the object on the surface of Jupiter is

$$
G \frac{M_{\text{Jupiter}}}{R_{\text{Jupiter}}^2} - \frac{4\pi^2 R_{\text{Jupiter}}}{T_{\text{Jupiter}}^2} = \left(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2\right) \frac{\left(1.9 \times 10^{27} \text{ kg}\right)}{\left(7.1 \times 10^7 \text{ m}\right)^2} - \frac{4\pi^2 \left(7.1 \times 10^7 \text{ m}\right)}{\left[\left(595 \text{ min}\right) \left(\frac{60 \text{ s}}{1 \text{ min}}\right)\right]^2}
$$

$$
= 22.94 \text{ m/s}^2 \left(\frac{1 g}{9.8 \text{ m/s}^2}\right) = 2.3 g \text{ s}
$$

Thus you would not be crushed at all. You would certainly feel "heavy", but not at all crushed.

81. The speed of an orbiting object is given by $v = \sqrt{GM/r}$, where *r* is the radius of the orbit, and *M* is the mass around which the object is orbiting. Solve the equation for *M.*

$$
v = \sqrt{GM/r}
$$
 $\rightarrow M = \frac{rv^2}{G} = \frac{(5.7 \times 10^{17} \text{ m})(7.8 \times 10^5 \text{ m/s})^2}{(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2)} = 5.2 \times 10^{39} \text{ kg}$

The number of solar masses is found by dividing the result by the solar mass.

$$
\text{\# solar masses} = \frac{M_{\text{galaxy}}}{M_{\text{Sun}}} = \frac{5.2 \times 10^{39} \text{ kg}}{2 \times 10^{30} \text{ kg}} = 2.6 \times 10^{9} \text{ solar masses}
$$

 $\mathbf{F}_{\scriptscriptstyle\rm N}$

82. A generic free-body diagram for the car at any of the three locations is shown. Write Newton's $2nd$ law for the vertical direction, with downward positive.

$$
\sum F = mg - F_{\rm N} = ma
$$

- (*a*) At point B, the net force is 0, so the acceleration is 0, and so $F_N = mg$. At point $\left\{mg\right\}$ mg . At point $\qquad \qquad \int mg$ A, the net force is positive, so $mg > F_N$, which is interpreted as a relatively small normal force. At point B, the net force is negative, so $mg < F_N$, which is interpreted as a relatively large normal force. And so $\boxed{F_{\text{NC}} > F_{\text{NB}} > F_{\text{NA}}}$. $F_{\text{NB}} > F_{\text{NA}}$. F_{NA} . . A construction of the construction of th *m***g**
- (*b*) The driver "feels heavy" when the normal force is larger than his weight, so the driver will feel heavy at point C. The driver "feels light" when the normal force is smaller than his weight, so the driver will feel light at point A. From feels heaviest to feels lightest, C, B, A.
- (*c*) In general, $mg F_y = mv^2/r$ if the car is executing a part of the road that is curved up or down with a radius of *R*. If the normal force goes to 0, then the car loses contact with the road. This happens if $mg = mv^2/r$ \rightarrow $v_{\text{max}} = \sqrt{gR}$. Any faster and the car will lose contact with the road.
- 83. (*a*) The speed of a satellite orbiting the Earth is given by $v = \sqrt{GM_{\text{Earth}}/r}$. For the GPS satellites, $r = R_{\text{net}} + (11.000)(1.852 \text{ km}) = 2.68 \times 10^7 \text{ m}$.

$$
r = R_{\text{Earth}} + (11,000)(1.852 \text{ km}) = 2.68 \times 10^{7} \text{ m}.
$$

$$
v = \sqrt{(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^{2} / \text{kg}^{2}) \frac{(5.97 \times 10^{24} \text{ kg})}{2.68 \times 10^{7} \text{ m}}} = 3.86 \times 10^{3} \text{ m/s}
$$

(*b*) The period can be found from the speed and the radius.

$$
v = 2\pi r/T
$$
 \rightarrow $T = \frac{2\pi r}{v} = \frac{2\pi (2.68 \times 10^7 \text{ m})}{3.86 \times 10^3 \text{ m/s}} = 4.36 \times 10^4 \text{ sec} = 12.1 \text{ hours}$

84. (*a*) The speed of an object orbiting a mass *M* is given by $v = \sqrt{GM/r}$. The mass of the asteroid is found by multiplying the density times the volume. The period of an object moving in a circular path is given by $T = 2\pi r/v$. Combine these relationships to find the period.

$$
M = \rho V = \left(2.3 \times 10^3 \frac{\text{kg}}{\text{m}^3}\right) \left(40000 \times 6000 \times 6000 \text{ m}^3\right) = 3.312 \times 10^{15} \text{kg}
$$

$$
T = \frac{2\pi r}{\sqrt{G \frac{M}{r}}} = \frac{2\pi \left(1.5 \times 10^4 \text{ m}\right)}{\sqrt{\left(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2\right) \frac{\left(3.312 \times 10^{15} \text{kg}\right)}{\left(1.5 \times 10^4 \text{ m}\right)}}} = 2.456 \times 10^4 \text{ sec}
$$

$$
\approx \boxed{2 \times 10^4 \text{ sec}} \approx 7 \text{ h}
$$

(*b*) If the asteroid were a sphere, then the mass would be given by $M = \rho V = \frac{4}{3}\pi \rho r^3$. Solve this for the radius.

$$
r = \left(\frac{3M}{4\pi\rho}\right)^{1/3} = \left(\frac{3\left(3.312 \times 10^{15}\,\text{kg}\right)}{4\pi\left(2.3 \times 10^3 \,\frac{\text{kg}}{\text{m}^3}\right)}\right)^{1/3} = 7005 \text{ m} \approx \boxed{7 \times 10^3 \text{ m}}
$$

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) The acceleration due to gravity is found from the mass and the radius.

$$
g = GM/r^2 = (6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2) \frac{(3.312 \times 10^{15} \text{ kg})}{(7005 \text{ m})^2} = 4.502 \times 10^{-3} \text{ m/s}^2
$$

$$
\approx 5 \times 10^{-3} \text{ m/s}^2
$$

- 85. The relationship between orbital speed and orbital radius for objects in orbit around the Earth is given by $v = \sqrt{GM_{\text{Earth}}/r}$. There are two orbital speeds involved – the one at the original radius, $v_0 = \sqrt{GM_{\text{Earth}}/r_0}$, and the faster speed at the reduced radius, $v = \sqrt{GM_{\text{Earth}}/(r_0 - \Delta r)}$.
	- $v = \sqrt{GM_{\text{Earth}}}/(r_{0} \Delta r).$ (*a*) At the faster speed, 25,000 more meters will be traveled during the "catch-up" time, *t*. Note that $r_0 = 6.38 \times 10^6 \text{ m} + 4 \times 10^5 \text{ m} = 6.78 \times 10^6 \text{ m}$.
		- $_{0}$ 0.00 μ 0 m + μ 0.00 m = 0.70 μ m. $r_0 = 6.38 \times 10^6 \,\mathrm{m} + 4 \times 10^5 \,\mathrm{m} = 6.78 \times 10^6 \,\mathrm{m}$.

$$
vt = v_0 t + 2.5 \times 10^4 \text{ m} \rightarrow \left(\sqrt{G \frac{M_{\text{Earth}}}{r_0 - \Delta r}}\right) t = \left(\sqrt{G \frac{M_{\text{Earth}}}{r_0}}\right) t + 2.5 \times 10^4 \text{ m} \rightarrow
$$

\n
$$
t = \frac{2.5 \times 10^4 \text{ m}}{\sqrt{GM_{\text{Earth}}}} \left(\frac{1}{\sqrt{r_0 - \Delta r}} - \frac{1}{\sqrt{r_0}}\right)
$$

\n
$$
= \frac{2.5 \times 10^4 \text{ m}}{\sqrt{\left(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2\right) \left(5.97 \times 10^{24} \text{ kg}\right)}} \left(\frac{1}{\sqrt{6.78 \times 10^6 \text{ m} - 1 \times 10^3 \text{ m}}} - \frac{1}{\sqrt{6.78 \times 10^6 \text{ m}}}\right)
$$

\n= 4.42 × 10⁴ s ≈ 12 h

(*b*) Again, 25,000 more meters must be traveled at the faster speed in order to catch up to the satellite.

$$
vt = v_0 t + 2.5 \times 10^4 \text{ m} \rightarrow \left(\sqrt{G \frac{M_{\text{Earth}}}{r_0 - \Delta r}}\right) t = \left(\sqrt{G \frac{M_{\text{Earth}}}{r_0}}\right) t + 2.5 \times 10^4 \text{ m} \rightarrow
$$

$$
\sqrt{\frac{1}{r_0 - \Delta r}} = \frac{1}{\sqrt{r_0}} + \frac{2.5 \times 10^4 \text{ m}}{t \sqrt{GM_{\text{Earth}}}} \rightarrow \sqrt{r_0 - \Delta r} = \left[\frac{1}{\sqrt{r_0}} + \frac{2.5 \times 10^4 \text{ m}}{t \sqrt{GM_{\text{Earth}}}}\right]^{-1} \rightarrow
$$

$$
\Delta r = r_0 + \left[\frac{1}{\sqrt{r_0}} + \frac{2.5 \times 10^4 \text{ m}}{t \sqrt{GM_{\text{Earth}}}}\right]^{-2} = 1755 \text{ m} \approx \boxed{1.8 \times 10^3 \text{ m}}
$$

86. (*a*) Use Kepler's 3rd law to relate the orbits of the Earth and the comet around the Sun.

$$
\left(\frac{r_{\text{comet}}}{r_{\text{Earth}}}\right)^3 = \left(\frac{T_{\text{comet}}}{T_{\text{Earth}}}\right)^2 \rightarrow r_{\text{comet}} = r_{\text{Earth}} \left(\frac{T_{\text{comet}}}{T_{\text{Earth}}}\right)^{2/3} = \left(1 \text{ AU}\right) \left(\frac{3000 \text{ y}}{1 \text{ y}}\right)^{2/3} = 208 \text{ AU}
$$

(*b*) The mean distance is the numeric average of the closest and farthest distances.

$$
208 \text{ AU} = \frac{1 \text{ AU} + r_{\text{max}}}{2} \rightarrow r_{\text{max}} = 415 \text{ AU}.
$$

(*c*) Refer to figure 5-29, which illustrates Kepler's second law. If the time for each shaded region is made much shorter, then the area of each region can be approximated as a triangle. The area of each triangle is half the "base" (speed of comet multiplied by the amount of time) times the "height" (distance from Sun). So we have the following.

Area_{min} = Area_{max}
$$
\rightarrow \frac{1}{2}(v_{min}t)r_{min} = \frac{1}{2}(v_{max}t)r_{max} \rightarrow
$$

\n $v_{min}/v_{max} = r_{max}/r_{min} = \boxed{415/1}$
\n87. Let us assume that each person has a mass of 70 kg (a weight of ~ 150 lb). We shall assume that the

people can be treated as point masses, and that their centers of mass are about 0.5 m apart. Finally, we assume that we can feel a gravitational force of about 1 N. The expression for the gravitational force becomes

$$
F = G \frac{m_1 m_2}{r^2} \quad \rightarrow \quad G = \frac{Fr^2}{m_1 m_2} = \frac{(1 \text{ N})(0.5 \text{ m})^2}{(70 \text{ kg})^2} = \boxed{5 \times 10^{-5} \text{ N} \cdot \text{m}^2/\text{kg}^2}.
$$

This is roughly one million times larger than *G* actually is.

88. The speed of rotation of the Sun about the galactic center, under the assumptions made, is given by

$$
v = \sqrt{G \frac{M_{\text{galaxy}}}{r_{\text{Sun orbit}}}} \text{ and so } M_{\text{galaxy}} = \frac{r_{\text{Sun orbit}} v^2}{G}. \text{ Substitute in the relationship that } v = 2\pi r_{\text{Sun orbit}} / T.
$$

$$
M_{\text{galaxy}} = \frac{4\pi^2 (r_{\text{Sun orbit}})^3}{GT^2} = \frac{4\pi^2 [(30,000)(9.5 \times 10^{15} \text{ m})]^3}{(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2) \left[(200 \times 10^6 \text{ y}) \left(\frac{3.15 \times 10^7 \text{ s}}{1 \text{ y}} \right)^2 \right]} = 3.452 \times 10^{41} \text{ kg} \approx 3 \times 10^{41} \text{ kg}
$$

The number of solar masses is found by dividing the result by the solar mass.

$$
\# \ \text{stars} = \frac{M_{\text{galaxy}}}{M_{\text{Sun}}} = \frac{3.452 \times 10^{41} \text{ kg}}{2.0 \times 10^{30} \text{ kg}} = 1.726 \times 10^{11} \approx \boxed{2 \times 10^{11} \text{ stars}}
$$

89. See the free-body diagram. $\theta = \tan^{-1} 0.25 / 0.50 = 27^\circ$. Because of $\binom{m}{m}$ the symmetry of the problem, the forces \mathbf{F}_{L} and \mathbf{F}_{R} cancel each other. and \mathbf{F}_R cancel each other. Likewise, the horizontal components of \vec{F}_{UR} and \vec{F}_{UL} cancel each other. Thus the only forces on the fifth mass will be the vertical components of \vec{F}_{UR} and \vec{F}_{UL} . These components are also equal, and so only one needs to be calculated, and then doubled. For the symmetry of the problem, the forces \vec{F}_L and \vec{F}_R cancel each other.

Likewise, the horizontal components of \vec{F}_{CR} and \vec{F}_{CR} . These components are also equal, and

so only one needs to be calculate

$$
=2(6.67\times10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2) \frac{(1.0 \text{ kg})^2}{\frac{5}{4}(0.50 \text{ m})^2}\cos 27^\circ = 3.8\times10^{-10} \text{ N}, \text{ upward}
$$

90. The gravitational force on the satellite is given by $F_{\text{grav}} = G \frac{M_{\text{Earth}}m}{r^2}$, where r is the distance of the r^2 , where *r* is the distance of the satellite from the center of the Earth. Since the satellite is moving in circular motion, then the net

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

we have $F_{\text{net}} = \frac{4\pi^2 mr}{T^2}$. Then, since gravity is the only force on the satellite, the two expressions for $F_{\text{net}} = \frac{4\pi^2 m r}{r^2}$. Then, since gravity is the only force on the satellite, the two expressions for T^2 and T^2 is the set of T is the set of T . Then, since gravity is the only force on the satellite, the two expressions for force can be equated, and solved for the orbit radius.

$$
G \frac{M_{\text{Earth}} m}{r^2} = \frac{4\pi^2 mr}{T^2} \rightarrow
$$

$$
r = \left(\frac{GM_{\text{Earth}} T^2}{4\pi^2}\right)^{1/3} = \left[\frac{(6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2)(6.0 \times 10^{24} \text{ kg})(6200 \text{ s})^2}{4\pi^2}\right]^{1/3} = 7.304 \times 10^6 \text{ m}
$$

(*a*) From this value the gravitational force on the satellite can be calculated.

$$
F_{\text{grav}} = G \frac{M_{\text{Earth}} m}{r^2} = (6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2) \frac{(6.0 \times 10^{24} \text{ kg})(5500 \text{ kg})}{(7.304 \times 10^6 \text{ m})^2} = 4.126 \times 10^4 \text{ N}
$$

$$
\approx 4.1 \times 10^4 \text{ N}
$$

(b) The altitude of the satellite above the Earth's surface is given by

$$
r - R_{\text{Earth}} = 7.304 \times 10^6 \,\text{m} - 6.38 \times 10^6 \,\text{m} = 9.2 \times 10^5 \,\text{m}.
$$

- 91. The radial acceleration is given by $a_R = v^2/r$. Substitute in the speed of the tip of the sweep hand, given by $v = 2\pi r/T$, to get $a_R = \frac{4\pi^2 r}{T^2}$. For the tip of the sweep hand, $r = 0.015$ m, and $T = 60$ sec. $4\pi^2 r$ Γ 4 \therefore 64 Γ 1 Γ 0.017 Γ 1.7 60 $R = \frac{1}{R^2}$. For the tip of the sweep nane, $P = 0.015$ m, and $T = 00$ see. $a_{R} = \frac{4\pi^{2}r}{r^{2}}$. For the tip of the sweep hand, $r = 0.015$ m, and $T = 60$ sec. T^2 **T** . For the tip of the sweep hand, $r = 0.015$ m, and $T = 60$ sec. 2π $4\pi^2$ (0.015 m) $\frac{4}{2}$ $\frac{2}{2}$ 2 $\left(\epsilon_0\right)^2$ $\left(\epsilon_1\right)^2$ $4\pi^2 r$ $4\pi^2 (0.015 \text{ m})$ 1.6×10^{-4} m/s². $R = T^2$ (60 s)² $-\frac{[1.6 \times 10^{6} \text{ m}]s}{[1.6 \times 10^{6} \text{ m}]}$. $a_{R} = \frac{4\pi^{2}r}{r^{2}} = \frac{4\pi^{2}(0.015 \text{ m})}{r^{2}} = 1.6 \times 10^{-4} \text{ m/s}^{2}.$ T^2 (60 s)² . A construction of the construction of th
- 92. A free-body diagram for the sinker weight is shown. *L* is the length of the string actually swinging the sinker. The radius of the circle of motion is moving is $r = L \sin \theta$.
Write Newton's 2nd law for the vertical direction, noting that the sinker is not accelerating vertically. Take up to be positive.

$$
\sum F_y = F_{\rm T} \cos \theta - mg = 0 \rightarrow F_{\rm T} = \frac{mg}{\cos \theta}
$$

The radial force is the horizontal portion of the tension. Write Newton's $2nd$ law for the radial motion.

$$
\sum F_{\rm R} = F_{\rm T} \sin \theta = ma_{\rm R} = m v^2 / r
$$

Substitute the tension from the vertical equation, and the relationships $r = L \sin \theta$ and $v = 2\pi r/T$.

$$
F_{\rm T} \sin \theta = m v^2 / r \rightarrow \frac{mg}{\cos \theta} \sin \theta = \frac{4\pi^2 m L \sin \theta}{T^2} \rightarrow \cos \theta = \frac{gT^2}{4\pi^2 L}
$$

$$
\theta = \cos^{-1} \frac{gT^2}{4\pi^2 L} = \cos^{-1} \frac{(9.8 \text{ m/s}^2)(0.50 \text{ s})^2}{4\pi^2 (0.25 \text{ m})} = 76^\circ
$$

93. From Example 5-7 in the textbook, the no-friction banking angle is given by $\theta = \tan^{-1} \frac{v_0^2}{Rg}$. The $1 \frac{V_0}{I}$ The $\tan^{-1} \frac{v_0}{v_0}$. The v_0^2 *Rg* . The

centripetal force in this case is provided by a component of the normal force. Driving at a higher speed with the same radius requires more centripetal force than that provided by the normal force alone. The additional centripetal force is supplied by a force of static friction, downward along the incline. See the free-body diagram for the car on the incline. The center of the circle of the car's motion is to the right of the car in the diagram. Write Newton's 2^{nd} law in both the *x* and *y* directions. The car $m\vec{g}$ will have no acceleration in the *y* direction, and centripetal acceleration in the *x* direction. Assume that the car is on the verge of skidding, so that the static frictional force has its maximum value of $F_{\text{fr}} = \mu_s F_{\text{N}}$. .

$$
\sum F_y = F_N \cos \theta - mg - F_{\text{fr}} \sin \theta = 0 \rightarrow F_N \cos \theta - \mu_s F_N \sin \theta = mg \rightarrow
$$

\n
$$
F_N = \frac{mg}{(\cos \theta - \mu_s \sin \theta)}
$$

\n
$$
\sum F_x = F_R = F_N \sin \theta + F_{\text{fr}} \cos \theta = mv^2/R \rightarrow F_N \sin \theta + \mu_s F_N \cos \theta = mv^2/R \rightarrow
$$

\n
$$
F_N = \frac{mv^2/R}{(\sin \theta + \mu_s \cos \theta)}
$$

Equate the two expressions for the normal force, and solve for the speed, which is the maximum speed that the car can have.

$$
\frac{mv^2/R}{(\sin\theta + \mu_s \cos\theta)} = \frac{mg}{(\cos\theta - \mu_s \sin\theta)} \rightarrow
$$

$$
v_{\text{max}} = \sqrt{Rg \frac{\sin\theta}{\cos\theta} \frac{(1 + \mu_s/\tan\theta)}{(1 - \mu_s \tan\theta)}} = v_0 \sqrt{\frac{(1 + Rg\mu_s/v_0^2)}{(1 - \mu_s v_0^2/Rg)}}
$$

Driving at a slower speed with the same radius requires less centripetal force than that provided by the normal force alone. The $\vec{F}_{\text{f}_{\text{f}_{\text{f}}}}$ decrease in centripetal force is supplied by a force of static friction, upward along the incline. See the free-body diagram for the car on the incline. Write Newton's 2^{nd} law in both the *x* and *y* directions. The car will have no acceleration in the *y* direction, and centripetal map acceleration in the *x* direction. Assume that the car is on the verge of skidding, so that the static frictional force has its maximum value of

$$
F_{\text{fr}} = \mu_s F_{\text{N}}.
$$

\n
$$
\sum F_y = F_{\text{N}} \cos \theta - mg + F_{\text{fr}} \sin \theta = 0 \rightarrow
$$

\n
$$
F_{\text{N}} \cos \theta + \mu_s F_{\text{N}} \sin \theta = mg \rightarrow F_{\text{N}} = \frac{mg}{(\cos \theta + \mu_s \sin \theta)}
$$

\n
$$
\sum F_x = F_{\text{R}} = F_{\text{N}} \sin \theta - F_{\text{fr}} \cos \theta = mv^2/R \rightarrow F_{\text{N}} \sin \theta - \mu_s F_{\text{N}} \cos \theta = mv^2/R \rightarrow
$$

\n
$$
F_{\text{N}} = \frac{mv^2/R}{(\sin \theta - \mu_s \cos \theta)}
$$

Equate the two expressions for the normal force, and solve for the speed.

$$
\frac{mv^2/R}{(\sin\theta - \mu_s \cos\theta)} = \frac{mg}{(\cos\theta + \mu_s \sin\theta)} \rightarrow
$$
\n
$$
v_{\min} = \sqrt{Rg \frac{\sin\theta}{\cos\theta} \frac{(1 - \mu_s/\tan\theta)}{(1 + \mu_s \tan\theta)}} = v_0 \sqrt{\frac{(1 - \mu_s Rg/v_0^2)}{(1 + \mu_s v_0^2/Rg)}}
$$
\nThus\n
$$
v_{\min} = v_0 \sqrt{\frac{(1 - \mu_s Rg/v_0^2)}{(1 + \mu_s v_0^2/Rg)}} \quad \text{and} \quad v_{\max} = v_0 \sqrt{\frac{(1 + Rg\mu_s/v_0^2)}{(1 - \mu_s v_0^2/Rg)}}.
$$

94. The speed of the train is $(160 \text{ km/h}) \left(\frac{1 \text{ m/s}}{3.6 \text{ km/h}} \right) = 44.44 \text{ m/s}$ 1 m/s $\qquad \qquad$ 160 km/h $\left| \frac{120 \text{ km}}{100 \text{ km/h}} \right| = 44.44 \text{ m/s}$ 3.6 km/h $\overline{}$

(*a*) If there is no tilt, then the friction force must supply the entire centripetal force on the passenger.

$$
F_{\rm R} = m v^2 / R = \frac{(75 \text{ kg})(44.44 \text{ m/s})^2}{(620 \text{ m})} = 238.9 \text{ N} \approx 2.4 \times 10^2 \text{ N}
$$

(*b*) For the banked case, the normal force will contribute to the radial force needed. Write Newton's $2nd$ law for both the *x* and *y* directions. The *y* acceleration is zero, and the *x* acceleration is radial. acceleration is zero, and the *x* acceleration is radial.
 $\sum \vec{F}_{N} = F_{S} \cos \theta$, $m\vec{g} = F_{S} \sin \theta = 0$, $\sum \vec{F}_{S} = \frac{mg + F_{fs} \sin \theta}{m}$

$$
\sum F_y = F_N \cos \theta - mg - F_{\text{fr}} \sin \theta = 0 \rightarrow F_N = \frac{mg + F_{\text{fr}} \sin \theta}{\cos \theta}
$$

$$
\sum F_x = F_N \sin \theta + F_{\text{fr}} \cos \theta = mv^2/r
$$

. A construction of the construction of th

Substitute the expression for the normal force from the *y* equation into the *x* equation, and solve for the friction force.

$$
\frac{mg + F_{\text{fr}} \sin \theta}{\cos \theta} \sin \theta + F_{\text{fr}} \cos \theta = mv^2 / r \rightarrow
$$
\n
$$
(mg + F_{\text{fr}} \sin \theta) \sin \theta + F_{\text{fr}} \cos^2 \theta = m \frac{v^2}{r} \cos \theta \rightarrow
$$
\n
$$
F_{\text{fr}} = m \left(\frac{v^2}{r} \cos \theta - g \sin \theta \right)
$$
\n
$$
= (75 \text{ kg}) \left[\frac{(44.44 \text{ m/s})^2}{620 \text{ m}} \cos 8.0^\circ - (9.80 \text{ m/s}^2) \sin 8.0^\circ \right] = 134 \text{ N} \approx \boxed{1.3 \times 10^2 \text{ N}}
$$

CHAPTER 6: Work and Energy

Answers to Questions

- 1. Some types of physical labor, particularly if it involves lifting objects, such as shoveling dirt or carrying shingles up to a roof, are "work" in the physics sense of the word. Or, pushing a lawn mower would be work corresponding to the physics definition. When we use the word "work" for employment, such as "go to work" or "school work", there is often no sense of physical labor or of moving something through a distance by a force.
- 2. Since "centripetal" means "pointing to the center of curvature", then a centripetal force will not do work on an object, because if an object is moving in a curved path, by definition the direction towards the center of curvature is always perpendicular to the direction of motion. For a force to do work, the force must have a component in the direction of displacement. So the centripetal force does no work.
- 3. The normal force can do work on an object if the normal force has a component in the direction of displacement of an object. If someone were to jump up in the air, then the floor pushing upward on the person (the normal force) would do positive work and increase the person's kinetic energy. Likewise when they hit the floor coming back down, the force of the floor pushing upwards (the normal force) would do negative work and decrease the person's kinetic energy.
- 4. The woman does work by moving the water with her hands and feet, because she must exert a force to move the water some distance. As she stops swimming and begins to float in the current, the current does work on her because she gains kinetic energy. Once she is floating the same speed as the water, her kinetic energy does not change, and so no net work is being done on her.
- 5. The kinetic force of friction opposes the relative motion between two objects. As in the example suggested, as the tablecloth is pulled from under the dishes, the relative motion is for the dishes to be left behind as the tablecloth is pulled, and so the kinetic friction opposes that and moves the dishes in the same direction as the tablecloth. This is a force that is in the direction of displacement, and so positive work is done. Also note that the cloth is moving faster than the dishes in this case, so that the friction is kinetic, not static.
- 6. While it is true that no work is being done on the wall by you, there is work being done inside your arm muscles. Exerting a force via a muscle causes small continual motions in your muscles, which is work, and which causes you to tire. An example of this is holding a heavy load at arm's length. While at first you may hold the load steady, after a time your arm will begin to shake, which indicates the motion of muscles in your arm.
- 7. (*a*) In this case, the same force is applied to both springs. Spring 1 will stretch less, and so more work is done on spring 2.
	- (*b*) In this case, both springs are stretched the same distance. It takes more force to stretch spring 1, and so more work is done on spring 1.
- 8. At point C the block's speed will be less than $2v_B$. The same amount of work was done on the block in going from A to B as from B to C since the force and the displacement are the same for each segment. Thus the change in kinetic energy will be the same for each segment. From A to B, the

block gained $\frac{1}{2}mv_B^2$ of kinetic energy. If the same amount is gained from B to C, then the total kinetic energy at C is $\frac{1}{2}mv_c^2 = 2(\frac{1}{2}mv_B^2)$ which results in $v_c = \sqrt{2}v_B$, or $v_c \approx 1.4v_B$ $v_{\rm c} = \sqrt{2} v_{\rm B}$, or $v_{\rm c} \approx 1.4 v_{\rm B}$ $v_c \approx 1.4v_B$

- 9. Your gravitational PE will change according to $\Delta PE = mg\Delta y$. If we choose some typical values of $m = 80 \text{ kg}$ and $\Delta y = 0.75 \text{ m}$, then $\Delta PE = (80 \text{ kg})(9.8 \text{ m/s}^2)(0.75 \text{ m}) = 590 \text{ J}$
- 10. Since each balloon has the same initial kinetic energy, and each balloon undergoes the same overall change in gravitational PE, each balloon will have the same kinetic energy at the ground, and so each one has the same speed at impact.
- 11. The two launches will result in the same largest angle. Applying conservation of energy between the launching point and the highest point, we have $E_1 = E_2 \rightarrow \frac{1}{2}mv^2 + mgh = mgh_{\text{max}}$. The direction of the launching velocity does not matter, and so the same maximum height (and hence maximum angle) will results from both launches. Also, for the first launch, the ball will rise to some maximum height and then come back to the launch point with the same speed as when launched. That then exactly duplicates the second launch.
- 12. The spring can leave the table if it is compressed enough. If the spring is compressed an amount x_0 , The spring can leave the table if it is compressed enough. If the spring is compressed an amount x_0 , then the gain in elastic PE is $\frac{1}{2}kx_0^2$. As the spring is compressed, its center of mass is lowered by some amount. If the spring is uniform, then the center of mass is lowered by $x_0/2$, and the amount $x_0/2$, and the amount of decrease in gravitational PE is $\frac{1}{2}$ *mgx*₀. If the gain in elastic PE is more than the loss in gravitational PE, so that $\frac{1}{2}kx_0^2 > \frac{1}{2}mgx_0$ or $x_0 > mg/k$, then the released spring should rise up off of the table, because there is more than enough elastic PE to restore the spring to its original position. That extra elastic energy will enable the spring to "jump" off the table – it can raise its center of mass to a higher point and thus rise up off the table. Where does that "extra" energy come from? From the work you did in compressing the spring.
- 13. If the instructor releases the ball without pushing it, the ball should return to exactly the same height (barring any dissipative forces) and just touch the instructor's nose as it stops. But if the instructor pushes the ball, giving it extra kinetic energy and hence a larger total energy, the ball will then swing to a higher point before stopping, and hit the instructor in the face when it returns.
- 14. When water at the top of a waterfall falls to the pool below, initially the water's gravitational PE is turned into kinetic energy. That kinetic energy then can do work on the pool water when it hits it, and so some of the pool water is given energy, which makes it splash upwards and outwards and creates outgoing water waves, which carry energy. Some of the energy will become heat, due to viscous friction between the falling water and the pool water. Some of the energy will become kinetic energy of air molecules, making sound waves that give the waterfall its "roar".
- 15. Start the description with the child suspended in mid-air, at the top of a hop. All of the energy is gravitational PE at that point. Then, the child falls, and gains kinetic energy. When the child reaches the ground, most of the energy is kinetic. As the spring begins to compress, the kinetic energy is changed into elastic PE. The child also goes down a little bit further as the spring compresses, and so more gravitational PE is also changed into elastic PE. At the very bottom of a hop, the energy is all elastic PE. Then as the child rebounds, the elastic PE is turned into kinetic energy and gravitational PE. When the child reaches the top of the bounce, all of the elastic PE has

^{© 2005} Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

been changed into gravitational PE, because the child has a speed of 0 at the top. Then the cycle starts over again. Due to friction, the child must also add energy to the system by pushing down on the pogo stick while it is on the ground, getting a more forceful reaction from the ground.

- 16. As the skier goes down the hill, the gravitational PE is transformed mostly into kinetic energy, and small amount is transformed into heat energy due to the friction between the skis and the snow and air friction. As the skier strikes the snowdrift, the kinetic energy of the skier turns into kinetic energy of the snow (by making the snow move), and also into some heat from the friction in moving through the snowdrift.
- 17. (*a*) If there is no friction to dissipate any of the energy, then the gravitational PE that the child has at the top of the hill all turns into kinetic energy at the bottom of the hill. The same kinetic energy will be present regardless of the slope – the final speed is completely determined by the height. The time it takes to reach the bottom of the hill will be longer for a smaller slope.
	- (*b*) If there is friction, then the longer the path is, the more work that friction will do, and so the slower the speed will be at the bottom. So for a steep hill, the sled will have a greater speed at the bottom than for a shallow hill.
- 18. Stepping on the log requires that the entire body mass be raised up the height of the log, requiring work (that is not recoverable) proportional to the entire body mass. Stepping over the log only requires the raising of the legs, making for a small mass being raised and thus less work. Also, when jumping down, energy is expended to stop the "fall" from the log. The potential energy that you had at the top of the log is lost when coming down from the log.
- 19. If we assume that all of the arrow's kinetic energy is converted into work done against friction, then the following relationship exists:
 $W = \Delta K F = K F = K F \implies F d \cos 180^\circ = \pm m v^2 = \pm m v^2 \implies F d = \pm m v^2 \implies$

$$
W = \Delta KE = KE_f - KE_i \rightarrow F_{\text{fr}}d \cos 180^\circ = \frac{1}{2}mv_f^2 - \frac{1}{2}mv_0^2 \rightarrow -F_{\text{fr}}d = -\frac{1}{2}mv_0^2 \rightarrow d = \frac{mv_0^2}{2F_{\text{fr}}}
$$

Thus the distance is proportional to the square of the initial velocity. So if the initial velocity is doubled, the distance will be multiplied by a factor of 4. Thus the faster arrow penetrates 4 times further than the slower arrow.

- 20. (*a*) Consider that there is no friction to dissipate any energy. Start the pendulum at the top of a swing, and define the lowest point of the swing as the zero location for gravitational PE. The pendulum has maximum gravitational PE at the top of a swing. Then as it falls, the gravitational PE is changed to kinetic energy. At the bottom of the swing, the energy is all kinetic energy. Then the pendulum starts to rise, and kinetic energy is changed to gravitational PE. Since there is no dissipation, all of the original gravitational PE is converted to kinetic energy, and all of the kinetic energy is converted to gravitational PE. The pendulum rises to the same height on both sides of every swing, and reaches the same maximum speed at the bottom on every swing.
	- (*b*) If there is friction to dissipate the energy, then on each downward swing, the pendulum will have less kinetic energy at the bottom than it had gravitational PE at the top. And then on each swing up, the pendulum will not rise as high as the previous swing, because energy is being lost to frictional dissipation any time the pendulum is moving. So each time it swings, it has a smaller maximum displacement. When a grandfather clock is wound up, a weight is elevated so that it has some PE. That weight then falls at the proper rate to put energy back in to the pendulum to replace the energy that was lost to dissipation.

- 21. The superball cannot rebound to a height greater than its original height when dropped. If it did, it would violate conservation of energy. When a ball collides with the floor, the KE of the ball is converted into elastic PE by deforming the ball, much like compressing a spring. Then as the ball springs back to its original shape, that elastic PE is converted to back to KE. But that process is "lossy" – not all of the elastic PE gets converted back to KE. Some of the PE is lost, primarily to friction. The superball rebounds higher than many other balls because it is less "lossy" in its rebound than many other materials.
- 22. The work done to lift the suitcase is equal to the change in PE of the suitcase, which is the weight of the suitcase times the change in height (the height of the table).
	- (*a*) Work does NOT depend on the path, as long as there are no non-conservative forces doing work.
	- (*b*) Work does NOT depend on the time taken.
	- (*c*) Work DOES depend on the height of the table the higher the table, the more work it takes to lift the suitcase.
	- (*d*) Work DOES depend on the weight of the suitcase the more the suitcase weighs, the more work it takes to lift the suitcase.
- 23. The power needed to lift the suitcase is the work required to lift the suitcase, divided by the time that it takes.
	- (*a*) Since work does NOT depend on the path, the power will not depend on the path either, assuming the time is the same for all paths.
	- (*b*) The power DOES depend on the time taken. The more time taken, the lower the power needed.
	- (*c*) The power needed DOES depend on the height of the table. A higher table requires more work to lift the suitcase. If we assume that the time to lift the suitcase is the same in both cases, then to lift to the higher table takes more power.
	- (*d*) The power DOES depend on the weight of the suitcase. A heavier suitcase requires more force to lift, and so requires more work. Thus the heavier the suitcase, the more power is needed to lift it (in the same amount of time).
- 24. The climber does the same amount of work whether climbing straight up or via a zig-zag path, ignoring dissipative forces. But if a longer zig-zag path is taken, it takes more time to do the work, and so the power output needed from the climber is less. That will make the climb easier. It is easier for the human body to generate a small amount of power for long periods of time rather than to generate a large power for a small period of time.
- 25. Assuming that there are no dissipative forces to consider, for every meter that the load is raised, two meters of rope must be pulled up. This is due to the rope passing over the bottom pulley. The work done by the person pulling must be equal to the work done on the piano. Since the force on the piano is twice that exerted by the person pulling, and since work is force times distance, the person must exert their smaller force over twice the distance that the larger pulley force moves the piano.

Solutions to Problems

1. The force and the displacement are both downwards, so the angle between them is 0° . wnwards, so the angle between them is 0^o.

² $\left(2.80 \text{ m}\right)$ and 0° .

$$
W_{\rm G} = mgd\cos\theta = (265\text{ kg})(9.80\text{ m/s}^2)(2.80\text{ m})\cos 0^\circ = 7.27 \times 10^3 \text{ J}
$$

 \mathbf{F}_{fr} **F**_P

 \mathbf{F}_{P}

 \vec{x}

 \vec{y} | \vec{F}_n

*m***g**

2. The minimum force required to lift the firefighter is equal to his weight. The force and the displacement are both upwards, so the angle between them is 0° . . A construction of the construction of th

$$
W_{\text{climb}} = F_{\text{climb}} d \cos \theta = mgd \cos \theta = (65.0 \text{ kg})(9.80 \text{ m/s}^2)(20.0 \text{ m}) \cos 0^\circ = 1.27 \times 10^4 \text{ J}
$$

3. (*a*) See the free-body diagram for the crate as it is being pulled. Since the crate is not accelerating horizontally, $F_p = F_f = 230$ N. The work done to move it across the floor is the work done by the pulling force. The angle between the pulling force and the direction of motion is 0° . force and the direction of motion is 0°.
 \vec{F} $(m\vec{g})$

$$
W_{\rm p} = F_{\rm p} d \cos 0^{\circ} = (230 \text{ N})(4.0 \text{ m})(1) = 9.2 \times 10^2 \text{ J}
$$

(*b*) See the free-body diagram for the crate as it is being lifted. Since the crate is not accelerating vertically, the pulling force is the same magnitude as the weight. The angle between the pulling force and the direction of motion is 0° . vulling force and the direction of motion is 0° .

$$
W_{\rm p} = F_{\rm p}d\cos 0^{\circ} = mgd = (1300\,\text{N})(4.0\,\text{m}) = 5.2 \times 10^3\,\text{J}
$$

4. Draw a free-body diagram for the crate as it is being pushed across the floor. Since it is not accelerating vertically, $F_N = mg$. Since it is not accelerating F_P horizontally, $F_{\rm p} = F_{\rm fr} = \mu_k F_{\rm N} = \mu_k mg$. The work done to move it across the floor is the work done by the pushing force. The angle between the pushing force and the direction of motion is 0° . of motion is 0°.
 \mathbf{F}_{N} \mathbf{F}_{N} \mathbf{F}_{N} \mathbf{F}_{N} \mathbf{F}_{N}

$$
W_{\text{push}} = F_{\text{push}} d \cos 0^{\circ} = \mu_k mgd (1) = (0.50)(160 \text{ kg})(9.80 \text{ m/s}^2)(10.3 \text{ m})
$$

=
$$
8.1 \times 10^3 \text{ J}
$$

5. Since the acceleration of the box is constant, use Eq. 2-11b to find the distance moved. Assume that the box starts from rest.

$$
\Delta x = x - x_0 = v_0 t + \frac{1}{2} a t^2 = 0 + \frac{1}{2} (2.0 \, \text{m/s}^2) (7 \, \text{s})^2 = 49 \, \text{m}
$$

Then the work done in moving the crate is
 $W = F \Delta x \cos 0^\circ = ma\Delta x = (5 \text{ kg})(2.0 \text{ m/s}^2)(49 \text{ m}) = (4.9 \times 10^2 \text{ J})$

6. The first book is already in position, so no work is required to position it. The second book must be moved upwards by a distance *d*, by a force equal to its weight, *mg*. The force and the displacement are in the same direction, so the work is *mgd*. The third book will need to be moved a distance of 2*d* by the same size force, so the work is 2*mgd*, This continues through all seven books, with each needing to be raised by an additional amount of *d* by a force of *mg*. The total work done is $W_n = F_n d \cos 0^\circ = (230 \text{ N})(4.0 \text{ m})(1) = \frac{10.2 \times 10^2 \text{ J}}{9.2 \times 10^2 \text{ J}}$

the free-body diagram for the crate as it is being lifted. Since the crate is not

reacting vertically, the pulling force is the same magnitude as th

$$
W = mgd + 2mgd + 3mgd + 4mgd + 5mgd + 6mgd + 7mgd
$$

$$
=28mgd = 28(1.7 \text{ kg})(9.8 \text{ m/s}^2)(0.043 \text{ m}) = 2.0 \times 10^1 \text{ J}.
$$

-
- 7. Consider the diagram shown. If we assume that the man pushes straight down on the end of the lever, then the work done by the man (the "input" work) is given by $W_1 = F_1 h_1$. The object moves a shorter distance, as seen from the diagram, and so $W_0 = F_0 h_0$. shorter distance, as seen from the diagram, and so $W_0 = F_0 h_0$.

Equate the two amounts of work.
 $F_0 = F h_0$, $F_0 = h_1$

$$
F_{\rm o}h_{\rm o} = F_{\rm i}h_{\rm i} \rightarrow \frac{F_{\rm o}}{F_{\rm i}} = \frac{h_{\rm i}}{h_{\rm o}}
$$

But by similar triangles, we see that $\frac{h_1}{h_1} = \frac{l_1}{l_1}$, and so $\left| \frac{F_0}{h_1} \right|$. $\begin{bmatrix} 0 & \mathbf{0} \end{bmatrix}$ $\begin{bmatrix} 1 & \mathbf{0} \ \mathbf{0} & \mathbf{0} \end{bmatrix}$ h_0 l_0 F_{I} l_0 \mathbf{I} \mathbf{O} F_{I} l_{Ω}

- 8. The piano is moving with a constant velocity down the plane. \vec{F}_p is the force of the man pushing on the piano.
	- (*a*) Write Newton's $2^{n\bar{d}}$ law on each direction for the piano, with an acceleration of 0.

y similar triangles, we see that
$$
\frac{h_1}{h_0} = \frac{l_1}{l_0}
$$
, and so $\frac{F_0}{F_1} = \frac{l_1}{l_0}$.
\n $\frac{F_0}{F_1}$
\n $\frac{F_0}{F_2}$
\nof the man pushing that a constant velocity down the plane. \vec{F}_p is the
\nof the man pushing that the piano, with an
\nacceleration of 0.
\n $\sum F_y = F_s - mg \cos \theta = 0 \rightarrow F_s = mg \cos \theta$
\n $\sum F_y = mg \sin \theta - F_x - F_u = 0 \rightarrow$
\n $F_y = mg \sin \theta - F_x = mg (\sin \theta - \mu_k \cos \theta)$
\n $= (330 \text{ kg})(9.80 \text{ m/s}^2)(\sin 28^\circ - 0.40 \cos 28^\circ) = 3.8 \times 10^2 \text{ N}$
\nThe work done by the man is the work done by \vec{F}_p . The angle between \vec{F}_p and the direction of
\nmotion is 180°.
\n $W_p = F_p d \cos 180^\circ = -(380 \text{ N})(3.6 \text{ m}) = \frac{[-1.4 \times 10^3 \text{ J}]}{[-1.4 \times 10^3 \text{ J}]}$.
\nThe angle between \vec{F}_k and the direction of motion is 180°.
\n $W_k = F_k d \cos 180^\circ = -\mu_k mgd \cos \theta = -(0.40)(330 \text{ kg})(9.8 \text{ m/s}^2)(3.6 \text{ m}) \cos 28^\circ$
\n $= \frac{[-4.1 \times 10^3 \text{ J}]}{[-4.1 \times 10^3 \text{ J}]}$.
\nThe angle between the force of gravity and the direction of motion is 62°. So the work done by
\ngravity is
\n $W_G = F_G d \cos 62^\circ = mgd \cos 62^\circ = (330 \text{ kg})(9.8 \text{ m/s}^2)(3.6 \text{ m}) \cos 62^\circ = \frac{[5.5 \times 10^3 \text{ J}]}{[5.5 \times 10^3]}$.
\nSince the piano is unacceptable, the net force on the piano, and so the net work done
\n $W_{\text{net}} =$

is the
an

$$
\overrightarrow{F}_{\text{fr}}
$$

(*b*) The work done by the man is the work done by \mathbf{F}_P . The angle between \mathbf{F}_P and the direction of motion is 180° . .
